A Warm Welcome from the Conference President

Welcome to the ESB 2014 and Liverpool. Thank you to everyone that has contributed to putting together our varied, exciting and thought provoking programme of open paper sessions, symposia and social events. For me, the purpose of the ESB annual meeting is to have a real place and point in our busy research lives to come together and “cut to the chase”. In a multidisciplinary applied subject such as ours that stands as a keystone of the knowledgebase for future medicine to provide for healthy ageing and independent living, it is more important than ever to meet as a community (“scientific family”) and present and discuss first-hand what we have done, what worked and what did not.

We’ve provided everything you need; the infrastructure, the timetable and the facilities so you can focus and concentrate on presenting and discussing the detail, the issues and the future. Enjoy yourselves, work hard we’ve a lot to do to realise our collective potential.

OUR future health needs us..... 16% of the population is born disabled, 84% at birth aren’t disabled yet! If nothing else kills us on our journey through life, we will all age (more or less graciously) and with that comes, to put it bluntly disabilities. Mankind as a society can’t afford for each of us to live longer and become increasingly disabled and more dependant. We as Biomaterials Scientists can address this, all of us know we can, the question is how fast can we do it? It’ll be faster together.

A handwritten signature in black ink, appearing to read 'John Hunt'.

Conference President: John Hunt

ESB President's Address

Dear all,

It is almost metronomic, is it not, the time with which the UK community hosts the ESB annual conference; London 2001, Brighton 2007 and this year another iconic city in Britain, Liverpool.

I have been reflecting on the trajectory of our Society in the last few years with its constant travelling from Country to Country. The Council has been changing its members, the conference delegates have been growing in numbers reaching out to colleagues around the world and opening its doors to an increasing number of young scientists.

But what's about our scientific progress? What's about the life of our patient's? What's the understanding or even the simple perception that the public, industry and policy makers have of us scientists and the work we do? Well! We may see the glass half full or half empty, but this is not the point. Interpreting and analysing the present it is important, but it is more important to set the vision for the future of our work as individual scientists, research groups, national societies and of course as ESB. And for scientists the vision for the future has to be ambitious, pioneering new ways of thinking, rooted in the service of our patients.

An honest, balanced assessment (I hope you share it) tells us that in all these years our biomaterials have reached significant achievements. Just to mention few of our exciting attainments, we have entered the world of the nano-scale, we have enabled the regeneration of tissues and developed theranostics. At the same time, the translation of this innovation is lacking behind partly because of our mistakes, certainly because of the constraints of the current political and economic environment. As ESB we have been working hard to improve the service and support to all our members, but we recognise that still a lot can be and has to be done for you and for your research. We look forward to explaining our plans at our General Assembly.

In this respect, I feel that the organisers of the ESB2014 have built a programme that is thought-provoking and challenging. Prof John Hunt and his colleagues have welcome us to Liverpool with a clear message that makes us thinking about the past while looking towards an ambitious future. The choice of the plenary and keynote speakers will bring on stage some of the best scientists of our generation. The translation day will help us assess the socio-economical impact of our innovation. Through presentations, chairing of sessions and their independently-organised workshops, the Young Scientist Forum will promote new ways of thinking and communicating.

I look forward to all this with great excitement and optimism. I congratulate Prof John Hunt for choosing such a fantastic venue and for structuring such a diversified programme. On behalf of the whole ESB Council I express my deepest gratitude to him and to his team for their kind hospitality and social programme.

Finally, I wish you all a great time in Liverpool where you will see old friends and meet new ones; a time when you will inspire and be inspired, a time of excitement for your research, and a time of new hopes for our patients.

ESB President: Matteo Santin

Book Signings at ESB2014

Professor David Williams

Essential Biomaterials Science

The latest book written by Professor David Williams, has just been published. You can meet the author and examine display copies of *Essential Biomaterials Science* in the coffee and lunch breaks after his talk on Monday 1st September in the exhibition / poster area of Hall 2 stand 142. The book is available from the publisher Cambridge University Press, www.cambridge.org, ISBN 9780521899086.

Copies purchased from the publisher and brought to conference may be signed by Professor Williams.

Please click on the image to the left to download a 20% discount coupon. Print out the coupon and bring it with you to the conference to receive a 20% discount.

Professor Larry Hench

Boing Boing the Bionic Cat

The award-winning *Boing-Boing the Bionic Cat* series of children's books written by Professor Larry Hench will be available for purchase and signing by the author during the meeting. Professor Hench will be in attendance at the stand on 2/9/14 from 11:00-14:00 for a dedicated session of book signing. You can meet the author and examine display copies in the coffee and lunch breaks in the exhibition / poster area of Hall 2 stand 64. A limited number of books will be brought to the conference (and the publisher will only be able to accept cash or cheques) but you may guarantee books at a special delegate rate by pre-ordering (credit cards accepted) from the publisher here: <http://www.canofwormsenterprises.co.uk/goldaward>

Online orders will be available to pick up and be signed by Professor Hench at the conference.

Conference Information

Venue

The Liverpool ESB2014 Conference will be hosted at ACC Liverpool, which combines the Liverpool Echo Arena and BT Convention Centre. ACC Liverpool is a unique facility – the only interlinking arena and convention centre complex under one roof in Europe. The Convention Centre and Arena stand in an iconic building on Liverpool's world famous Mersey waterfront, next to the Grade I listed Albert Dock, home to Tate Liverpool, the Beatles Story and numerous bars and restaurants. The address of the venue is:

BT Convention Centre (within ACC, Liverpool)
Kings Dock
Liverpool Waterfront
L3 4FP
Tel: +44 (0)151-475 8888

Registration

Registration will take place in the BT convention centre galleria Saturday-Wednesday. The registration desk will open:

Saturday August 30 th	14:00 - 18:00	<i>The Speaker Preview Room will be open from 13:00</i>
Sunday August 31 st	07:30 - 19:00	
Monday September 1 st	07:30 - 19:30	
Tuesday September 2 nd	07:30 - 18:30	
Wednesday September 3 rd	07:30 - 17:00	

Poster Sessions

Poster sessions will take place during lunch breaks 12:30-13:30 in addition to a designated poster viewing between 18:00-19:30 on Monday 1st September; presenters are encouraged to stand by their posters during these times. Recommended poster size is A0 (90cmx120cm) in portrait format. If you would like to take your poster away please remove it before the beginning of the closing ceremony. Poster boards will be numbered, please refer to the abstract book for the location of your poster board.

Podium Presentations

Presentation format for standard oral presentations is 12 minutes plus 3 minutes to respond to questions, which will be strictly controlled by the session chair(s). Speakers are asked to upload their presentations in the speaker preview room (Room 7) at least half a day prior to their scheduled talk. The use of personal computers to display talks in the presentation rooms is not permitted.

Rapid Fire Presentations

Rapid Fire Presentations will take place in Hall 2. Timings will be strictly controlled to a 90 second presentation and 30 seconds to address a single question, there is no maximum slide limit. Presentations must be uploaded in the speaker preview room (Room 7) at least half a day prior to your allocated slot, and use of personal laptops is not permitted.

Wi-Fi

Free Wi-Fi is provided throughout the conference venue, a password is not required. The Wireless Network Connection name is *Free_Wifi*

Travel

The ESB2014 team has coordinated a number of discounted travel options for its delegates which should be [booked through the travel section of the ESB2014 website](#).

Taxi: We have negotiated a discounted rate with INTX Liverpool Executive Chauffeur Service, from £20 per journey for a single passenger from Liverpool Airport. You can book and pay for transfers to and from both Liverpool and Manchester Airports online.

Coach: We have organized free coach transfers from Manchester and Liverpool airports on 30th August and 3rd September to the BT Convention Centre. For the 30th August, coaches will leave each airport on the hour starting at 12pm with the last one leaving at 7pm. For the return journey on the 3rd September, coaches will leave the BT Convention Centre hourly starting at 4pm with the last one leaving at 7pm. Delegates wishing to use this free service need to book by following the instructions online.

Train: We have negotiated a fare reduction of 20% on Virgin Trains advance fares in standard and first class from London to Liverpool for delegates, but these must be booked through the ESB2014 website using the password *Bio2014* which is case-sensitive.

If you have been unable to take advantage of these travel options, getting to the venue is straight forward.

From Liverpool John Lennon Airport

Bus: Bus stops are located on Speke Hall Avenue which is a short walk from the airport exit. Take bus numbers 82A or 500 and disembark at Liverpool Albert Dock, both routes have an approximate journey time of 30 minutes. The convention centre is approximately a 5 minute walk from here.

Taxi: There is a taxi rank located immediately outside the airport exit. A taxi into Liverpool city centre or the convention centre directly will take around 20 minutes.

From Manchester Airport

Train: Trains from Manchester Airport train station depart to Liverpool Lime Street station approximately every 30 minutes, with a journey time of around 1 hour. From Liverpool Lime Street station the convention centre is around a 20 minute walk across the city centre.

Taxi: There are several taxi ranks throughout Manchester airport. A taxi into Liverpool city centre or the convention centre directly will take around 45 minutes.

Travel to the venue by car

From the North: Leave the M6 at junction 26 and follow signs for M58 Liverpool. Follow to end of M58 and then take signs for A59 Liverpool. Continue to follow Liverpool City Centre until picking up signs for the Albert Dock. BT Convention Centre's car park is signposted Waterfront on the city wide 'available spaces' signage.

From the South: Leave the M6 at junction 21A and take the M62 to Liverpool. At the end of the M62 follow signs for Liverpool City Centre along Edge Lane, following signs for the Albert Dock.

For Sat Nav users, please use the postcode L3 4BX or enter the city as 'Liverpool' and the road name as 'Queen's Wharf'.

Parking

For conference parking, please use the multi-storey car park directly adjacent to the conference centre (£10 per 24 hours).

Prizes

The Four Best Student Oral Presentations

Winners will be notified during the closing ceremony and receive €200 and a certificate. The candidate must be a student (with a letter from their supervisor), be the presenting author of the presentation and must have had an abstract that was accepted during the official abstract submission process. The candidate should indicate on the registration form if they wish to be considered for the award. Prizes will be awarded during the closing ceremony.

The Four Best Student Poster Presentations

Winners will be notified during the closing ceremony and receive €150 and a certificate. The candidate must be a student (with a letter from their supervisor), be the presenting author of the presentation and must have had an abstract that was accepted during the official abstract submission process. The candidate should indicate on the registration form if they wish to be considered for the award. Prizes will be awarded during the closing ceremony.

Certificates of Attendance

Certificates of attendance can be provided after the event at the delegate's request. If you would like a certificate of attendance please email the conference secretary by 30th September 2014 and your certificate will be sent to you by email, or request one at the registration desk.

Social Programme

Welcome Reception - Open to All Delegates and Exhibitors

Sunday 31st August, 18:30-20:30, BT Convention Centre

The welcome reception will take place at the convention centre after the first day of exciting scientific sessions; attendance is included in your registration fee.

YSF Hard Days Night Social Event - Ticket Only

Sunday 31st August, 19:30-late, Liverpool ONE Bridewell

The YSF will be hosting a social event at Liverpool ONE Bridewell, formerly a prison; this venue is situated in the heart of Liverpool's city centre and a short walk from the nightlife of Liverpool's famous Mathew Street and Concert Square. Tickets for this event can be purchased online during registration and will include food, drinks and live music, but be quick as tickets are limited.

Chairpersons Dinner - Invitation Only

Monday 1st September, 19:30-22:00, Liverpool Tate Gallery

The chairperson's dinner will be held at the Liverpool Tate Gallery, one of the most important collections of Modern Art in Europe, located at Liverpool's historic Albert Dock.

Gala Dinner - Ticket Only

Tuesday 2nd September, 19:30 reception for 20:00 dinner, Convention Centre

The ESB2014 gala dinner will be at the convention centre. Tickets can be purchased during registration. If you have not purchased a ticket online but would like to attend the gala dinner, please speak to one of the local organising committee at the registration desks.

Food and Drink during the conference

The conference registration fee includes morning coffee breaks, a hot fork buffet lunch and traditional afternoon tea during the conference.

Excursions / Accompanying Person Trips

Liverpool Football Club open top bus tour

Take an open top bus tour to Anfield stadium, home of the famous Liverpool Football Club via a narrated tour of some of Liverpool's historic landmarks. Tours depart from the Pump House entrance to the Albert Dock, 5 minutes walk from the conference centre. For more information visit the ESB2014 website.

The Beatles Story Museum

Located in the Albert Dock Complex the Beatles Story Museum tells the story of the worlds original Boy band! A discount voucher of 20% has been negotiated for every ESB delegate which are available by request.

Walking Tours of Liverpool

Interested in the cultural history of Liverpool? Then you can go on one of two walking tours: the Bluecoat cultural walk, and the Bluecoat literary walk. Or possibly visit the Tate Art Gallery at Albert Dock. Click the image to the right for further details.

Awards

George Winter Award – Sunday 31st August, 09:00

Guy Daculsi, *University of Nantes*: Biography on page 20

The ESB Council will choose an International Scientist who has contributed significantly to the knowledge in the field of biomaterials and/or the material controlled or influenced reactions within the host body through basic, experimental and/or clinical research. The work concerned and the results must have been published. This award is established to recognise, encourage and stimulate outstanding research contributions to the field of biomaterials and is presented annually during the Biomaterials conference of the Society, and consists of a certificate, a plaque and a refund of the registration fee and travelling expenses to the conference.

Jean Leray Award – Sunday 31st August, 17:30

Lorenzo Moroni, *University of Twente*: Biography on page 21

This award is established to recognize, encourage and stimulate outstanding research contributions to the field of biomaterials by young scientists. It will be presented annually during the Biomaterials conference of the Society, and consists of a certificate, a plaque, a refund of the registration fee and travelling expenses to the conference and a cash prize. The nominee should not be older than 40 years at the close of nomination and should be not more than 8 years post-doctoral. Furthermore, the nominee must have contributed to the knowledge in the field of biomaterials and/or the material controlled or influenced reactions within the host body through basic, experimental and/or clinical research. The nominee needs neither to be a member of the European Society for Biomaterials nor a citizen of a European country.

International Award – Wednesday 3rd September, 13:30

James Anderson, *Case Western Reserve University, Cleveland, Ohio*: Biography on page 22

The International Award is a prestigious recognition by the ESB of scientists who have generally spent their career outside Europe, who have a widely recognised, high scientific profile, and have made major contributions to the field of biomaterials. The awardee will have shown strong evidence of collaborations with members of our scientific community in Europe throughout their career.

Plenary Speaker Biographies

David Williams

Wake Forest Institute of Regenerative Medicine

Monday 1st September, 08:00 – 09:00, Hall 1

Professor Williams has had 45 years' experience in the science of biomaterials, medical devices and tissue engineering. During his career he has published over 30 books and 400 papers; his latest book, *Essential Biomaterials Science* will be published by Cambridge University Press in June 2014. He has been Editor-in-Chief of *Biomaterials*, the world's leading journal in this field since 2000. He has received the major awards from the US, European and Indian Societies of Biomaterials including the Founders Award of the US Society for Biomaterials in 2007, and he received the prestigious *Acta Biomaterialia* Gold Medal in 2012. In 1999 he was elected as a Fellow of the Royal Academy of Engineering in recognition of his contributions to Engineering in Medicine. He is currently global President of the Tissue Engineering & Regenerative Medicine International Society (TERMIS).

Professor Williams left the University of Liverpool, UK, in 2007, where he had been Head of Clinical Engineering, Director of the UK Centre for Tissue Engineering and Pro Vice Chancellor. While retaining the title of Emeritus Professor at Liverpool, he is currently Professor and Director of International Affairs, Wake Forest Institute of Regenerative Medicine, North Carolina, USA. In addition, he is a Visiting Professor in the Christiaan Barnard Department of Cardiothoracic Surgery, Cape Town, South Africa, a visiting Professorial Fellow at the Graduate School of Biomedical Engineering, University of New South Wales, Australia, a guest professor at Tsinghua University, Beijing, and Advisory Professor at Shanghai Jiao Tong University, China and the National University of Singapore. He is Visiting Chair Professor of Biomedical Materials, Taipei Medical University, Taiwan, and a Visiting Professor at Sree Chitra Tirunal Institute for Medical Sciences and Technology, Thiruvananthapuram, India. In Cape Town, with Professor Peter Zilla, the current Christiaan Barnard Professor of Surgery, he has formed a company that will produce low cost high technology medical devices that can be used with minimally invasive procedures to treat young adults in sub-Saharan Africa, who currently have no therapies available.

Stephen Minger

GE Healthcare

Monday 1st September, 14:30 – 15:30, Hall 1

Stephen received his PhD in Pathology (Neurosciences) in 1992 from the Albert Einstein College of Medicine in New York City. After post-doctoral work in CNS gene therapy, neural transplantation and neural stem cell biology at UCSD with Professor Fred “Rusty” Gage, he was appointed a Lecturer in Biomolecular Sciences at King’s College London in 1998., Senior Lecturer in Stem Cell Biology in 2005 and was Director of the Stem Cell Biology Laboratory from 2002 until joining GE in 2009.

Over the past 20 years, Stephen’s research group has been at the forefront of human stem cell research. In 2002, together with Professor Peter Braude and Dr Susan Pickering, his team was awarded one of the first two licenses granted by the UK Human

Fertilisation and Embryology Authority for the derivation of human embryonic stem cells and his group was the first to deposit a human ES cell line into the UK Stem Cell Bank. Stephen was also one of the first two groups in the UK to be granted a research license by the HFEA in 2008 to pursue Somatic Cell Nuclear Transfer to generate “hybrid human embryos” for research into genetic forms of neurodegenerative conditions. He was actively involved with the UK Department of Health and with the Minister for Public Health in the consultation with both Houses of Parliament that led to the passage of the Human Embryo Bill of 2009 and the inclusion of new forms of animal-human embryos within primary legislation.

Stephen was the Stem Cell Expert and a Member of the UK Gene Therapy Advisory Committee at the Department of Health from 2006-2012 and was the Focal Point for Regenerative Medicine, Drug Discovery and Modernisation of Traditional Chinese Medicine in China for the UK Department of Business, Innovation and Skills from 2006-2009. He has also been a an external consultant and reviewer to the European Commission Framework Programs since 2003, a member of the Grants Working Group of the California Institute of Regenerative Medicine since 2004, and is a member of the Board of Directors of the Canadian Centre for the Commercialisation of Regenerative Medicine.

In the summer of 2013, Stephen was appointed Chief Scientist for Cellular Sciences, GE Healthcare Life Sciences, and is now responsible for long-term global research strategy for technology development in cell therapy, regenerative medicine, cellular technologies, *in vivo* diagnostic imaging and molecular pathology/personalised medicine.

Dietmar Hutmacher

Queensland University of Technology

Tuesday 2nd September, 08:00 – 09:00, Hall 1

Professor Dietmar W. Hutmacher is the Chair of Regenerative Medicine at the Institute of Health and Biomedical Innovation of Queensland University of Technology, where he leads the Regenerative Medicine Group, a multidisciplinary team of researchers including engineers, cell & molecular biologists, polymer chemists, material scientists, clinician scientists, and veterinary surgeons. Prof Hutmacher has extensive expertise in bioengineering, tissue engineering and regenerative medicine and more recently he was not only among the pioneers but also developed outstanding track record in two new cutting edge research areas namely “in vitro disease models” and “development of humanized mice models via the translation of tissue engineering platform technologies”. Currently, this work in the Hutmacher laboratory has a focus on cancer research.

Prof Hutmacher’s international standing and impact on the field are illustrated by his publication record (more than 240 journal articles, edited 10 books, 30 book chapters and more than 450 conference papers) and citation record (more than 12,000 citations, h-index 54).

Awards and funding: In 2011, Prof Hutmacher was awarded the prestigious Australian Research Council Future Fellowship and in 2012 he was elected to join the highly esteemed International College of Fellows Biomaterials Science and Engineering, and received the Australasian Society for Biomaterials and Tissue Engineering (ASBTE) for Research Excellence Award. In 2012 he was elected by his peers to become one of the 23 founding members of the International Fellows of Tissue Engineering and Regenerative Medicine Society. This group provides leadership and vision for the Society with more than 3000 members. He holds since 2006 an Adjunct Professorship at the Georgia Institute of Technology (GTECH) and he was awarded in 2011 the highly prestigious Hans Fischer senior Fellowship at the Technical University Munich (TUM). Over the past 15 years in academia, Prof Hutmacher has been a lead Investigator, co-investigator or collaborator in grants totalling more than AUD 50 million, including support from the National Institutes of Health – USA, Australian Research Council, National Health and Medical Research Council – Australia, European Union, DFG, and philanthropic and industry support.

Molly Shoichet

University of Toronto

Tuesday 2nd September, 13:30 – 14:30, Hall 1

Dr. Molly Shoichet holds the Tier 1 Canada Research Chair in Tissue Engineering and is Professor of Chemical Engineering & Applied Chemistry, Chemistry and Biomaterials & Biomedical Engineering at the University of Toronto. She is an expert in the study of Polymers for Drug Delivery & Regeneration which are materials that promote healing in the body. Dr. Shoichet has published over 450 papers, patents and abstracts and has given over 275 lectures worldwide. She currently leads a laboratory of 25 researchers and has graduated 115 researchers over the past 18 years. She founded two spin-off companies from research in her laboratory and is actively engaged in translational research.

Dr. Shoichet is the only person to be a Fellow of Canada's 3 National Academies: the Canadian Academy of Sciences of the Royal Society of Canada, the Canadian Academy of Engineering, and the Canadian Academy of Health Sciences. She is the recipient of many prestigious distinctions including: the Canada Council for the Arts' Killam Research Fellowship, NSERC's Steacie Fellowship, CIAR's Young Explorer's Award (to the top 20 scientists under 40 in Canada), Canada's Top 40 under 40TM, the Society for Biomaterials' Clemonson Award, and International Fellows of Tissue Engineering and Regenerative Medicine. In 2011, Dr. Shoichet was appointed to the Order of Ontario, Ontario's highest honour, and recognized as a Fellow of the American Association for the Advancement of Science.

In 2013, Dr. Shoichet's contributions to Canada's innovation agenda and the advancement of knowledge were recognized with the QEII Diamond Jubilee Award. Before being recruited to the University of Toronto in 1995, Dr. Shoichet worked at CytoTherapeutics Inc. on encapsulated cell therapy. Dr. Shoichet received her S.B. from the Massachusetts Institute of Technology in Chemistry (1987) and her Ph.D. from the University of Massachusetts, Amherst in Polymer Science and Engineering (1992).

Larry Hench

Florida Institute of Technology College of Engineering

Wednesday 3rd September, 08:00 – 09:00, Hall 1

Larry Hench, University Professor of Biomedical Engineering in the Florida Institute of Technology College of Engineering, has been awarded the highly acclaimed international 2014 Acta Biomaterialia Gold Medal Award. The award recognizes excellence in research and development in the field of biomaterials. Professor Hench, who is also director of the Florida Tech Center for Medical Materials and Photonics, specializes in bio-ceramics and is a member of the National Academy of Engineering (NAE).

Born in Ohio in 1938, Dr. Hench received his bachelor's degree in 1961 and doctoral degree in 1964 in ceramic engineering from The Ohio State University. After 32 years on the faculty, Hench retired from the University of Florida as Emeritus Professor to join Imperial College, University of London, as chair of ceramic materials. There, he co-founded and co-directed the Tissue Engineering and Regenerative Medicine Centre for 10 years.

Discoveries made by Hench and his colleagues in the 1980s and 1990s have resulted in numerous Federal Drug Administration (FDA) approvals. In the mid-'80s the FDA approved the use of bioactive glass devices to reconstruct the ossicular chain (part of the middle ear) and restore hearing. A subsequent FDA approval led to bioactive glass implants to replace teeth, maintain jaw stability and repair maxillo-facial bone defects. In the '90s the FDA approved the use of a particulate form of bioactive glass that led to regenerating new bone to repair bone defects caused by periodontal disease. Numerous FDA approved applications in orthopedic surgery include repair of bone defects following revision surgery of failed hip and knee prostheses, and spinal repair.

Larry Hench, who has dedicated more than 45 years to his work, has earned many international awards, published 800 research papers, 30 books and has 32 U.S. patents. Twelve companies have been founded based upon technology created in Hench's laboratories and the commercial products have led to numerous advanced technology awards. He is also an author of a series of children's books featuring Boing-Boing the Bionic Cat and educational materials such as workbooks, experiment books and hands-on kits to stimulate interest in science, engineering, technology and mathematics (STEM).

Following the plenary lecture, Larry will be awarded with the *Acta Biomaterialia Gold Medal*. Click on the image to the right for further details

Sunday 31st August, 09:00 – 09:30, Hall 1

Professor Daculsi is Director of Research class Exceptional at INSERM, National Institute for Medical Research and Director of the SC3M Electron Microscopic, Microimaging and Microcharacterization Center of Nantes University. His work has mainly focused on the process of mineralization and developing models for the mineral phase of calcified tissues.

In 1984, Guy Daculsi made a thematic change to Biomaterials, and particularly Bioceramics. He directed research on calcium phosphate synthesis to model mineralization, but also to develop substitute materials for calcified tissues, particularly calcium phosphate. He was a pioneer in this field in France, developing an original concept of artificial bone; the Biphasic Calcium Phosphate Concept.

In 1989, Guy Daculsi created the Nantes University Research Centre on Calcified Tissues and Biomaterials. The activity of the laboratory was supported by INSERM and the CNRS. After 16 years of management of the research center for Materials of Biological Interest, the laboratory became UMR INSERM U791, Laboratory Osteoarticular and Dental Tissue Engineering.

He developed a theme of original research relevant to the physio-pathology of calcified tissues at the level of mineral phases, particularly degradation and dissolution by specialized cells. These studies and models are associated with design, development and study of mineral phases used as synthetic bone and dental substitutes.

His International contributions to Bioceramics and Bone substitutes has been recognized at a major scientific distinction IUSBSE (International Union of Societies for Biomaterials Science and Engineering) of the 8th World Congress on Biomaterials in 2008.

During the World Biomaterials Congress in 2008, he was awarded Fellow of the world federation of Biomaterials scientific societies (Fellow in Biomaterials Science and Engineering, FBSE). Guy Daculsi served on the executive Board of ESB, before being Chair of the 20th ESB in 2006.

Sunday 31st August, 17:30 – 18:00, Hall 1

Dr Moroni studied Biomedical Engineering at the Polytechnic University of Milan, Italy, and Nanoscale Sciences at Chalmers Technical University, Sweden. In 2001, he visited the lab of Professor Luke Lee at University of California Berkley, where he worked on microfabrication technologies for tissue engineering applications. He received his Ph.D. (cum laude) in 2006 at University of Twente on 3D scaffolds for cartilage and osteochondral regeneration, for which he was awarded the European doctorate award in Biomaterials and Tissue Engineering from the European Society of Biomaterials (ESB). In 2007, he worked at Johns Hopkins University as a post-doctoral fellow in the Elisseeff lab, focusing on hydrogels and stem cells. In 2008, he was appointed the R&D director of the Musculoskeletal Tissue Bank of Rizzoli Orthopedic Institute in Bologna, Italy, where he investigated the use of stem cells from alternative sources for cell banking, and the development of novel bioactive scaffolds for bone and cartilage regeneration.

From 2009 till 2014, he joined again the University of Twente, where he worked as an assistant professor until 2013 and as an associate professor thereafter in the Tissue Regeneration department within the MIRA institute for Biomedical Technology and Technical Medicine. Since 2014, he holds an associate professor position at the MERLN Institute for Technology Inspired Regenerative Medicine of Maastricht University. His research group interests aim at developing new biofabrication technologies to generate libraries of 3D scaffolds able to control cell fate. Since 2012, he has been a board member of the Young Scientist Forum of the ESB and co-chairman of the “Biofabrication” thematic group within the Tissue Engineering and Regenerative Medicine Society. In 2013, he was also elected to the editorial board of the journal “Biofabrication”. He is also a co-founder of the biotech company Screvo B.V., which is committed to the production of animal implantable 3D high through-put screening systems.

Wednesday 2nd September, 13:30 – 14:30, Hall 1

Dr. Anderson is a Distinguished University Professor and Professor of Pathology, Macromolecular Science and Engineering, and Biomedical Engineering at Case Western Reserve University. In addition, he is a practicing pathologist in the Department of Pathology, University Hospitals Case Medical Center.

James M. Anderson received his Ph.D. at Oregon State University in 1967, his M.D. degree from the Case Western Reserve University School of Medicine in 1976, and did his Anatomic Pathology residency at the Institute of Pathology of University Hospitals of Cleveland. Following the completion of his residency, he joined the faculty of the Institute of Pathology at Case Western Reserve University. Throughout his career James Anderson has received many honors and awards such as a NIH MERIT Award, the Elsevier

Biomaterials Gold Medal Award, the Honoris Causa Degree by the University of Geneva and the 2013 Acta Biomaterialia Gold Medal, amongst others.

He is a founding member of the Society for Biomaterials and the Controlled Release Society and serves as a consultant to the NIH, FDA, and ISO, and is an elected member of the Institute of Medicine National Academy and the National Academy of Engineering. He is the Editor-in-Chief of the Journal of Biomedical Materials Research-Part A. Dr. Anderson has worked in the area of biomaterials, medical devices, and prostheses for the past 40 years and his current activities range from the clinical pathology evaluation of retrieved implants from humans to fundamental studies of cellular interactions with biomaterials.

Symposia

The ESB 2014 Conference will feature a number of symposia:

- YSF Entrepreneurship Workshop
- Fellows of Biomaterials
- Antimicrobials, Biofilms & Surfaces
- The Meaning of Surface Charge for Biomaterial Characterization
- European Orthopaedic Research Society (EORS)
- Translational Research
- UK Society for Biomaterials (UKSB) Annual Meeting
- Women in Science & Engineering
- Advances in Bioactive Glasses

These symposia will run alongside the normal scientific session and are open to every delegate of the ESB 2014 conference. No prior registration is necessary.

YSF Entrepreneurship Workshop

Entrepreneurship – an Academic and Industrial Perspective

31st August 2014, 13.30 – 16.00

Symposium Organizers: Lorenzo Moroni (University of Twente), Sandra Van Vlierberghe (University of Gent), Anna Wistrand (KTH Royal Institute of Technology)

The workshop will give a flavour of what it takes to create spin-off companies from innovative research activities that take place at Universities, as well as in Industry. Talks will span from personal experiences in facing the challenges of setting up a spin-off, to the availability of educational programmes and important points to consider when applying for patents.

The afternoon has an extensive spectrum of experienced experts in entrepreneurship. Invited speakers include:

- Dirk Grijpma (University of Twente)
- Dietmar Hutmacher (Queensland University of Technology and Technical University of Munchen)
- Jens Thies (DSM, The Netherlands)
- Chris Sutcliffe (University of Liverpool)
- Alex Sim (AMSBIO Ltd)
- Chris Unsworth (Business Gateway, University of Liverpool)

Dirk Grijpma

Dirk Grijpma is Professor in Biomaterials Science and Technology at the University of Twente. He also holds a part-time position at the University Medical Center Groningen. His expertise is in the synthesis and properties of resorbable polymeric materials for use in medical devices, tissue engineering and in the delivery of relevant biological compounds, and the interaction of these materials and devices with cells and tissues.

Current research includes the development of advanced microstructures by photo-polymerization of functionalized degradable oligomers in stereolithography and research programmes on the tissue engineering of cardiac muscle and blood vessels, and the synthesis and processing of composite materials for fracture reconstruction in maxillofacial surgery.

Pre-designed anisotropic architectures based on biologically active materials are being developed to engineer musculoskeletal and cardiovascular tissues in bioreactors under conditions that mimic the natural environment. His research includes the synthesis and characterization of large arrays of materials and their evaluation by high-throughput methods, which will likely lead to the discovery of novel materials that perform unexpectedly well in their interaction with cells and tissues.

His research interests are: resorbable polymers for medical applications, structure-property relationships in polymers, tissue engineering, bioreactor technology, drug delivery, ring opening polymerization, photo-polymerization and stereolithography. He is author of more than 180 scientific publications and holds 13 patents. He is editorial board member of Biomaterials, Acta Biomaterialia and of the Journal for Applied Biomaterials and Biomechanics. Prof. Grijpma co-founded Medisse (www.medisse.com), a company developing medical implants based on poly(trimethylene carbonate). Medisse's lead product is FlexiSurge® Adhesion Barrier, a resorbable membrane that prevents the occurrence of postoperative adhesions. He was elected Fellow Biomaterials Science and Engineering (FBSE) in 2008.

Dietmar Hutmacher

Professor Dietmar W. Hutmacher is the Chair of Regenerative Medicine at the Institute of Health and Biomedical Innovation of Queensland University of Technology, where he leads the Regenerative Medicine Group, a multidisciplinary team of researchers including engineers, cell & molecular biologists, polymer chemists, material scientists, clinician scientists, and veterinary surgeons. Prof Hutmacher has extensive expertise in bioengineering, tissue engineering and regenerative medicine and more recently he was not only among the pioneers but also developed outstanding track record in two new cutting edge research areas namely "in vitro disease models" and "development of humanized mice models via the translation of tissue engineering platform technologies". Currently, this work in the Hutmacher laboratory has a focus on cancer research

Prof Hutmacher's international standing and impact on the field are illustrated by his publication record (more than 240 journal articles, edited 10 books, 30 book chapters and more than 450 conference papers) and citation record (more than 12,000 citations, h-index 54).

Awards and funding: In 2011, Prof Hutmacher was awarded the prestigious Australian Research Council Future Fellowship and in 2012 he was elected to join the highly esteemed International College of Fellows Biomaterials Science and Engineering, and received the Australasian Society for Biomaterials and Tissue Engineering (ASBTE) for Research Excellence Award. In 2012 he was elected by his peers to become one of the 23 founding members of the International Fellows of Tissue Engineering and Regenerative Medicine Society. This group provides leadership and vision for the Society with more than 3000 members. He holds since 2006 an Adjunct Professorship at the Georgia Institute of Technology (GTECH) and he was awarded in 2011 the highly prestigious Hans Fischer senior Fellowship at the Technical University Munich (TUM). Over the past 15 years in academia, Prof Hutmacher has been a lead Investigator, co-investigator or collaborator in grants totalling more than AUD 50 million, including support from the National Institutes of Health – USA, Australian Research Council, National Health and Medical Research Council – Australia, European Union, DFG, and philanthropic and industry support.

Jens Thies

Jens Thies received his PhD from Heriot Watt University in Edinburgh, under the supervision of Professor Ian Cowie, in 1998. Subsequently he undertook a post-doctoral position at DSM Research in the field of Rotaxanes. In 2000 he joined David Tirrell's groups at Caltech as a visiting post-doctoral researcher, investigating recombinant protein engineering. He then joined DSM Research and initiated the functional coating platform, launching several products mainly in DSM's Advanced Surface and Medical Coatings businesses. He is currently responsible for Research, Technology and Development of DSM Biomedical's Drug Delivery business globally. Jens also holds an Executive Masters in Business Innovation from TiasNimbas Business School.

Chris Sutcliffe

Dr Chris Sutcliffe is widely acknowledged as one of the world's leading research academics in additive layer manufacturing. He has been associated with flexible manufacturing methods since 1999 when he joined the Department of Manufacturing Engineering at the University of Liverpool. Here, along with academic colleagues he was a founder member of the original EPSRC-funded IMRC working in a range of fields including laser-processing using short pulse duration lasers, cold gas dynamic manufacturing, stereolithography of anatomical phantoms, selective laser sintering of medical devices, the production of controlled release oral dosages and selective laser melting.

He is now recognised as an expert in the field of selective laser melting; in particular, in the design of production manufacturing equipment and the development of next generation orthopaedic, trauma, spine and CMF implants for which he holds base technology and device design patents which have been licensed internationally. As an academic, he has been an investigator on 34 manufacturing research projects, 17 as PI totalling over £11 M in funding. He has extensive industrial experience including being R&D Director at MTT Technologies where he was, prior to its 2011 purchase by Renishaw, responsible for the delivery of a £2.5m portfolio of EU, TSB, EPSRC and company-funded projects. Dr Sutcliffe therefore has considerable experience in the management and delivery of large scale, multi-partner, multi-disciplinary research projects. He has worked with other universities, and has experience of leading and managing collaborative projects with partners such as Heriot Watt, Cambridge, Manchester, Cranfield, Nottingham, Bath, Edinburgh, Sheffield, Cambridge and Glyndwr Universities.

Dr Sutcliffe has built a research group at the University of Liverpool with a strong international reputation in manufacturing particularly in the development of orthopaedic devices in close collaboration with industrial partners. Dr Sutcliffe plays a strong role in the development of the academic activities of the School of Engineering playing a leading role in the development of manufacturing teaching, learning and design.

Alex Sim

Alex Sim is the Founder and CEO of AMS Biotechnology (Europe) Ltd. Alex, graduated from Strathclyde University as a Molecular Biologist prior to completing a postgraduate degree in Marketing. He has been involved in translating cutting edge life science technology into successful revenue generating products for 30 years. With Amersham International (now GE) he led the team that developed Hybond and was involved in the commercialisation of multiple technologies that have had direct impact on genomics and proteomics.

In 1988, Alex founded AMS Biotechnology (AMSBIO). Since then he has raised venture funding, sold a variety of companies and continues to contribute to the success of small innovative SMEs. AMSBIO provides specialist biotools including tissues, stem cells, and cell based assays in addition to tailored screening services that are increasingly being performed as 3D assays. Very recent initiatives include the establishment of new laboratories in Biocity near Glasgow and the opening of the company's North American headquarters in Cambridge, Massachusetts, where Alex now spends much of his time.

Chris Unsworth

Chris was appointed IP Manager at the University of Liverpool in January 2011 where he is responsible for the exploitation of the University's IP. Over the period since 2011 Chris developed and implemented many of the new structures and procedures that now comprise Liverpool IP. Chris also manages all relationships with the University's licensees and spin-out companies.

Chris first came to the University in 2006 to run NeoCare Ltd a spin-out created to exploit chromatic algorithm patents developed in the University's engineering department. Following his exit from NeoCare Chris held a succession of roles managing; the University's POC fund, a £1.3m TSB project with Unilever in the field of high shear mixing, the establishment and operation of the £2.8m Knowledge Centre for Material Chemistry before being appointed as the Business Manager for Science in 2010.

Chris has a background in industrial management. Following a first degree in Chemistry and Fuel Technology he worked for the National Coal Board for five years as Fuel Technologist. In 1986 Chris graduated with an MBA from Manchester Business School from where he joined Dorman Smith Switchgear as Business Development Manager. Over the next twenty years he held a variety of positions as Managing Director in operating companies run by groups such as BICC, GEC Alsthom, Hanson Electrical and Scholes.

Fellows of Biomaterials Symposium

The Race Between Engineering and Biology in Replacing Human Tissues

31st August 2014, 13.30 – 16.00

Symposium Chair: Joachim Kohn, Rutgers University

The chair will define this challenge, a take vote of the audience. There will then be six 15 minute talks from a panel of current FBSE fellows:

- **Barbara Boyan**
- **Rui Reis**
- **Abhay Pandit**
- **Cristina Tanzi**
- **John Kao**
- **David Williams**

who will expound, sometimes controversially, their own points of view about the challenge. Following the talks there will be a Q & A session and finally a vote of the audience.

This symposium is open to all conference delegates.

Translational Research Symposium

Progressing Innovations from the Bench to Bedside

2nd September 2014, 09:00 – 18:00

Symposium Organizers: Yves Bayon, Marc Bohner, David Eglin & Paul-Henri Vallotton

The path leading to commercialization – from promise to actual delivery, from prototype to useful product – is scattered with great challenges and hurdles:

- **Financing**
- **Intellectual property** (*i.e.* patentability, freedom to operate)
- **Legal agreements** with partners and services/research contractors
- **Regulatory environment** driven by FDA, CE mark – notified bodies, EMEA...
- **Manufacturing process** and its validation
- **Clinical trial design**
- **Relationships with national/regional healthcare authorities**
- **Healthcare reimbursement policies.**

On the other hand, the latest generations of biomaterials, are becoming more and more sophisticated, such as combination products and smart materials may face the limitations of standard *in vitro* and *in vivo* evaluation techniques. Regulatory agencies continuously raise the quantity of requested information for any new submitted devices: purity and characterization, safety and performance evaluation, mechanism of action, *etc.* In these respects, academia and industries may increasingly be partners throughout the full cycle of the commercial development of new biomaterial concepts and technologies.

Ideas often start on pieces of paper and a test tube on the basis of basic science research, in academic and institutional laboratories, with the support of public and philanthropic research grants. Talented scientists drive these ideas and projects through various stages of early development that mostly result in significant scientific achievements, illustrated by publications in peer-reviewed journals and, less often, by patent filings.

Many of the new biomaterial concepts and technologies, when carefully evaluated, may have benefit for patients and the public. But this further requires rigorous complementary research development activities to advance new concepts and technologies to the patients and the public: *e.g.* preclinical proof of concept and performance evaluation by *in vivo* animal studies, extensive biocompatibility studies to be performed according to international standards and in GLP (Good Laboratory Practice) conditions, safety and performance evaluation in expensive human clinical trials with appropriate product type (formulation, device *etc.*).

New concepts and technologies are generally percolated to life and progress through the early incubation phase, often showing proof-of-concept and the full promise of potentially innovative products. But, most translational efforts die here and there are multiple financial, scientific and sociological reasons for this phenomenon.

Given the increasing links between academic research and industry globally, the ESB 2014 conference includes this Translational Research Symposium. This will bring together leading Tier one companies in the medical device markets, small and medium enterprises and entrepreneurial

academics who can share their experiences on taking biomaterials technologies to commercial endpoints.

The Symposium will focus on *'Progressing innovations from bench to bedside'*. It will be richly illustrated by testimonies of leading biomaterials & medical device industries, start-up & SME entrepreneurs and academics, in the business exploitation and commercial translation of biomaterial related concepts and ideas, for now and to the 2020+ horizon. The main goal of the programme is to highlight the key factors leading to, or impairing successful translation. Specifically the industry will include three sessions:

- 1) The Industry Translation Process & 2020 Horizon – Invited speakers (*e.g.* DePuy, Covidien).
- 2) Academic management innovation & Academic spin-offs testimonies – Invited speakers and Panel discussion with selected industries, entrepreneurs & academics.
- 3) Forum for sharing translation initiatives – Abstract submission, Q&A with a mixed panel of industrials, entrepreneurs and academics.

This event will be of interest to a wide audience from large medical device producers to academics and entrepreneurs and promoters of biomaterial technologies for medical applications. The programme includes significant time for networking during coffee breaks and lunch. The Symposium feature the following speakers:

- Geoff Richards (AO Research Foundation, Davos);
- Andrea Montali (Depuy Synthes)
- Lars Neumann (Materialise NV, Leuven)
- Philip Procter (Medical Device Industry Consultant)
- Kevin Shakesheff (University of Nottingham and Regentec)
- John Fisher (University of Leeds)
- Michel Thérin (Covidien, Lyon)
- Iain McDougall (Taragenyx, UK)

Lars Neumann

Dr Lars Neumann is a business development manager at Materialise NV, Belgium with specific focus on software for biomedical engineering.

Lars received his doctoral degree in 2012 in Physics from ICFO – The Institute of Photonic Science in Barcelona. His research interests focussed on improving optical imaging techniques for biological systems by custom shaping of laser light fields through the application of nanotechnology. After his doctoral degree, Lars moved to Germany and engaged in the creation and optimisation of R&D project and process management in the automobile industry.

As a physicist curious for new technologies, Lars became interested in additive manufacturing, also known as 3D Printing, and the opportunities that the technology offers especially in biomedical engineering. The human body is one of the most individual systems we can imagine, yet most of our tools and devices are off the shelf and not customised.

At Materialise, Lars focusses on the principle of “Engineering on Anatomy” within the Mimics Innovation Suite and its applications in patient-specific biomedical engineering and science. In his role as business development manager, he is responsible for the academic users of the Mimics Innovation Suite worldwide. Lars is in charge of Materialise’s developing educational programme in Engineering on Anatomy and involved in several European Union funded research projects with academic and industrial partners.

Kevin Shakesheff

Professor Kevin Shakesheff is Director of the UK Regenerative Medicine Platform Hub for Acellular Technologies. His independent scientific career began at the Massachusetts Institute of Technology under a NATO fellowship following a PhD and his qualification as a register pharmacist. His inventions and scientific breakthroughs have resulted in over 170 peer-reviewed full papers that have been cited more than 5500 times to date, the establishment of 2 successful companies, the submission of 13 patent application families and numerous international awards. He currently holds a prestigious European Research Council Advanced Grant within an active research portfolio of more than £7 million.

In addition, he has taken a leading role in shaping interdisciplinary research in the UK through continued membership of senior policy and grant awarding committees. In 1997 he founded, with Dame Julia Polak, the Tissue and Cell Engineering Society (TCES). In 2013 he became a Royal Society Wolfson Merit Award Holder. He is a member of the Medicines and Healthcare Products Regulatory Authority (MHRA) Biologicals and Vaccines Expert Advisory Group, co-Director of the EPSRC Centre for Innovative Manufacturing Centre in Regenerative Medicine, Lead of the Research Councils UK India Science Bridge in Biopharmaceuticals and a Member of the Department of Health’s Modernising Pharmacy Careers Programme. He is a Sub-Panel Member for the UK’s Research Excellence Framework (REF) for 2014. In 2011 he was made a Fellow of the Royal Pharmaceutical Society and in 2013 a Fellow of the Society of Biologists. In 2014 he was selected as one of the 10 most inspirational scientists in the UK by the Engineering and Physical Sciences Research Council (RISE Leader Award).

John Fisher

Professor John Fisher CBE is the deputy Vice Chancellor of the University of Leeds and Director of the Institute of Medical and Biological Engineering.

UK Society for Biomaterial (UKSB) Annual Meeting

2nd-3rd September 2014

Event Chair: Sanjukta Deb, Kings College London

The UK Society for Biomaterials (UKSB) is honoured to be holding its annual meeting as a set of sessions within the ESB meeting. The society is dedicated to nurturing early career and post-doctoral researchers within the UK and providing a platform for dissemination of their research, networking and career progression. At each annual conference in addition to best postgraduate poster and oral presentations, a President's Prize and the Alan Wilson Prize are awarded. The President's Prize aims to recognise outstanding contributions to the UK Biomaterials field, and this year we are delighted to announce that the prize has been awarded to Professor Shelia MacNeil who will be presenting her award lecture in Room 4 on Tuesday 2/9/14 at 09:30. In addition Professor Paul Hatton has been awarded the Alan Wilson prize, which recognises excellent research in the dental biomaterials field, and will be presenting his lecture in Room 4 on Tuesday 2/9/14 at 14:30. The UKSB will also be introducing Dr Manus Biggs who has been selected to receive the Larry Hench Young Investigator Award, which will be presented to him in the Bioactive Glass Symposium in Room 3 on Wednesday 3/9/14 at 14:30, and where he will present his research.

Materials for the Future – University of Liverpool Outreach Event

1st September 2014, 16.00 – 19.30

Event Chair: John Hunt, University of Liverpool

This outreach event will introduce a series of world-expert speakers who will present some of the issues for providing new materials, in a sustainable manner, to meet the needs of an ageing and ever-increasing population. The speakers will provide insight into how new research is providing diverse material solutions such as nano-medicines, stem cell therapies, and high performing next generation medical implants. Delegates will include the ESB 2014 delegation and then also University of Liverpool academics, alumni, industry partners, and civic leaders. The afternoon will showcase world-leading research from the University of Liverpool. The schedule of talks is:

- **Anthony Hollander**, University of Liverpool
- **Steve Rannard**, University of Liverpool
- **Chris Sutcliffe**, University of Liverpool
- **Raphael Levy**, University of Liverpool
- **Stephen Minger**, GE Healthcare
- **Molly Shoichet**, University of Toronto
- **Joachim Kohn**, Rutgers University
- **David Williams**, Wake Forest Institute of Regenerative Medicine

Exhibitors

Anton-Paar – Stand 122

Anton Paar GmbH

Anton-Paar-Str. 20
A-8054 Graz
Austria
Tel: +43 (0) 316 257-0
Fax: +43 (0) 316 257-257
info@anton-paar.com

Anton Paar Ltd

Unit F, The Courtyard
St Albans
AL4 0LA
Tel: +44 (0) 1992 514730
info.gb@anton-paar.com
www.anton-paar.com

Anton Paar produces high-precision measuring and laboratory instruments for industry and research. It is the world leader in the field of Rheometry and in the measurement of Density and Concentration. Other areas of specialty are: Viscometry, Polarimetry, Refractometry, Microwave Sample Preparation & Synthesis, Chemical and Mechanical Surface and Nanostructure Analysis.

IOP Publishing – Stand 1

IOP Publishing

IOP Publishing

Temple Circus
Temple Way
Bristol BS1 6HG
Tel: 0117 929 7481
Email: bmm@iop.org
<http://iopublishing.org>
Representative: Paul MacBeath

IOP Publishing provides a range of journals, magazines, websites, books and services that enable researchers to reach the widest possible audience for their research. Visit our stand at ESB to pick up your free copies of *Biomedical Materials* and *Biofabrication*, read the latest research published in our journals and find out what IOP Publishing can offer to our authors.

Bruker – Stand 148

Bruker UK Ltd

Banner Lane
Coventry
CV4 9GH
Tel: 024 7685 5200
Fax: 024 7646 5317

Sales and service of analytical instrumentation

Scanco Medical – Stand 170

SCANCO MEDICAL

SCANCO Medical

Fabrikweg 2
Bruttisellen 8306
Switzerland
Tel: +41 44 805 9815
Fax: +41 44 805 9801
lfalco@scanco.ch
www.scanco.ch
Representative: Lisa Falco

SCANCO Medical offers a wide range of microCT scanners for specimen and preclinical as well as clinical use (HR-pQCT). These systems are supplied with high-end computing equipment and sophisticated analysis and visualization soft-ware to provide the most comprehensive and industry-leading imaging solutions. SCANCO Medical also offers scanning, analysis and consulting services for a wide range of applications.

BioNavis – Stand 66

BioNavis Oy Ltd
Elopellontie 3C
33470 Ylöjärvi
Finland
Tel: +358 10 271 5030
info@bionavis.com
www.bionavis.com

BioNavis Multi-Parametric Surface Plasmon Resonance (MP-SPR) is a novel approach to the half-a-century old optical SPR phenomenon. SPR has been predominantly used for biomolecular interaction analysis but now MP-SPR broadens the application range also to biophysical studies, such as measurements of absolute refractive indices and formed layer thicknesses, biomaterial studies, such as ceramic and polymer coating characterizations (i.e. CaP, SiO₂, cellulose, polystyrene) as well as biocompatibility studies.

BioPharma – Stand 124

Biopharma Process Systems Ltd

Biopharma House
Winnall Valley Road
Winchester
Hants SO23 0LD
Tel: +44 (0) 1962 841092
www.biopharma.co.uk

The Biopharma Group provides a range of products and services to the pharmaceutical and biotech industries. Our expertise is in freeze-drying and our extensive range means we have equipment suitable for any application. Our dedicated laboratory also offers a range of services in freeze drying including formulation and cycle development.

BOSE-Electroforce – Stand 30

BOSE – ElectroForce Systems Group

Bose Limited, Bose House
Quayside, Chatham Maritime
Chatham, Kent ME4 4QZ
Tel: +44 (0) 3330 142545
Fax: +44 (0) 3330 142501
Electroforce_europe@bose.com
www.bose-electroforce.com

Bose Corporation is a leading supplier of materials testing and durability simulation instruments to research institutions, universities, medical device companies, and engineering companies worldwide. Bose® ElectroForce® test instruments help customers design better products and get them to market faster. Proprietary linear motors developed by Bose are at the heart of ElectroForce instruments, and they provide exceptional performance and energy-efficiency without compromising either.

Bose test instruments provide exceptional dynamic performance and precision for a variety of testing applications, including characterization of engineered materials, soft tissues and biomaterials; biomechanical testing and tissue growth solutions; fatigue testing of components used in industrial and consumer applications; and durability simulation of medical devices, including stents, endovascular grafts, and orthopaedic implants.

Cam Bioceramics – Stand 56

Cam Bioceramics

Zernikedreef 6
Leiden 2333 CL
The Netherlands
Tel: +31 628 740030
Fax: +31 71 524 0650
www.cambioceramics.com
Representative: Ralf-Peter Herber, PhD

Cam Bioceramics is a contract manufacturer of orthobiologic calcium phosphates. Cam Bioceramics develops, engineers and manufactures Orthobiologic Calcium Phosphates to meet our customers' specification. Product range includes: calcium phosphate powders, porous granules, dense granules, shapes or blocks. Cam Bioceramics is ISO13485 certified.

LACTEL® Absorbable Polymers – Stand 2

DURECT Corporation/LACTEL® Absorbable Polymers

PO Box 530, 95014, USA
Tel: 00 1 205.620.0025
Fax: 00 1 408.865.1406
absorbables@direct.com
www.absorbables.com
Representative: John Gibson

At the forefront of biomaterial production is LACTEL® Absorbable Polymers, the first commercial supply of biodegradable polyesters in the U.S. For decades we have supplied GMP excipients for biomaterial use world-wide. At our new, state-of-the-art facility in Birmingham, Alabama we continue to pioneer commercial-scale production of medical-grade polymers.

EBERS Medical Technology SL – Stand 100

EBERS Medical Technology SL

Calle Romero 29, Nave 13
Poligono Empresarium
La Cartuja Baja, Zaragoza, Spain
Tel: +34 876 013826
Fax: +34 876 013826
pmoreo@ebersmedical.com
www.ebersmedical.com
Representative Name: Dr Pedro Moreo

Design, manufacture and commercialization of 3D cell culture and tissue engineering bioreactors, microfluidic devices for cell culture and drug testing and oxygen sensors based on optical technology.

EnvisionTEC – Stand 146

EnvisionTEC GmbH
Brüsseler Str. 51
D-45968 Gladbeck, Germany
Tel: +49-2043-9875-0
Fax: +49-2043-9875-99
info@enviontec.de
www.enviontec.com
Representative: Rüdiger von Bernum

A world leader in Rapid Prototyping and Manufacturing equipment with an expert multi-disciplinary team, EnvisionTEC has produced the most reliable Rapid Prototyping system in the world. With a decade of experience in Tissue Engineering, Envision-TEC's widely accepted 3D-Bioplotter system successfully facilitated numerous in-vitro and in-vivo experiments and publications.

Plasma Biototal Ltd – Stand 24

P L A S M A B I O T A L L I M I T E D

Plasma Biototal Ltd is a leading supplier of Hydroxylapatite (HA) coating services for orthopedic device manufacturers and manufacturers of ceramic materials for grafting products, composites and other advanced biomaterials to over 20 countries worldwide. Externally audited to requirements for international standards ISO 13779:2008, 13175:2012, and for quality systems ISO 13485, 9001, and ASTM standards.

Plasma Biototal Ltd

Unit 1-5 Meverill Road Industrial Estate
Whitecross Road
Tideswell
Derbyshire SK17 8PY

Royal Society of Chemistry – Stand 166

Royal Society of Chemistry

Thomas Graham House
Science Park
Milton Road
Cambridge CB4 0WF
UK
Tel: +44 (0)1223 420066
Fax: +44 (0)1223 423623
booksales@rcs.org
www.rsc.org

The Royal Society of Chemistry is the largest organisation in Europe for advancing the chemical sciences. Supported by a world-wide network of members and an international publishing business, our activities span education, conferences, science policy and the promotion of chemistry to the public. The Royal Society of Chemistry's high quality books programme covers the breadth of the chemical sciences, ranging from the highly specialised to educational textbooks and popular science titles.

Royal Society Publishing – Stand 70

Royal Society Publishing (The Royal Society)

6-9 Carlton House Terrace
London
SW1Y 5AG
UK
Tel: +44 (0)20 7451 2633
<http://royalsocietypublishing.org>
Representative: Ruth Milne

The Royal Society journals regularly publish high quality content in the area of biomaterials. For more information about the scope and editorial procedures of our journals, please come and have a chat with our representative Ruth Milne at booth number 70. Alternatively, visit our website at <http://royalsocietypublishing.org>

Spraybase-Profector Life Sciences – Stand 54

Spraybase - Profector Life Sciences

The logo for Spraybase® features the word "Spraybase" in a stylized, cursive-like font with a registered trademark symbol (®) to its upper right.

Electrospinning and Electrospaying Instruments

Value | Versatility | Expertise

1.08 Callan Building
NUI Maynooth
Kildare
Ireland
Tel: +353-85-7085045
ghendy@profector.com
www.spraybase.com

Spraybase® is the world's first integrated instrument that enables electrospinning and electrospaying technologies for life sci-ence applications. The Spraybase® instrument offers a complete solution to users investigating electrospaying and electrospin-ning applications. Spraybase® instrument can be used to form colloids and fibers of varying shape and size depending on your application.

WPI/Cell-Scale – Stand 172

World Precision Instruments / Cell-Scale

1 Hunting Gate
Hitchin
Herts
SG4 0TJ
Tel: +44 (0)1462 424700
Fax: +44 (0)1462 424701
idavies@wpi-europe.com
<http://www.wpi-europe.com/solutions/biomaterial-testing.aspx>
Representative: Dr. Ian Davies

Cell Scale mechanical test systems are specifically designed for characterizing the material properties of biomaterials. With integrated features such as image capture and analysis, media chambers, and a range of gripping mechanisms, their biaxial and micro-scale compression test systems are capable of generating high quality test data from day one.

Biomomentum Inc. – Stand 50

Biomomentum Inc.

970 Michelin, Suite 200
Laval, Quebec, H7L 5C1
Canada
Tel: (450) 677-2299
info@biomomentum.com
www.biomomentum.com
Representative: Martin Garon

Biomomentum specializes in providing solutions for testing biomaterials and cartilage. The Mach-1™ is a multiple-axis mechanical tester capable of performing compression, tension, shear, and torsion tests for the precise characterization and mechanical stimulation of cartilage and other soft tissue and materials. Among other functionalities, the Mach-1™ can be used to automatically map the mechanical properties of full articular cartilage surfaces in indentation. The Arthro-BST™ is a hand-held medical device used in conjunction with arthroscopy for the non-destructive measurement of compression-induced streaming potentials of articular cartilage. A benchtop version of this device is available for ex vivo use. Biomomentum also offers biomechanical testing services.

Elsevier

ELSEVIER

Elsevier is a world leading provider of scientific, technical and medical information, products and services. We publish high-impact articles across the whole of materials science, in bio-materials and polymers, in ceramics and composites, in alloys and compounds, in metals and in new materials for energy applications. We publish around 20,000 articles per year across our entire list and work globally with some of the best minds in the field to lead our journals. To support our program, we also run successful conferences such as *Frontiers in Polymer Science*, *Hybrid Materials*, *Nano Today*, *Materials Today Asia* and *NuMat: Nuclear Materials*.

Cook General Biotechnology

At Cook General BioTechnology, LLC, we're dedicated to advancing the science and practical application of processing, storage, and manufacturing of cells and tissues to empower new cell-based medical therapies. CGBT is proud to offer Stemulate™ to academic, medical centers, and industry partners. Stemulate™ is a substitute for fetal bovine serum (FBS) or serum free culture media. Its advantages include no risk of animal pathogen transmission, superior mesenchymal stromal cell growth kinetics (at 5% concentration) as well as reliable batch-to-batch consistency and performance.

Lifecore Biomedical – Stand 126

Lifecore is a leader in hyaluronan supply for commercial and research markets. These include applications in ophthalmology, orthopaedics, tissue engineering, aesthetics etc. Lifecore also offers Corgel® BioHydrogel and CellMate® hyaluronan-based 3D culture materials. Lifecore also has extensive experience in contract manufacturing.

The annual conference of the European Society for Biomaterials

27th European Conference on Biomaterials

www.esb2015.org

ESB 2015

30 August–3 September
Kraków, Poland

The organizers of the 10th World Biomaterials Congress (WBC) which will be held in Montreal May 18-22, 2016 welcome you to meet us at our booth at this European Society for Biomaterials meeting and to visit our website <http://www.wbc2016.org/> . The venue for the event is the Montreal Convention Center, located in the heart of downtown Montreal, just a minutes walk from the historic Old Montreal. We cordially invite you to participate in this exciting event as active organizers, reviewers, exhibitors and/or presenters. We encourage you to share your latest findings in science and technology of Biomaterials with others by submitting a paper, organizing a symposium session or sharing your ideas with us. Please feel free contact any of the four co-chairs for the conference or the conference office at info@wbc2016.org .

Key Dates

Call for Symposia: will open on September 15, 2014: New Frontier topics only; proposals for topics that are covered by the Scientific Sessions below will not be considered.

Call for Abstracts: will open on May 15, 2015

Biomaterials I Hall 1, 09:30 - 10:30

Chairs: Wim De Jong, National Institute for Public Health and the Environment
Matteo D'Este, AO Foundation
Felicity de Cogan, University of Birmingham

- 09:30 1-1 **A Viscoelastic, Anisotropic, Hyperelastic Model of the Human Cornea**
Charles Whitford, Natasha Movchan and Ahmed Elsheikh
School of Engineering, University of Liverpool, UK
- 09:45 1-2 **Bacterial Cellulose as a Support for the Growth of Retinal Pigment Epithelium**
S. Gonçalves, J. Padrão, J. Silva, I. Rodrigues, H. Girão, F. Dourado and L. Rodrigues
Center of Biological Engineering, University of Minho, Portugal
- 10:00 1-3 **Nanosomes: Novel Drug Delivery Vehicles to treat Glaucoma**
F. de Cogan, L. Hill, P. Morgan-Warren, J. O'Neill, A. Peacock, R. Scott and A. Logan
School of Clinical and Experimental Medicine, University of Birmingham, UK
- 10:15 1-4 **Emulation of Extracellular Matrix for the Development of Human Corneal Stromal Substitute**
Pramod Kumar, Abhigyan Satyam, Xingliang Fan, Brian Rodriguez, Yuri Rochev, Michael Raghunath, Abhay Pandit and Dimitrios Zeugolis
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland

Tissue Engineering I Room 3, 09:30 - 10:30

Chairs: Miguel Gama, Minho University
Ferry Melchels, University Medical Center Utrecht
Hugo Oliveira, Inserm U1026, Biotis

- 09:30 2-1 **Nanostructured Materials for Tissue Engineering: Nanofibres, Nanoparticles and Nanofilms**
Lucie Bacakova
Department of Biomaterials and Tissue Engineering, Academy of Sciences of the Czech Republic, Prague
- 09:45 2-2 **Fabrication of Silk Fibroin and High Methoxyl Citrus Pectin(HMP) Based 3D Scaffolds for Bone Tissue Engineering**
Sibel Ataoğlu, Dilek Keskin, Akın Akdağ, Ayşen Tezcaner
Department of Biomedical Engineering, Middle East Technical University, Ankara, Turkey
- 10:00 2-3 **Regulation of Chondrocyte Spheroid Size using Proline-containing Periodic Peptides**
N. Takata, Y. Morita, Y. Hirano, Y. Futaki and E. Nakamachi
Graduate School of Life and Medical Sciences, Doshisha University, Japan
- 10:15 2-4 **Hyaluronic Acid Based-Hydrogels Attenuate Inflammatory Receptor and Neurotrophins in IL-1 β Induced Inflammation Model of Nucleus Pulposus Cell Cultures**
Isma-Liza Mohd-Isa, David Tiernan, Akshay Srivastava, Peter Rooney and Abhay Pandit
Network of Excellent Functional Biomaterials, National University of Ireland, Galway, Ireland

Stem Cells I Room 11, 09:30 - 10:30

Chairs: Barbara Boyan, Virginia Commonwealth University
Tugba Dursun, Middle East Technical University
Jerome Sohler, Centre National de la Recherche Scientifique

- 09:30 3-1 **Osteogenic Activity of Adipose Derived Stem Cells on Micropatterned Collagen-Fibroin Blend Films**
E. Sayin, E. T. Baran, V. Hasirci
Department of Biotechnology, Middle East Technical University, Turkey
- 09:45 3-2 **Regulation of Mesenchymal Stem Cell Differentiation by Changing the Molecular Structure of Supramolecular Surfaces**
Ji-Hun Seo, Sachiro Kakinoki, Tetsuji Yamaoka and Nobuhiko Yui
Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University, Japan
- 10:00 3-3 **Cell Viability and Cell Attachment of Mesenchymal Stem Cells on Hydroxyapatite/Alginate S. crassifolium Composite Scaffolds**
Decky J. Indrani, Ismail Dilogo, Yuyus Kusnadi
Department of Dental Materials Science, University of Indonesia
- 10:15 3-4 **The Development and Translation of a Cell Capture Technique for Cell Therapies, Diagnostics and Research**
Nicholas Bryan, Damian Bond, Christopher Stanley and John Alan Hunt
Clinical Engineering, Institute of Ageing and Chronic Disease, University of Liverpool, UK

Chairs: Giorgio Soldani, IFC-CNR

Kambiz Farbod, Radboud University Medical Center

Coline Jumeaux, Imperial College London

- 09:30 4-1 **Dynamic Polysaccharide-based Carrier Systems for the Delivery of Biotherapeutics**
Denise N. Bamberger and Peter R. Wich
 Institut für Pharmazie und Biochemie, Johannes Gutenberg-Universität Mainz, Germany
- 09:45 4-2 **Amphiphilic Graft Polyester-g-polysaccharide Copolymers for Sustained Drug Release**
L. Martellotto, J. Buisson, H. Van Den Berghe, J. Coudane
 Artificial Biopolymers Department, University Montpellier 1, France
- 10:00 4-3 **Micro and Nano Systems in Medical Applications**
Vasif Hasirci, Eda Ayse Aksoy and Nesrin Hasirci
 Middle East Technical University, Chemistry Dept, Ankara, Turkey
- 10:15 4-4 **Fibrin-based Microsphere Reservoirs for Delivery of Neurotrophic Factors**
Juhi Samal, *Ellis Dowd and Abhay Pandit*
 Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland

Dental Biomaterials I Room 1C, 09:30 - 10:30

Chairs: Judith Curran, University of Liverpool

Anas Aljabo, University College London

Sabeel Valappi, University of Liverpool

- 09:30 5-1 **Synthesis and Evaluation of a Novel POSS-PEG-PLA Hydrogel for Periodontal Applications**
David K. Wang, Srinivas Varanasi, David J.T. Hill, Anne L. Symons, Andrew K. Whittaker and Firas A. Rasoul
 Australian Institute for Bioengineering and Nanotechnology, University of Queensland, Brisbane, Australia
- 09:45 5-2 **Effects of Calcium Phosphate and an Adhesion Promoting Monomer on Strength, Degree of Conversion and Adhesion of Dental Composites**
Anas Aljabo and *Anne Young*
 Biomaterials and Tissue Engineering, University College London, UK
- 10:00 5-3 **The Bone-Implant Interface – Nano-Osseointegration of Functionally Loaded, Nano-Textured, Human Dental Implants**
Furqan A. Shah, *Bengt Nilson, Rickard Brånemark, Peter Thomsen, Anders Palmquist*
 Department of Biomaterials, University of Gothenburg, Sweden
- 10:15 5-4 **Morphology, Surface Chemistry and Mechanical Properties of Commercial Guided Tissue Regeneration Membranes**
Pascal Borget, *Paul G. Rouxhet and Eric Rompen*
 Unité de Chimie des Interfaces, Université Catholique de Louvain, Belgium

Chairs: Wim De Jong, National Institute for Public Health and the Environment
Matteo D'Este, AO Foundation
Felicity de Cogan, University of Birmingham

- 11:00 6-1 **Dense Fibrillated Collagen Transparent Matrices as Artificial Corneas?**
Aurelien Tidu, Djida Ghoubay, Barbara Lynch, Céline De Sousa, Frank Wendel, Jean-Marc Allain, Vincent Borderie, Gervaise Mosser
Sorbonne Université, Paris, France
- 11:15 6-2 **Cytotoxicity of Terbium-Crown Ether Complex Against Acanthamoeba sp. - A Causative Agent for Eye Keratitis**
Eny Kusriji, Fatimah Hashim, Dewi Tristantini, Nurfatin Solehah Bustaman and Nakisah Mat Amin
Department of Chemical Engineering, Faculty of Engineering, Universitas Indonesia
- 11:30 6-3 **Biodegradable Nanoneedles for Intracellular Sensing of Enzymatic Activity**
Ciro Chiappini, Paola Campagnolo, Carina Almeida, Lesley Chow, Molly M. Stevens
Department of Materials, Imperial College London, UK
- 11:45 6-4 **Biosurface Induced Protein Manipulation for Measurement of Dynamic Platelet Function**
D. Bishop, J. Cowman, E. Dunne, D. Kenny, A. Boyd and B. Meenan
Nanotechnology and Integrated Bioengineering Centre, University of Ulster, UK
- 12:00 6-5 **Targeted Gene Delivery into Peripheral Nervous System Mediated by Trimethyl Chitosan Nanoparticles**
Carla Pereira Gomes, Aida Varela-Moreira, Maria Gomez-Lazaro, Michael Leitner, Andreas Ebner, Peter Hinterdorfer, Ana Paula Pêgo
Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- 12:15 6-6 **Nanoscale Neuroelectrode Modification Through Self-Assembly of Block Copolymers**
Parvaneh Mokarian-Tabari, Catalina Vallejo-Giraldo, Marc Fernandez-Yague, Cian Cummins, Michael A. Morris and Manus J.P. Biggs
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway

Tissue Engineering II Room 3, 11:00 - 12:30

Chairs: Miguel Gama, Minho University
Ferry Melchels, University Medical Center Utrecht
Hugo Oliveira, Inserm U1026, Biotis

- 11:00 7-1 **Stimulation of Angiogenesis by Growth Factor-free Porous Adhesive Films Made by Hexanoyl Group Modified Gelatin**
Keiko Yoshizawa, Temmei Ito, Ryo Mizuta and Tetsushi Taguchi
Graduate School of Pure and Applied Science, University of Tsukuba, Japan
- 11:15 7-2 **Development of PLLA/BTO Nanofiber Sheet for Bone Tissue Engineering**
A. Yamano, Y. Morita and E. Nakamachi
Graduate School of Life and Medical Sciences, Doshisha University, Japan
- 11:30 7-3 **Preparation and Characterization of PHBV Porous Nanofibers**
Lan-Xin Lyu, Ning-Ping Huang and Ying Yang
State Key Laboratory of Bioelectronics, Southeast University, China
- 11:45 7-4 **Fabrication and Characterization of Carbon Nanotube Membranes for Neural Tissue Engineering**
Sevde Altuntas, Buket Altınok, Belma Aslım, Fatih Buyukserin
Micro and Nanotechnology Graduate Program, TOBB Univ. of Econ. & Technology, Ankara, Turkey
- 12:00 7-5 **A Degradable Chitosan-graft-poly(ϵ -Caprolactone) Copolymeric Biomaterial Supports the Growth of Wharton's Jelly Mesenchymal Stem Cells for Soft Tissue Engineering**
Amalia Skarmoutsou, Costas Charitidis, Maria Kaliva, Charalampos Pontikoglou, Maria Vamvakaki, Maria Chatzinikolaïdou
Department of Materials Science and Technology, University of Crete, Greece
- 12:15 7-6 **Application of Natural BMP Modulators on Bone Tissue Engineering**
Guo-Chung Dong and Chun-Hsu Yao
Institute of Biomedical Engineering and Nanomedicine, National Health Research Institutes, Taiwan

Stem Cells II Room 11, 11:00 - 12:30

Chairs: Barbara Boyan, Virginia Commonwealth University
Tugba Dursun, Middle East Technical University
Jerome Sohler, Centre National de la Recherche Scientifique

- 11:00 8-1 **Substrate-Mediated Nanoparticle/Gene Delivery to MSC Spheroids and the Applications in Peripheral Nerve Regeneration**
Ting-Chen Tseng and Shan-hui Hsu
Institute of Polymer Science and Engineering, National Taiwan University, Taipei, Taiwan
- 11:15 8-2 **Influence of Inner Organization of Nerve Guide on Rat Bone Marrow Stem Cells (rBMSCs)**
T. Dursun, D. Yücel, V. Hasırcı
BIOMATEN, Middle East Technical University Center of Excellence in Biomaterials and Tissue Engineering, Ankara, Turkey
- 11:30 8-3 **Designing 3D Cell Niches Exploiting Peptide Self-Assembly**
Victoria L. Workman, Aline F. Miller and Alberto Saiani
School of Materials, University of Manchester, UK
- 11:45 8-4 **Effect of Zinc-Containing Tricalciumphosphate (ZnTCP) on Growth and Osteogenic Differentiation of Mesenchymal Stem Cells**
Joshua Chou, Jia Hao, Hirokazu Hatoyama, Besim Ben-Nissan, Bruce Milthorpe, Makoto Otsuka
Advanced Tissue Regeneration and Drug Delivery Group, University of Technology Sydney, Australia
- 12:00 8-5 **High-Throughput Quantitative Chondrogenic Assay for Stem Cell Differentiation**
Amy Prosser, Colin Scotthford, Virginie Sottile, and David Grant
Division of Materials Mechanics and Structures, University of Nottingham, UK

- 12:15 8-6 **Advances in Raman Micro-Spectroscopy for Label-free Monitoring Differentiation of Stem Cells In-Vitro**
Ioan Notingher
 School of Physics and Astronomy, University of Nottingham, United Kingdom

Drug Delivery II Room 1B, 11:00 - 12:30

- Chairs:** Giorgio Soldani, IFC-CNR
 Joana Magalhaes, Instituto de Salud Carlos III
 Coline Jumeaux, Imperial College London
- 11:00 9-1 **Substrate Mediated Enzyme Prodrug Therapy**
A.N. Zelikin
 Department of Chemistry, Aarhus University, Denmark
- 11:15 9-2 **Mesoporous SiO₂-ZnO-plex: Mechanistic Approach, Complex of Nanoparticles of SiO₂-ZnO with DNA for Therapeutic Applications**
 Vijay Bhooshan Kumar, Koushi Kumar, Yitzhak Mastai, Aharon Gedanken, Pradip Paik
 School of Engineering Sciences and Technology, University of Hyderabad, India
- 11:30 9-3 **Estimation of Drug Loading Efficiency in Microspheres by “Shake Flask” Method**
 C. Y. Tham, Z. A Abdul Hamid, Z. Ahmad, H. Ismail
 School of Materials and Mineral Resources Engineering, Universiti Sains Malaysia, Seri Ampangan, Malaysia
- 11:45 9-4 **Suzuki Coupling-Functionalized Boronic Acid Nanoparticles for Drug Delivery**
André J. van der Vlies and Urara Hasegawa
 Graduate School of Engineering, Osaka University, Japan
- 12:00 9-5 **Polymeric Micelles for Hydrogen Sulfide-Based Therapy**
Urara Hasegawa, André J. van der Vlies
 Graduate School of Engineering, Osaka University, Japan
- 12:15 9-6 **Amorphous Coordination Polymer Particles. From Basic Macromolecular Science to Theranostic Applications**
F. Novio, F. Nador, K. Wnuk, M. Borges and D. Ruiz-Molina
 Centro de Investigación en Nanociencia y Nanotecnología, Consejo Superior de Investigaciones Científicas, Bellaterra, Spain

Dental Biomaterials II Room 1C, 11:00 - 12:30

- Chairs:** Judith Curran, University of Liverpool
 Anas Aljabo, University College London
 Sabeel Valappi, University of Liverpool
- 11:00 10-1 **Potential Use of 7-dehydrocholesterol Coated Titanium Surfaces for Soft Tissue Integration of Dental Implants**
Manuel Gómez-Florit, María Satué, Joana M. Ramis and Marta Monjo
 Group of Cell Therapy and Tissue Engineering, University of the Balearic Islands, Spain
- 11:15 10-2 **Studying Interaction between Oral Mucosa and Titanium by SEM in Humans**
Francesco Tassarolo, Cristiano Tomasi, Federico Piccoli, Iole Caola, Patrizio Caciagli and Giandomenico Nollo
 Bruno Kessler Foundation, Trento, Italy
- 11:30 10-3 **Synthesis and Characterisation of Novel Diopside Glass-Ceramics for Dentistry**
J. Almuhamadi, N. Karpukhina and M. Cattell
 Institute of Dentistry, Queen Mary University of London, UK
- 11:45 10-4 **Functionally Graded Guided Tissue Regenerative (GTR) Membrane for Periodontal Lesions**
S Qasim, R Delaine-Smith, A. Rawlinson, I. Rehman
 Materials Science and Engineering Department, University of Sheffield, UK
- 12:00 10-5 **Bioactivity Investigations with Calcia Magnesia Based composites**
 Emad Ewais, Amira Moustafa, Karoline Pardun, Kurosch Rezwan
 Advanced Materials Department, Central Metallurgical R&D Institute, Cairo, Egypt
- 12:15 10-6 **Characterisation of Partially-Demineralised Dentine is a Prerequisite for Remineralisation Studies**
Eleanor Ashworth, Cheryl Miller, Christopher Deery and Nicolas Martin
 School of Clinical Dentistry, University of Sheffield, UK

Chair: Joachim Kohn, Rutgers University

The Race between engineering and biology in replacing human tissues.

The chair will define this challenge, a take vote of the audience. There will then be 6, 15 minute talks from a panel of current FBSE fellows:

- 14:00 **Barbara Boyan**, Virginia Commonwealth University
- 14:15 **Rui Reis**, University of Minho
- 14:30 **Abhay Pandit**, National University of Ireland Galway
- 14:45 **Cristina Tanzi**, Politecnico di Milano
- 15:00 **John Kao**, University of Wisconsin - Madison
- 15:15 **David Williams**, Wake Forest Institute of Regenerative Medicine

who will expound, sometimes controversially, their own points of view about the argument.

Following the talks there will be a Q & A session and finally a vote of the audience.

YSF Entrepreneurship Workshop Room 3, 13:30 - 16:00

Chairs: Lorenzo Moroni, University of Twente
Sandra Van Vlierberghe, University of Gent
Anna Wistrand, KTH Royal Institute of Technology

The workshop will give a flavour of what it takes to create spin-off companies from innovative research activities that take place at Universities, as well as in Industry. Talks will span from personal experiences in facing the challenges of setting up a spin-off, to the availability of educational programmes and important points to consider when applying for patents.

The afternoon has an extensive spectrum of experienced experts in entrepreneurship:

- 13:35 **Dirk Grijpma**, University of Twente
- 14:00 **Dietmar Huttmacher**, Queensland University of Technology and Technical University of Munchen
- 14:25 **Jens Thies**, DSM, The Netherlands
- 14:50 **Chris Sutcliffe**, University of Liverpool
- 15:10 **Alex Sim**, AMSBIO Ltd
- 15:35 **Chris Unsworth**, Business Gateway, University of Liverpool

European Doctoral Awards Hall 1, 16:30 - 17:30

Chair: Dirk Grijpma, University of Twente

- 16:30 **Award presentations**
Dirk Grijpma
University of Twente, the Netherlands
- 16:40 14-1 **Periodontal Regeneration by Combining Melt Electrospinning With Fused Deposition Modelling and Cell Sheet Technologies**
Pedro Costa
Technische Universität München, Germany
- 16:50 14-2 **Development of a Pro-Angiogenic Cell-Delivery Vehicle Based on RGD-Alginate Hydrogels**
Silvia Bidarra
University of Porto, Portugal
- 17:00 14-3 **The Osteogenic Potential of Human Mesenchymal Stem Cells - Connections to Inflammation and Infection**
Cecilia Granéli
University of Gothenburg, Sweden
- 17:10 14-4 **Influence of Sintering Conditions on the Properties of Porous TiO₂ Bone Scaffolds**
Hanna Tiainen
University of Oslo, Norway
- 17:20 14-5 **Biomaterials for 2D and 3D Bio-Hybrid Robotic Devices**
Leonardo Ricotti
Scuola Superiore Sant'Anna, Italy

Chairs: Liang Yo Yang, Taipei Medical University
Oscar Castaño, Institute for Bioengineering of Catalonia
Thomas Miramond, Biomatlante

- 09:00 15-1 **Self-Healing Hybrid Nanocomposites Based on Bisphosphonated Hyaluronan and Calcium Phosphate Nanoparticles for Bone Regeneration**
Reza Nejadnik, Xia Yang, Matilde Bongio, Hamdan S. Alghamdi, Jeroen J.J.P. van den Beucken, Marie C. Huysmans, John A. Jansen, Jöns Hilborn, Dmitri Ossipov and Sander C.G. Leeuwenburgh
Department of Chemistry-Ångström, Uppsala University, Sweden
- 09:15 15-2 **Development of Novel LZ-8 protein-Containing Porous Composite Sponge Scaffold for Biomedical Applications: Biocompatibility Evaluation and an Animal Study in Rabbit**
Chia-Yin Chen, His-Jen Chiang, Li-Hsiang Lin, Keng-Liang Ou
Graduate Institute of Biomedical Materials and Tissue Engineering, Taipei Medical University, Taiwan
- 09:30 15-3 **Phase Constitution and Heat Treatment Behaviour of Ti-Mn-Sn Beta Type Alloys**
Masahiko Ikeda, Masato Ueda and Mitsuo Niinomi
Department of Chemistry and Materials Engineering, Kansai University, Japan
- 09:45 15-4 **Hyaluronic Acid Bound Bisphosphonates As A Novel Therapeutic Strategy For Osteoporosis**
Sujit Kootala, Dmitri Ossipov, Xia Yang, Yu Zhang and Jöns Hilborn
Department of Chemistry/Polymer Chemistry, Uppsala University, Sweden
- 10:00 15-5 **Influence of Anchor Strand Related Parameters on Immobilized Amount and Hybridization Efficiency in a Nucleic Acid-based Immobilization System for Titanium Implants**
Cornelia Wolf-Brandstetter, Jan Michael, René Beutner, Bernd Schwenzer, Henning Schliephake, Dieter Scharnweber
Institute of Materials Science, TU Dresden, Germany
- 10:15 15-6 **Functional Octapeptide Hydrogel to Bone Repair Applications**
Luis Castillo, Alberto Saiani, Julie Gough and Aline Miller
Manchester Interdisciplinary Biocentre, University of Manchester, UK

Biomaterials III Room 3, 09:00 - 10:30

Chairs: Dietmar Hutmacher, Queensland University of Technology
Rui Reis, University of Minho
Patrik Stenlund, SP Technical Research Institute of Sweden

- 09:00 16-1 **Pro-inflammatory Response to Novel Gelatin-based Biomaterials with Tailorable Mechanical Properties in vitro**
Sandra Ullm, Anne Krueger, Tim P. Gebauer, Axel T. Neffe, Christoph Tondera, Andreas Lendlein, Friedrich Jung, Jens Pietzsch
Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Germany
- 09:15 16-2 **Dissecting the Regulating Cues of the Extracellular Matrix in Macrophage Plasticity**
Katja Franke, Liv Kalbitzer, Jiranuwat Sapudom, Ulf Andereg, Sandra Franz and Tilo Pompe
Institute of Biochemistry, Universität Leipzig, Germany
- 09:30 16-3 **Carbon Monoxide Releasing Nanoparticles**
Ryosuke Inubushi, André J. van der Vlies, Hiroshi Uyama and Urara Hasegawa
Graduate School of Engineering, Osaka University, Japan
- 09:45 16-4 **Effect of Hydrophobic Groups on the Bonding Strength of Cod-Derived Gelatins-Based Tissue Adhesives**
Tetsushi Taguchi, Temmei Ito, Ryo Mizuta, Keiko Yoshizawa
Biomaterials Unit, National Institute for Materials Science, Japan
- 10:00 16-5 **Examination of Local and Systemic Inflammatory and Immunological Reactions Following Implantation of Jellyfish Collagen Matrices in Rats**
Uwe Walschus, Susanne Meyer, Silke Lucke, Andreas Hoene, Udo Meyer, Michael Schlosser
Department of Medical Biochemistry and Molecular Biology, University Medical Center Greifswald, Germany
- 10:15 16-6 **Sulfated Hyaluronan Derivatives Interfere with TGF- β 1 Signalling**
V. Hintze, A. van der Smissen, S. Samsonov, L. Huebner, S. Rother, D. Scharnweber, S. Moeller, M. Schnabelrauch, M. T. Pisabarro, U. Andereg
Max Bergmann Center of Biomaterials, Technische Universität Dresden, Germany

Cardiovascular I: TECAS-ITN Room 11, 09:00 - 10:30

Chairs: Dimosthenis Mavrilas, University of Patras
Petra Mela, RWTH Aachen

- 09:00 17-1 **Vascular Network Generation in Hyaluronic Acid by Micromolding and Photoimmobilization of Fibronectin**
A. Kömez, E. T. Baran, N. Hasirci, V. Hasirci
Department of Biotechnology, Middle East Technical University, Turkey
- 09:15 17-2 **Collagen(I)-Poly(Glycerol Sebacate)/Poly(Butylene Succinate-Dilinoate) Fibrous Scaffolds for Cardiac Tissue Engineering**
Marwa Tallawi, David C. Zebrowski, Aga Kozłowska, Mirka El Fray, Felix B. Engel, Aldo R. Boccaccini
Institute of Biomaterials, University of Erlangen-Nuremberg, Germany
- 09:30 17-3 **Tri-Culture of Vascular Cells Promotes Vascular Tissue Remodeling**
Caroline Loy, Lucie Levesque, Jayachandran Kizhakkedathu, Diego Mantovani
Lab for Biomaterials and Bioengineering, Laval University, Quebec, Canada
- 09:45 17-4 **Nanofibrous Vascular Grafts Releasing Nitric Oxide**
Jana Horakova, Connor McCarthy, Megan Frost, Jeremy Goldman, David Lukas, Petr Mikes
Department of Nonwovens and Nanofibrous Materials, Technical University of Liberec, Czech Republic

- 10:00 17-5 **Electrospun Silk Fibroin/Gelatin Composite Tubular Matrices as Scaffolds for Small Diameter Blood Vessel Regeneration**
Chiara Marcolin, Valentina Catto, Federica D'Agostino, Serena Bertoldi, Silvia Farè, Maria Cristina Tanzi
 Department of Chimica, Materiali e Ingegneria Chimica "G. Natta", Politecnico di Milano, Italy
- 10:15 17-6 **Design and synthesis of supramolecular biomaterials for in-situ cardiovascular tissue engineering**
Olga JGM Goor, Geert C van Almen and Patricia YW Dankers
 Institute for Complex Molecular Systems, Eindhoven University of Technology, The Netherlands

Imaging I Room 1B, 09:00 - 10:30

Chairs: Julie Gough, University of Manchester
 Gavin Jell, University College London
 Alfredo Ronca, National Research Council of Italy

- 09:00 18-1 **Tissue Response and Degradation of Novel Gelatin-Based Biomaterials in vivo: Insights from Small Animal Multimodal Imaging**
Christoph Tondera, Sandra Ullm, Sebastian Meister, Tim P. Gebauer, Axel T. Neffe, Andreas Lendlein, Jens Pietzsch
 Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Germany
- 09:15 18-2 **Systemically Injected Gold-Silica Hybrid Nanovectors for Combined Cancer Therapy and Imaging**
Coline Jumeaux, Ciro Chiappini, Rona Chandrawati, Matthew Hembury, Glenna L. Drisko, Cédric Boissière, Clément Sanchez, Alexandra Porter, Molly M. Stevens
 Department of Materials, Imperial College London, London
- 09:30 18-3 **Superparamagnetic Iron Oxide Nanoparticles Stabilized by Dextran Nanogel: New Nanomagnetogel as Contrast Agent for Magnetic Resonance Imaging. Biodistribution**
Catarina Gonçalves, Yoann Lalatonne, Liliana Melro, Giorgio Badino, Miguel Ferreira, Laurence Motte, Carlos Geraldès, José Alberto Martins, F. M. Gama
 Centre for Biological Engineering, Minho University, Braga, Portugal
- 09:45 18-4 **A Non-Toxic Additive to Introduce X-Ray Contrast into Poly(lactic acid)s**
Leo H. Koole, Daniel G. Molin and Yujing Wang
 Department of Biomedical Engineering, Maastricht University, The Netherlands
- 10:00 18-5 **Novel Technique to Map the Biomechanical Properties of Entire Articular Surfaces Using Indentation to Identify Early Osteoarthritis-like Regions**
Sotcheadt Sim, Anik Chevrier, Martin Garon, Eric Quenneville and Michael D. Buschmann
 Biomomentum Inc., Canada
- 10:15 18-6 **Polymer Coating for in vivo MR Visualization of Tissue Reinforcement Prostheses**
X. Garric, S. Blanquer, O. Guillaume, V. Letouzey, L. Lemaire, F. Franconi, R. DeTayrac, J. Coudane
 IBMM, Artificial Biopolymers Group, Montpellier, France

Antimicrobials, Biofilms and Surfaces Symposium, part 1 Room 4, 09:00 - 10:30

Chairs: Steven Percival, Scapa Healthcare
 Sara Svensson, University of Gothenburg
 Kenny Omoniala, De Montford University

- 09:00 19-1 **s. Aureus Evades Leukocyte Antimicrobial and Mesenchymal Stromal/stem Cell Immunomodulatory Functions**
David Antonio Cantu, Warren E. Rose, Peiman Hematti, Weiyan John Kao
 School of Pharmacy, University of Wisconsin-Madison, USA
- 09:15 19-2 **Preparation and Characterisation of an Antibacterial Silver-doped Nanoscale Hydroxyapatite Paste**
Caroline Wilcock, Monazza Fatima, Piergiorgio Gentile, Graham Stafford, Cheryl Miller, Yulia Ryabenkova, Guenter Möbus, Paul Hatton
 Centre for Biomaterials and Tissue Engineering, University of Sheffield, UK
- 09:30 19-3 **Comparisons of the Properties of Linear and Highly-Branched Poly(N-isopropyl acrylamide) with Ligands that Bind Bacteria**
P. Teratanatorn, R. Hoskins, J. Shepherd, K. Swindells, T. Swift, L. Swanson, S. MacNeil, I. Douglas, S. Rimmer
 University of Sheffield, UK
- 09:45 19-4 **Nanoscale Characterization of Cationic Polymeric Brushes and Bacterial Interactions Probed by Force Microscopy**
Merve Gultekinoglu, Yoo Jin Oh, Memed Duman, Peter Hinterdorfer and Kezban Ulubayram
 Faculty of Pharmacy, Hacettepe University, Turkey
- 10:00 19-5 **Effect of pH and Biofilm Formation on Extracellular Matrix Synthesis in Normal and Chronic Wound Fibroblasts**
Eleri M Jones, Steven Percival, Peter Clegg, John A Hunt and Christine A Cochrane
 Institute of Ageing of Chronic Disease, University of Liverpool, UK
- 10:15 19-6 **Hybrid Material (Chitosan Hydrogel/Bioceramic) Loaded with Ciprofloxacin or Simvastatin for Bone Reconstruction**
Claudia Flores, Jean Christophe Hornez, Feng Chai, Gwenaél Raoul, Juergen Siepmann, Joel Ferri, Bernard Martel, H. Frederic Hildebrand, Nicolas Blanchemain
 INSERM U1008, Biomaterials Research Group, University Lille 2, France

Chairs: Liang Yo Yang, Taipei Medical University
Oscar Castaño, Institute for Bioengineering of Catalonia
Thomas Miramond, Biomatlante

- 11:00 20-1 **Development of Bisphosphonate-functionalized Gelatin Nanoparticles for Application in Colloidal Hydrogels for Bone Regeneration**
K. Farbod, J.A. Jansen and S.C.G. Leeuwenburgh
Department of Biomaterials, Radboud University Medical Center, The Netherlands
- 11:15 20-2 **Tough Silica/PCL Hybrid Materials for Tissue Regeneration**
F. Tallia, L. Russo, L. Gabrielli, L. Cipolla, J.R. Jones
Department of Materials, Imperial College London, UK
- 11:30 20-3 **New Gelatine Functionalized Hybrid Sol-gel Coatings for Titanium Implants**
I. Lara-Sáez, M. Martínez-Ibáñez, S. Barros, A. Coso, J. Franco, M. Gurruchaga, J. Suay, I. Goñi
Biomaterials and Tissue Engineering Center, Universitat Politècnica de València, Spain
- 11:45 20-4 **On the Applicability of Magnesium-containing Layered Double Hydroxides as Novel Implant Coating Materials**
Marc D. K. Kieke, Andreas Weizbauer, Franziska Duda, M. Imran Rahim, Philip Dellinger, Stefan Budde, Thilo Flörkemeier, Julia Diekmann, Nils K. Prenzler, Muhammad Badar, Peter P. Müller, Hansjörg Hauser, Sabine Behrens, Kai Möhwald, Friedrich Wilhelm Bach, Hans J. Maier, Thomas Lenarz, Henning Windhagen, Peter Behrens
Institute for Inorganic Chemistry, Leibniz University of Hannover, Germany
- 12:00 20-5 **Fatigue Characterization of Two Bone Cements Tested Using Various Methods over a Range of In Vitro Stress Amplitudes**
E.M. Sheafi and K.E. Tanner
School of Engineering, University of Glasgow, UK
- 12:15 20-6 **Functionalization of Titanium Surfaces with $\alpha\beta 3$ and $\alpha 5\beta 1$ Integrin Selective Peptidomimetics: Influence on Osteoblast-like Cell Behavior**
Roberta Fraioli, Florian Rechenmacher, Stefanie Neubauer, José María Manero, Javier Gil, Horst Kessler, Carlos Mas-Moruno
Biomaterials, Biomechanics and Tissue Engineering Group, Universitat Politècnica de Catalunya, Spain

Biomaterials IV Room 3, 11:00 - 12:30

Chairs: Dietmar Hutmacher, Queensland University of Technology
Rui Reis, University of Minho
Patrik Stenlund, SP Technical Research Institute of Sweden

- 11:00 21-1 **Impact of Different Sterilization Methods on the Structure, Biodegradation and Cell Response of Collagen Scaffolds Designed for Peripheral Nerve Regeneration**
Graziana Monaco, Rahmat Cholas, Luca Salvatore, Marta Madaghiele, Alessandro Sannino
Department of Engineering for Innovation, University of Salento, Italy
- 11:15 21-2 **Artificial Immune Synapses; Nanoscale Control of Immune Cell Activation**
D. Delcassian, D. Depoil, D. Rudnicka, M. Liu, D. M. Davis, M. L. Dustin and I. E. Dunlop
Department of Materials, Imperial College London, UK
- 11:30 21-3 **New Approaches to Control the Host Response to Gold-based Biomaterials**
Guillaume Le Saux, Annabelle Tanga, Laurent Plawinski, Sylvain Nlate, Jean Ripoché and Marie-Christine Durrieu
Institute of Chemistry & Biology of Membranes & Nanoobjects (UMR 5248), Université Bordeaux, France
- 11:45 21-4 **Influence of Hyaluronic Acid Molecular Weight on the Biocompatibility of Chitosan/Hyaluronic Acid Multilayer Film**
Jing Jing, Aurélie Moniot, Céline Mongaret, Saad Mechiche-Alami, Romain Reynaud, Frédéric Velard, Sophie C. Gangloff, Loic Jerry, Fouzia Boulmedais and Halima Kerdjoudj
EA 4691 "Biomatériaux et inflammation en site osseux", Université de Reims Champagne-Ardenne, France
- 12:00 21-5 **Cytotoxicity of Functionalized Ggraphene to Osteoblast-like Cells**
Anke Bernstein, Dirk Heinrich, Norbert P. Südkamp, Hermann O. Mayr, Michael Seidenstücker, Ralf Thoman, Markus Stürzel, Rolf Mülhaupt
Department of Orthopedic and Trauma Surgery, Albert Ludwig University of Freiburg, Germany
- 12:15 21-6 **Subcutaneous Evaluation Of a Novel Pro-angiogenic Biomaterial For In Situ Bone Tissue Engineering Applications**
Hugo Oliveira, Nadege Sachot, Sylvain Catros, Sylvie Rey, Oscar Castano, Joëlle Amedee, Elisabeth Engel
Inserm U1026, Tissue Bioengineering, University Bordeaux Segalen, France

Cardiovascular II: TECAS-ITN Room 11, 11:00 - 12:30

Chairs: Dimosthenis Mavrilas, University of Patras
Petra Mela, RWTH Aachen

- 11:00 22-1 **Gene Targeting Nanoparticles to Mediate Proliferation and Migration of Human Vascular Endothelial Cells**
Yakai Feng, Juan Lv, Jing Yang and Changcan Shi
School of Chemical Engineering and Technology, Tianjin University, China
- 11:15 22-2 **Developing Multi-layered Vascular Grafts from a Novel Collagen and Elastin Biomaterial**
Alan J. Ryan, Fergal J. O'Brien
Tissue Engineering Research Group, Royal College of Surgeons in Ireland
- 11:30 22-3 **Elastomeric Biomaterials of Enhanced Microbiological and Mechanical Performance for Heart Assisting Devices**
A. Piegat, M. Piatek-Hnat, Z. Staniszewski, R. Kustosz, M. Gonsior, M. El Fray
West Pomeranian University of Technology, Szczecin, Poland
- 11:45 22-4 **Supercritical Carbon Dioxide (sc-CO₂) Assisted Decellularisation of Aorta**
Selcan Guler, Pezhman Hosseinian, Esin Akbay, Mehmet Ali Onur, Halil Murat Aydin
Bioengineering Division, Hacettepe University, Ankara, Turkey

- 12:00 22-5 **Hemocompatibility Assessment of Uncoated and Heparin Coated Styrenic Block Copolymers for Cardiovascular Applications**
Jacob Brubert, Joanna Stasiak, Geoff Moggridge and Hans Peter Wendel
 Department of Chemical Engineering and Biotechnology, University of Cambridge, UK
- 12:15 22-6 **Capillary Morphogenesis of Primary Endothelial Mono- and Co-cultures in starPEG-Heparin Hydrogels for Controlled Vascularization**
Uwe Freudenberg, Karolina Chwalek, Mikhail V. Tsurkan, and Carsten Werner
 Leibniz Institute of Polymer Research Dresden (IPF), Max Bergmann Center of Biomaterials, Dresden, Germany

Meaning of Surface Charge for Characterisation Symposium Room 1B, 11:00 - 12:30

Chairs: Christine Körner, Anton Paar GmbH

- 11:00 23-1 **The Zeta Potential as Indicator for Solid Surface Charge**
Christine Körner and Thomas Luxbacher
 Anton Paar GmbH, Austria
- 11:30 23-2 **Zeta Potential: a Useful Tool to Interpret the Hydrothermally Treated Titanium Behaviour as Biomaterial**
Martina Lorenzetti, Thomas Luxbacher, Spomenka Kobe and Saša Novak
 Department of Nanostructured Materials, Jožef Stefan Institute, Ljubljana, Slovenia
- 12:00 23-3 **The Role of Porosity on the Z-Potential of Calcium Phosphate Cements**
Montserrat Espanol, Gemma Mestres, Thomas Luxbacher and Maria-Pau Ginebra
 Department of Materials Science and Metallurgical Engineering, Technical University of Catalonia, Spain

Antimicrobials, Biofilms and Surfaces Symposium, part 2 Room 4, 11:00 - 12:30

Chairs: Steven Percival, Scapa Healthcare
 Sara Svensson, University of Gothenburg
 Kenny Omoniala, De Montford University

- 11:00 24-1 **The Effect of Surface Oxygen Functional Groups on Parylene C Biocompatibility - Comparison of MG-63 Cells Adhesion and Bacteria Strains Attachment**
M. Góda-Cepa, M. Brzychczy-Włoch, K. Envall, A. Kotarba
 Faculty of Chemistry, Jagiellonian University, Krakow, Poland
- 11:15 24-2 **Coating Nonwoven Polyester Textile Antibacterial Wound Dressing**
François Aubert-Viard, Oumaira Rahmouni, Adeline Martin, Feng Chai, Nicolas Tabary, Christel Neut, Bernard Martel and Nicolas Blanchemain
 INSERM U1008, Biomaterial Research Group, University Lille 2, France
- 11:30 24-3 **Keratinocyte and Fibroblast Adhesion on an Antibacterial Peptide Surface Coating**
A. Leong, M. Willcox
 School of Optometry and Vision Science, UNSW, Sydney, Australia
- 11:45 24-4 **Blood Compatible Antimicrobial Polymers with Degradable Backbone**
K. Fukushima, K. Kishi, Y. Inoue, C. Sato, A. Sasaki and M. Tanaka
 Department of Polymer Science and Engineering, Yamagata University, Japan
- 12:00 24-5 **Combinatorial Approach to Composition-Structure-Property Relationships in an Antibacterial Ag-Ti Thin Film**
Erik Unosson, Daniel Rodriguez, Ken Welch, Håkan Engqvist
 Department of Engineering Sciences, Uppsala University, Sweden
- 12:15 24-6 **Biofilms Bioreactors: An Infection concern in Medical Devices and biomaterials**
Steven L Percival, Rebecca Booth and Sean Kelly
 Institute of Ageing and Chronic Disease, University of Liverpool, UK

Materials for the Future: University of Liverpool Outreach Event Hall 1, 16:00 - 19:30

Chair: John Hunt, University of Liverpool

This outreach event will introduce a series of world-expert speakers who will present some of the issues for providing new materials, in a sustainable manner, to meet the needs of an ageing and ever-increasing population. The speakers will provide insight into how new research is providing diverse material solutions such as nano-medicines, stem cell therapies, and high performing next generation medical implants. Delegates will include the ESB 2014 delegation and then also University of Liverpool academics, alumni, industry partners, and civic leaders. The afternoon will showcase world-leading research from the University of Liverpool. There will be a series of talks from:

- 16:10 **Anthony Hollander**, University of Liverpool
- 16:25 **Steve Rannard**, University of Liverpool
- 16:40 **Chris Sutcliffe**, University of Liverpool
- 16:55 **Raphael Levy**, University of Liverpool
- 17:40 **Stephen Minger**, GE Healthcare
- 18:05 **Molly Shoichet**, University of Toronto
- 18:30 **Joachim Kohn**, Rutgers University
- 18:55 **David Williams**, Wake Forest Institute of Regenerative Medicine

Biomaterials V Room 3, 16:00 - 18:00

Chairs: James Anderson, Case Western Reserve University
Veronique Migonney, Université Paris XIII
Gloria Huerta-Angeles, Contipro Pharma

- 16:00 26-1 **Formation of Multicellular Spheroids on Arrayed Microwells with Microstructure**
Masahito Ban, Yuuya Kogi
Graduate School, Nippon Institute of Technology, Japan
- 16:15 26-2 **The Role of CD68-Positive Macrophages in the Biocompatibility of Biomaterials a Peritoneal Adhesion Prevention Model**
Christoph Brochhausen, *Volker H. Schmitt*, *Andreas Mamilos*, *Constanze N. E. Planck*, *Bernhard Krämer*, *Taufiek K. Rajab*, *Helmut Hierlemann*, *Heinrich Planck*, *C. James Kirkpatrick*
Institute of Pathology, University Medical Centre Mainz, Germany
- 16:30 26-3 **Swelling Gradients of Multilayers Mediate Directional Cell Migration**
Lulu Han, *Zhengwei Mao*, *Jindan Wu*, *Yang Guo*, *Tanchen Ren*, *Changyou Gao*
MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Zhejiang University, China
- 16:45 26-4 **Improvement of Graphene Nanoplatelet Biocompatibility by Surface Oxidation**
Artur Pinto, *Carolina Gonçalves*, *Daniela Sousa*, *Agostinho Moreira*, *Inês Gonçalves*, *Fernão Magalhães*
LEPABE, Faculdade de Engenharia, Universidade do Porto, Portugal
- 17:00 26-5 **Ibuprofen-Loaded Scaffolds for Spinal Cord Injury Regeneration – Targeting RhoA at the Lesion Site**
Liliana R Pires, *Cátia DF Lopes*, *Daniela N Rocha*, *Luigi Ambrosio*, *Mónica M Sousa*, *Ana Paula Pêgo*
INEB – Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- 17:15 26-6 **A Role for Platelet CD154 in the Foreign Body Reaction to Biomaterial**
Annabelle Tanga, *Sébastien Lepreux*, *Julien Villeneuve*, *Nelly Bordeau*, *Christian Combe*, *Alexis Desmoulière*, *Shahram Ghanaati*, *Jean Ripoche*
INSERM U1026, Bordeaux University, France
- 17:30 26-7 **The Mechanical Behavior and Biocompatibility of Polymer Blends for Patent Ductus Arteriosus (PDA) Occlusion Device**
Ying Ying Huang, *Yee Shan Wong* and *Subbu S. Venkatraman*
School of Materials Science and Engineering, Nanyang Technological University, Singapore
- 17:45 26-8 **Hydrolytic and Oxidative Degradation of Electrospun Supramolecular Biomaterials: In Vitro Degradation Pathways**
M. Brugmans, *S. Sontjens*, *M. Rubbens*, *A. Nandakumar*, *A. Bosman*, *T. Mes*, *H. Janssen*, *C. Bouten*, *F. Baaijens* and *A. Driessen-Mol*
Xeltis B.V., Eindhoven, The Netherlands

European Orthopaedic Research Society Symposium Room 11, 16:00 - 18:00

Chairs: Geoff Richards, AO Foundation
Thomas Miramond, Biomatlante
Sujit Kootala, Uppsala University

- 16:00 27-1 **Incorporation of RANKL Promotes Osteoclast Formation and Osteoclast Activity on β -TCP Ceramics**
J. Choy, *C.E. Albers*, *K.A. Siebenrock*, *S. Dolder*, *W. Hofstetter*, *F.M. Klenke*
Department of Clinical Research, University of Bern, Switzerland
- 16:15 27-2 **Calcium Phosphate Graft Substitute: When the Impact of Innovation is in the Form Rather Than Content**
Francisco Braga, *Antonio Carlos da Silva*, *Sérgio Allegrini*, *Cyro Ottoni*
CCTM/IPEN, CNEN, Brazil

- 16:30 27-3 **EPA-Coated Implants Promote Osteoconduction in White New Zealand Rabbits**
Ammar Mustafa, Christie Lung, Jukka Matinlinna
ISF Consultancy Hospital (Lekhwiya), Doha, Qatar
- 16:45 27-4 **Tailored Ca²⁺ Release in Hybrid Fibrous Scaffolds for Efficient Osteo- and Angiogenesis**
Oscar Castaño, Nadège Sachot, Elena Xuriguera, Elisabeth Engel, Josep A. Planell, Jeong-Hui Park, Guang-Zhen Jin, Tae-Hyun Kim, Joong-Hyun Kim and Hae-Won Kim
Institute for Bioengineering of Catalonia, Barcelona, Spain
- 17:00 27-5 **The Wear and Biological Activity of Antioxidant UHMWPEs in Total Hip Replacements**
Nic Gowland, Sophie Williams, John Fisher, Joanne L Tipper
Institute of Medical & Biological Engineering, University of Leeds, UK
- 17:15 27-6 **Chitosan-Hyaluronic Acid Based Porous Scaffold for Bone Regeneration**
Jing Jing, Jérôme Josse, Céline Mongaret, Saad Mechiche-Alami, Romain Reynaud, Dominique Laurent-Maquin, Sophie C. Gangloff, Frédéric Velard and Halima Kerdjoudj
EA 4691 "Biomatériaux et inflammation en site osseux", Université de Reims Champagne-Ardenne, France
- 17:30 27-7 **Superficial Zn-Doping into Biomaterials is Better than Bulk Doping**
Yugin Qiao and Xuanyong Liu
State Key Laboratory of High Performance Ceramics and Superfine Microstructure, Shanghai Institute of Ceramics, China
- 17:45 27-8 **Assessment of the Biodegradability of Ultrafine PCL Fibers Reinforced Calcium Phosphate Cement**
Yi Zuo, Boyuan Yang, Fang Yang, Qin Zou, Jidong Li, *Yubao Li* and J.A.Jansen
Research Center for nano Biomaterials, Sichuan University, China

Drug Delivery III Room 1B, 16:00 - 18:00

- Chairs:** M Cristina Tanzi, Politecnico di Milano
Yan Yan Shery Huang, University of Cambridge
Alfredo Ronca, National Research Council of Italy
- 16:00 28-1 **Biocomposites Containing Collagen, D-Amino Acids and Phytosome Nanoparticles as Drug Carriers and Tissue Engineering Scaffolds**
Krishnamoorthy Ganesan, Thotappalli Parvathaleswara Sastry, Asit Baran Mandal and Mukesh Doble
CSIR-Central Leather Research Institute, Tamil Nadu, India
- 16:15 28-2 **Supramolecular Anticancer Nanostructures Formed via Self-Assembly of Curcumin Amphiphiles**
Koji Nagahama, Naho Oyama and Takayuki Kumano
Department of Nanobiochemistry, Konan University, Japan
- 16:30 28-3 **Silica/Collagen Nanocomposites for Local and Sustained Release of Therapeutic Biomolecules**
Xiaolin Wang, Christophe Hélaré and Thibaud Coradin
Sorbonne Université, Paris, France
- 16:45 28-4 **Biomimetic Thin Films as Reservoirs for BMP-2**
Flora Gilde, Raphael Guillot, Laure Fourel, Ofelia Maniti, Thomas Boudou, Corinne Albigès-Rizo and Catherine Picart
UMR 5628 (LMGP), Grenoble Institute of Technology, France
- 17:00 28-5 **Novel Tool in Nanomedicine: Completely Biocompatible and Biodegradable Superparamagnetic Hydroxyapatite Nanoparticles**
S. Panzeri, M. Montesi, M. Sandri, E. Savini, M. Iafisco, A. Adamiano, M. Ghetti, G. Cenacchi, A. Tampieri
Institute of Science and Technology for Ceramics, National Research Council, Faenza (RA), Italy
- 17:15 28-6 **Antioxidant Delivery for Inhibition of Angiogenesis**
Masaki Moriyama, Stéphanie Metzger, Martin Ehrbar, André J. van der Vlies, Hiroshi Uyama and Urara Hasegawa
Graduate School of Engineering, Osaka University, JAPAN
- 17:30 28-7 **Design of Biodegradable pH-Responsive Microgels as Targeted Drug Delivery System**
Miren K. Aiertza, Pablo Casuso, Adrián Pérez-San Vicente, Hans-Jürgen Grande, Germán Cabañero, Irida Loinaz and Damien Dupin
Biomaterials Unit, IK4-CIDETEC, Spain
- 17:45 28-8 **A Biotemplating Approach Using the Marine Diatom for Fabricating Drug Delivery Reservoirs**
J. Chao, Y. Lang, A. Abdul-Rahman, M. Biggs, A. Pandit
Network of Excellence for Functional Biomaterials (NFB), National University of Ireland, Galway, Ireland

Biomaterials VI Room 1C, 16:00 - 18:00

- Chairs:** Mario Barbosa, University of Porto
Paul Santerre, University of Toronto
Pedro Granja, University of Porto
- 16:00 29-1 **Effect of Mesoscale Structure on the Properties of Composite Scaffold: from Micro to Nano**
Limei Li, Yi Zuo, Jidong Li, and *Yubao Li*
Research Center for nano Biomaterials, Sichuan University, China
- 16:30 29-2 **Factors Influencing Injectability of Nano-Hydroxyapatite Paste: a Rheological Behaviour**
Yulia Ryabenkova, Guenter Moebus, Paul V Hatton, Cheryl A Miller
Department of Materials Science and Engineering, University of Sheffield, UK
- 16:45 29-3 **Designing Biodegradable and Biocompatible Crosslinked Film from Polycarbonate Urethane and Zwitterionic Polynorbornene as Cell Growth Substrate**
Yakai Feng, Musamir Khan, Juan Lv, Jing Yang and Gregory Tew
School of Chemical Engineering and Technology, Tianjin University, China

- 17:00 29-4 **Periodic Mesoporous Organosilica (PMO) Coatings for Biomedical Applications**
Natalja Wendt, Mandy Jahns, Nina Ehler, Sabrina Schlie, Boris Chichkov, Peter Behrens
 Institut für Anorganische Chemie, Leibniz Universität Hannover, Germany
- 17:15 29-5 **Polymer Based Scaffolds with Microwave Induced Porosity**
 Antonella Giuri, Vincenzo Maria De Benedictis, Maria Grazia Raucci, *Christian Demitri*, Alessandro Sannino
 Department of Engineering for Innovation, University of Salento, Lecce, Italy
- 17:30 29-6 **Fabrication of Carbonate Apatite Coated Calcite and its In Vivo Evaluation**
Kunio Ishikawa, Kanji Tsuru, Melvin L. Munar, Masako Fujioka-Kobayashi, Youji Miyamoto
 Department of Biomaterials/Faculty of Dental Science, Kyushu University, Japan
- 17:45 29-7 **Polysaccharide Based Nanocarriers for Antioxidants**
 Ornella Bossio, Laura G. Gómez-Mascaraque, Mar Fernández-Gutiérrez, Blanca Vázquez-Lasa, *Julio San Román*
 Institute of Polymer Science and Technology, CSIC, Madrid, Spain

Antimicrobials, Biofilms and Surfaces Symposium, part 3 Room 4, 16:00 - 18:00

Chairs: Steven Percival, Scapa Healthcare
 Kazuki Fukushima, Yamagata University
 Alma Akhmetova, Nazarbayev University

- 16:00 30-1 **Effect of Kassinin and Collagen Fibrils on Cell Spreading and De-adhesion Dynamics**
Edna George, Pradeep Kumar Singh, Samir Maji and Shamik Sen
 Department of Bioscience & Bioengineering, Indian Institute of Technology (IITB), India
- 16:15 30-2 **Fast Acting Antibacterial 45S5 Bioglass® Scaffolds Reinforced with Gelatin/Genipin for Bone Tissue Engineering**
Wei Li, Hui Wang, Seema Agarwal and Aldo Boccaccini
 Institute of Biomaterials, University of Erlangen-Nuremberg, Germany
- 16:30 30-3 **Living Biointerfaces Based on Non-Pathogenic Bacteria to Direct Cell Function**
 Aleixandre Rodrigo-Navarro, Patricia Rico, Anas Saadeddin, Andres J. Garcia, *Manuel Salmeron-Sanchez*
 Division of Biomedical Engineering, University of Glasgow, UK
- 16:45 30-4 **Self-Disinfecting Urinary Biomaterials: pH-Triggered Quinolone Release for Prevention of Catheter-Associated Urinary Tract Infections**
 Colin P. McCoy, *Nicola J. Irwin*, Christopher Brady, Louise Carson, David S. Jones, Sean P. Gorman
 School of Pharmacy, Queen's University Belfast, UK
- 17:00 30-5 **Apatite Promoting, Low Modulus Composite Bone Cements with Low Heat Generation upon Set and High Subsequent Antibacterial Release**
Muhammad Adnan Khan, Anne Young
 UCL, Eastman Dental Institute, London
- 17:15 30-6 **Toward Potent Antibiofilm Degradable Medical Devices: Generic Methodologies for the Surface Modification of Polylactide**
Benjamin Nottelet, Carla Sardo, Sarah El Habnoui, Xavier Garric, Vincent Darcos, Jean-Philippe Lavigne, Gennara Cavallaro and Jean Coudane
 Institute of Biomolecules Max Mousseron (IBMM - CNRS UMR 5247), Université Montpellier I, France
- 17:30 30-7 **Controlled Release of Gentamicin from Gold Nanocarriers**
 Stefano Perni and *Polina Prokopovich*
 School of Pharmacy and Pharmaceutical Sciences, Cardiff University, UK
- 17:45 30-8 **Plasma Nanofilm as Biocompatible and Antibacterial Coating for Biomaterials**
Michael Bergmann, Sebastian Lickert, Loic Ledernez, Gregory Dame and Gerald Urban
 Department of Microsystems Engineering, Albert-Ludwigs-University of Freiburg, Germany

Chairs: Paul Hatton, University of Sheffield
Maria Grazia Raucci, National Research Council of Italy
Marco Lopez, University of Marburg

- 09:00 31-1 **Fluoride-Containing Bioactive Glasses – from Structure to Cell Compatibility**
D. S. Brauer, E. Gentleman, R. G. Hill and N. Karpukhina
Otto Schott Institute of Materials Research, Friedrich Schiller University Jena, Germany
- 09:15 31-2 **Atomic Structure of Mg-Based Metallic Glasses for Biomedicine**
Jamieson Christie
Department of Chemistry, University College London, K
- 09:30 31-3 **Bioactive Glass Nanoparticles for Therapeutic Applications and Incorporation into Hybrids for Bone Regeneration**
Sarah Greasley, Jesse V. Jokerst, Sanjiv S. Gambhir, Alexandra E. Porter, Julian R. Jones
Department of Materials, Imperial College London, UK
- 09:45 31-4 **Antitumor Efficacy of Radioactive Holmium (166Ho) Containing Silica Sol-gel Glass Granules on Osteosarcoma (MG-63) and Breast Cancer (MCF-7) Cells in Vitro**
Riku Alaranta, Jessica J Alm, Kaisa Lehtimäki, Heimo Ylänen, Tapio Ollonqvist and Hannu T Aro
Orthopaedic Research Unit, University of Turku, Finland
- 10:00 31-5 **Hybrid PLGA/Bioactive Glass Fiber Scaffolds for Bone Tissue Engineering**
Anne-Marie Haaparanta, Timo Lehtonen, Ville Ellä, Peter Uppstu, Markus Hannula, Ari Rosling and Minna Kellomäki
Biomaterials and Tissue Engineering Group, Tampere University of Technology, Finland
- 10:15 31-6 **Development of Novel 45S5 Bioglass® Scaffolds with Fibrous Surface Morphology using Electroflooding Technology for Bone Tissue Engineering**
Preethi Balasubramanian and Aldo R Boccaccini
Institute of Biomaterials, University of Erlangen-Nuremberg, Germany

Translational Research Symposium, part 1 Room 3, 09:00 - 10:30

Chairs: Marc Bohner, RMS Foundation
David Eglin, AO Foundation
Yves Bayon, Covidien

- 09:00 32-1 **Translation of Science to the Clinic: Where Preclinical Research Fits in the Model**
R. Geoff Richards
AO Research Institute Davos, Switzerland
- 09:30 32-2 **Innovation and Product Development in a Changing Regulatory and Socio-economical Environment**
Andrea Montali
DePuy Synthes Biomaterials R&D, Oberdorf, Switzerland
- 10:00 32-3 **Development of Dedicated Tools for Personalization of Medical Devices**
Lara Vigneron, Daniel Daryaie, Sebastian De Boodt, Lars Neumann
Biomedical Engineering Department, Materialise NV, Belgium

Tissue Engineering III Room 11, 09:00 - 10:30

Chairs: Guy Daculsi, University of Nantes
Pamela Habibovic, University of Twente
Nina Parmar, University College London

- 09:00 33-1 **Modulation of Cell Microenvironment Using Macromolecular Crowding: A Self Assembly Approach Towards In Vitro Organogenesis**
Abhigyan Satyam, Pramod Kumar, Xingliang Fan, Yury Rochev, Lokesh Joshi, Héctor Peinado, David Lyden, Benjamin Thomas, Brian Rodriguez, Michael Raghunath, Abhay Pandit and Dimitrios Zeugolis
Network of Excellence for Functional Biomaterials, National University of Ireland Galway, Ireland
- 09:15 33-2 **Collagen Plasma Treatment of Poly-(ether-ether)-ketone for Improved Cell Attachment**
Jessica S Hayes, Declan M Devine, Mary Murphy
Orthobiologics, Regenerative Medicine Institute, National University in Galway, Ireland
- 09:30 33-3 **PCL/HA Functional Gradient Scaffold for Osteochondral Tissue Engineering Applications**
Alessandra Marrella and Silvia Scaaglione
National Research Council (CNR), IEIT Institute, Italy
- 09:45 33-4 **Self-assembled Peptide Gels for Intervertebral Disc Tissue Engineering**
Simon Wan, Alberto Saiani, Stephen Richardson, Julie Gough
School of Materials, University of Manchester, UK
- 10:00 33-5 **Utilizing Multifunctional Alginate Scaffolds for the Regeneration of Skeletal Muscle Defects in a Rat Crush Trauma Model**
Taimoor Qazi, Matthias Pumberger, Tobias Winkler, Sven Geißler, David Mooney, Georg Duda
Julius Wolff Institute, Charité - Universitätsmedizin Berlin, Germany
- 10:15 33-6 **Engineering Hydrogel Polymer Networks for Cell Microencapsulation and Xenotransplantation**
Françoise Borcard, Redouan Mahou, Virginia Crivelli, Elisa Montanari, Raphael P. H. Meier, Yannick Müller, Annalena Bollinger, Carmen Gonelle-Gispert, Jörg D. Seebach, Raphael Plüss, Sandrine Gerber, Léo Bühler, Christine Wandrey
Institut d'Ingénierie Biologique et Institut des Sciences et Ingénierie Chimiques, Ecole Polytechnique Fédérale de Lausanne, Switzerland

Chairs: Keng-Liang Ou, Taipei Medical University
Serena Best, University of Cambridge
John Choy, University of Bern

- 09:00 34-1 **Development of Osteoconductive Organic-Inorganic Hybrid Materials Based on Calcium Silicates**
Chikara Ohtsuki, Toshiki Miyazaki and Masakazu Kawashita
Graduate School of Engineering, Nagoya University, Japan
- 09:15 34-2 **Formation of hybrid materials based on calcium phosphate deposit on carbon fiber scaffold**
Q. Picard, S. Delpeux, J. Chancolon, N. Rochet, F. Fayon, F. Warmont, S. Mikhalovski, S. Bonnamy
CRMD, CNRS, University of Orléans, France
- 09:30 34-3 **Strontium Ion Release from Bioactive Ti Alloys with Ca enriched-Surface Layer**
Seiji Yamaguchi, Tomiharu Matsushita and Tadashi Kokubo
Department of Biomedical Sciences, Chubu University, Japan
- 09:45 34-4 **Cell-to-cell Communications of Osteocytes with Bone Marrow Cells on Ceramic Biomaterials**
Miho Nakamura, Teuvo Hentunen, Jukka Vääräniemi, Jukka Salonen, Naoko Hori and Kimihiro Yamashita
Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University
- 10:00 34-5 **Critical Bone Defect Filling with Chitosan/Hydroxyapatite Hybrid Scaffolds in Rats**
Valérie Brun, Christine Guillaume, Julien Braux, Richard Gouron, Romuald Mentaverri, Saad Mechiche Alami, Sylvie Bouthors, Dominique Laurent-Maquin, Sophie C. Gangloff, Halima Kerdjoudj, Frédéric Velard
EA 4691 BIOS, University of Reims Champagne-Ardenne, France
- 10:15 34-6 **Fibrinogen Implants for Bone Regeneration: Short- and Long-Term In Vivo Responses**
Daniel M. Vasconcelos, Raquel M. Gonçalves, Susana G. Santos, Catarina R. Almeida, Inês Odila, Marta I. Oliveira, Nuno Neves, Andreia M. Silva, António C. Ribeiro, Elisabeth Seebach, Katharina L. Kynast, Thomas Niemietz, Wiltrud Richter, Meriem Lamghari, Mário A. Barbosa
INEB, University of Porto, Portugal

Stem Cells III Room 1C, 09:00 - 10:30

Chairs: Molly Shoichet, University of Toronto
Manuel Salmeron-Sanchez, University of Glasgow
Anna Guildford, University of Brighton

- 09:00 35-1 **Nanoscale Control of Mesenchymal Stem Cells**
Matthew J Dalby, P Monica Tsimbouri, Laura McNamara, Enateri Alakpa, Lesley-Anne Turner, Rebecca McMurray, Louisa CY Lee, Jingli Yang, Habib Nikukar, Gabriel Pemberton, Terje Sjoström, Peter Childs, Jugal Sahoo, Vineetha Jayawarna, Christopher West, Karl Burgess, Stuart Reid, Bo Su, Maggie Cusack, Nikolaj Gadegaard, Rein V Ulijn, RM Dominic Meek, Bruno Peault, Richard OC Oreffo
Centre for Cell Engineering, University of Glasgow, UK
- 09:30 35-2 **Photo-Crosslinkable Biopolymers Targeting Stem Cell Differentiation: the Candidature of Gelatin**
Ine Van Nieuwenhove, Sandra Van Vlierberghe, Winnok De Vos, Achim Salamon, Kirsten Peters and Peter Dubruel
Polymer Chemistry and Biomaterials Group, Ghent University, Belgium
- 09:45 35-3 **Investigating the "Bone-Shell Divide": Pearl Oyster Shell Topography as a Means of Directing Stem Cell Behaviour**
Enateri V. Alakpa, Matthew J. Dalby and Maggie Cusack
Centre for Cell Engineering, University of Glasgow, UK
- 10:00 35-4 **Generation of 3D Functional Microvascular Networks with Mural Cell-Like Human Mesenchymal Stem Cells in Microfluidic Systems**
S. Bersini, J. Jeon, RD Kamm and M. Moretti
IRCCS Istituto Ortopedico Galeazzi, Milan, Italy
- 10:15 35-5 **Atmospheric Pressure Plasma Treatment Increases the Attachment and Maturation of Human Pluripotent Stem Cell Derived Retinal Pigment Epithelial Cells on Biodegradable Polymeric Electrospun Scaffolds**
A. Sorkio, P. Porter, K. Juuti-Uusitalo, B. Meenan, H. Skottman and G. Burke
BioMediTech, University of Tampere, Finland

UKSB I: Welcome & President's Prize Room 4, 09:00 - 10:30

Chairs: Adrian Boyd, University of Ulster
Colin Scothford, University of Nottingham

- 09:00 **Welcome and Introduction to the UKSB Annual Meeting**
Sanjiv Deb
King's College London, UK
- 09:30 36-1 **The Drive for Simplicity in Delivering Cells to the Clinic - Clever Cells and Dumb Scaffolds**
Sheila MacNeil
Department of Materials Science & Engineering, University of Sheffield, UK

Chairs: Paul Hatton, University of Sheffield
 Maria Grazia Raucchi, National Research Council of Italy
 Muhammad Hasan, Dalhousie University

- 11:00 37-1 **Functionalising Natural Polymers with Alkoxysilane Coupling Agents for Tissue Engineering Applications**
Louise S Connell, Frederik Romer, Oliver Mahony, Mark E Smith, John V Hanna and Julian R Jones
 Department of Materials, Imperial College London, UK
- 11:15 37-2 **Composition-Structure-Property Relationships for Strontium Borate Glasses for Biomedical Applications**
Muhammad Sami Hasan and Daniel Boyd
 Department of Applied Oral Sciences, Dalhousie University, Halifax, NS, Canada
- 11:30 37-3 **Unravelling the Structure of Bioglass® through the Application of Diffraction Techniques**
Richard Martin
 School of Engineering & Aston Research Centre for Healthy Ageing, Aston University, UK
- 11:45 37-4 **Surface Functionalisation of Sol-Gel-Based Bioactive Glass Scaffolds for Drug Delivery**
A. Philippart, A. M. Beltrán, L. Pontiroli, C. Vitale-Brovarone, E. Spiecker and A. R. Boccaccini
 Institute of Biomaterials, University Erlangen-Nürnberg, Germany
- 12:00 37-5 **In Vitro Assessment of 3D Printed Wollastonite – Apatite-Based Glass Ceramic Biomaterials**
M.A. Lopez-Heredia, A. Zocca, C. Gomes, J. Günster, R. Gildenhaar, P. Colombo and C. Knabe-Ducheyne
 Dept. of Experimental Orofacial Medicine, Philipps University, Marburg, Germany
- 12:15 37-6 **Fabrication and Characterization of Electrospun PHB/PCL/Sol-gel Derived Glass Hybrid Scaffolds**
Yaping Ding, Teresa Müller, Judith A. Roether, Dirk W. Schubert, Aldo R. Boccaccini
 Institute of Polymer Materials, University of Erlangen-Nuremberg, Germany

Translational Research Symposium, part 2 Room 3, 11:00 - 12:30

Chairs: Marc Bohner, RMS Foundation
 David Eglin, AO Foundation
 Yves Bayon, Covidien

- 11:00 38-1 **Development of a Competitive Calcium Phosphate Cement in a Crowded Marketplace**
Philip Procter
 Medical Device Industry Consultant, Divonne les Bains, France
- 11:30 38-2 **The Commercial and Clinical Challenges and Opportunities for Advanced Materials in Regenerative Medicine**
Kevin M Shakesheff
 School of Pharmacy, University of Nottingham, UK
- 12:00 38-3 **Stratification and Personalisation of Biomaterials and Medical Devices in Musculoskeletal Disease**
John Fisher
 Institute of Medical and Biological Engineering, University of Leeds, UK

Tissue Engineering IV Room 11, 11:00 - 12:30

Chairs: Guy Daculsi, University of Nantes
 Pamela Habibovic, University of Twente
 Nina Parmar, University College London

- 11:00 39-1 **Layer-by-Layer Assembly of Collagen and Fibronectin for Tissue Engineering Applications**
Sara Mauquoy and Christine Dupont-Gillain
 Institute of Condensed Matter and Nanosciences (IMCN), Université Catholique de Louvain, Belgium
- 11:15 39-2 **Alginate-Silica Hybrid Hydrogels Through Covalent Coupling with APTES**
Yuliya Vueva, Siwei Li, Frederik Romer, John V. Hanna, Julian R. Jones
 Department of Materials, Imperial College London, UK
- 11:30 39-3 **The Effects of Current Density on the Morphology, Electrochemical and Biological Characteristics of Poly(3,4ethylenedioxythiophene): Poly(styrenesulfonate) (PEDOT-PSS) Conducting Films**
Catalina Vallejo-Giraldo, Abhay Pandit, Manus Jonathan Paul Biggs
 Network of Excellence for Functional Biomaterials (NFB), National University of Ireland, Galway, Ireland
- 11:45 39-4 **Biomimetic Scaffolds for Annulus Fibrosus Regeneration**
Sébastien B.G. Blanquer, Arjen W.H. Gebraad, Suvi P. Haimi, Susanna Miettinen, André A. Poot and Dirk W. Grijpma
 Dept. of Biomaterials Science and Technology, University of Twente, Enschede, The Netherlands
- 12:00 39-5 **Development of Bioamine Cross-linked Gellan Gum Hydrogels as Soft Scaffolds for Neural Tissue Engineering**
J. Koivisto, Sh. Teymouri, J.E. Parraga, T.O. Ihalaainen, K. Aalto-Setälä, M. Kellomäki
 Laboratory for Biomaterials and Tissue Engineering, Tampere University of Technology, Finland
- 12:15 39-6 **Thermoresponsive Self-Setting Calcium Phosphate Pastes for Minimally Invasive Surgery and Solid Freeform Fabrication**
Yassine Maazouz, Edgar Montufar, Julien Malbert, Maria-Pau Ginebra
 Dept. Materials Science and Metallurgical Engineering, Technical University of Catalonia, Barcelona, Spain

Chairs: Keng-Liang Ou, Taipei Medical University
Matteo Santin, University of Brighton
John Choy, University of Bern

- 11:00 40-1 **Cholecalciferol Synthesized After UV-Activation of 7-Dehydrocholesterol onto Titanium Implants Inhibits Osteoclastogenesis In Vitro**
María Satué, Joana M. Ramis and Marta Monjo
Group of Cell Therapy and Tissue Engineering, University of the Balearic Islands, Spain
- 11:15 40-2 **Mapping Phase Changes in Brushite Cements**
A. Bannerman, R.L. Williams and L.M. Grover
School of Chemical Engineering, University of Birmingham, UK
- 11:30 40-3 **Biomaterial Induced Bone Nodules without Medium Supplements**
S. Mechiche Alami, J. Hemmerlé, F. Boulmedais, J. Josse, P. Schaaf, S.C. Gangloff, F. Velard, D. Laurent-Maquin, H. Kerdjoudj
EA 4691 "Biomatériaux et inflammation en site osseux", Université de Reims Champagne-Ardenne, France
- 11:45 40-4 **Fibronectin Loaded Hydroxyapatite for Reduced Healing Time on Osteoporotic Rabbit Bone**
Javier Quintana-Plaza, Luis M. Rodríguez-Lorenzo
Polymeric nanomaterials and Biomaterials/ICTP-CSIC, Madrid, Spain
- 12:00 40-5 **Mineralization of Phosphate Prestructured Gelatine – Bulk Preparation and Characterization as Bone Substitute**
Benjamin Kruppke, Hartmut Worch and Thomas Hanke
Max Bergmann Center of Biomaterials, Technische Universität Dresden, Germany
- 12:15 40-6 **Adhesion, Growth and Differentiation of Pre-osteoblasts on Novel Porous Magnesia- and Yttria-Stabilized Zirconia Ceramics**
Chrystalleni Hadjicharalambous, Vladimir Promakhov, Svetlana Buyakova, Sergey Kulkov and Maria Chatzinikolaïdou
University of Crete, Dept. of Materials Science and Technology, Heraklion, Greece

Stem Cells IV Room 1C, 11:00 - 12:30

Chairs: John Kao, University of Wisconsin-Madison
Manuel Salmeron-Sanchez, University of Glasgow
Anna Guildford, University of Brighton

- 11:00 41-1 **Mesenchymal Stem Cell Response to Covalent Functionalized Recombinant Fibronectin Fragments onto New Titanium-Niobium-Hafnium Alloy**
C. Herranz-Díez, J. Guillem-Martí, F.J. Gil, J.M. Manero
Biomaterials, Biomechanics and Tissue Engineering Group, Technical University of Catalonia (UPC), Spain
- 11:15 41-2 **Combined Stimulation with Defined Extracellular Matrices and Pulsed Electrical Fields Enhance Osteogenic Differentiation of Human Mesenchymal Stem Cells**
R. Hess, P. Lee, A. Jaeschke, H. Neubert, T. Henker, V. Hintze, S. Moeller, M. Schnabelrauch, D. A. Hart, H.-P. Wiesmann, D. Scharnweber
Institute of Materials Science / Max Bergmann Center of Biomaterials, TU Dresden, Germany
- 11:30 41-3 **Influence of Surface Curvature on Human Mesenchymal Stromal Cell Migration and Differentiation**
M. Werner, S. Blanquer, S. Haimi, D. Grijpma, A. Petersen
Dept. of Biomaterials Science and Technology, University of Twente, Netherlands
- 11:45 41-4 **Zinc Oxide Nanorod Interaction with Rat Mesenchymal Stem Cells**
Giada Graziana Genchi, Antonella Rocca, Virgilio Mattoli, Barbara Mazzolai and Gianni Ciofani
Istituto Italiano di Tecnologia, Pontedera, Italy
- 12:00 41-5 **Engineering Substrate Topography and Chemistry to Control Mesenchymal Stem Cell Function**
Mohammed Khattak, John Hunt and Raechelle A. D'Sa
Centre for Materials and Structures, University of Liverpool, UK
- 12:15 41-6 **Gel Aspiration-Ejection Fabricates Anisotropic Injectable Dense Collagen Gels with Controlled Microstructure for Regenerative Medicine**
Showan N. Nazhat, Neysan Kamranpour, Mark James-Bhasin, Amir K. Miri, Chiara E. Ghezzi and Benedetto Marelli
Department of Mining and Materials Engineering, McGill University, Canada

UKSB II Room 4, 11:00 - 12:30

Chairs: Adrian Boyd, University of Ulster
Colin Scothford, University of Nottingham

- 11:00 42-1 **Harnessing Scanning Probe Nanolithographies for Cell and Molecular Biology**
Lu Shin Wong
Manchester Institute of Biotechnology, University of Manchester, UK
- 11:30 42-2 **Photochemical Functionalisation and Patterning of Diamond-Like-Carbon for Electronic Neural Interfaces**
James Dugan and Frederik Claeyssens
Department of Materials Science and Engineering, University of Sheffield, UK
- 11:45 42-3 **Impact Testing of Skin: Overcoming the Stratum Corneum Barrier for Microneedle Application**
Kikelomo Moronkeji, Simon Todd, Ahmed Elsheikh and Riaz Akhtar
School of Engineering, University of Liverpool, UK
- 12:00 42-4 **Exploring the Cell-Nanoneedle Interface**
Ciro Chiappini, Jonathan O. Martinez, Enrica De Rosa, Paola Campagnolo, Ennio Tasciotti, Molly M. Stevens
Department of Materials, Imperial College London, UK
- 12:15 42-5 **Strategies to Enhance the Cellular Response to Bioactive Surfaces**
L. Rutledge, L. Randolph, I. Mutreja, B. Meenan, A. Boyd
NIBEC, University of Ulster, Belfast, UK

Chairs: Aldo Boccaccini, University of Erlangen-Nuremberg
Gavin Jell, University College London
Kiruthika Natesan, Plymouth University

- 14:30 43-1 **Bone-like Apatite Deposition on Chemically Synthesized Collagen in Simulated Body Environment**
Toshiki Miyazaki, Jin Furui and Yuki Shirosaki
Graduate School of Life Science and Systems Engineering, Kyushu Institute of Technology, Japan
- 14:45 43-2 **In Vivo Study of Resorbable Phosphate Glass fibre Reinforced Composite Bone Fracture Repair Plates**
I. Ahmed, A. Qureshi, A.J. Parsons, C.A. Scotchford, B.E. Scammell, C.D. Rudd
Division of Materials, Mechanics and Structures, University of Nottingham, UK
- 15:00 43-3 **Marine Inspired Biosilica-Filled Hydrogels for Hard Tissue Repair**
Pamela Walsh, Susan Clarke, Iossif Strehin, Phillip Messersmith
School of Chemistry & Chemical Engineering, Queen's University, Belfast, UK
- 15:15 43-4 **Elucidating the Biological Role of Soluble Silicon in Early Bone Mineralisation**
Gurpreet Birdi, Richard M. Shelton, James Bowen, Pola Goldberg Oppenheimer and Liam M. Grover
School of Chemical Engineering, University of Birmingham, UK

Translational Research Symposium, part 3 Room 3, 14:30 - 15:30

Chairs: Marc Bohner, RMS Foundation
David Eglin, AO Foundation
Yves Bayon, Covidien

- 14:30 44-1 **Innovation and Product Development – Example of a leading medical device company**
Yves Bayon, Michel Thérin
Covidien – Sofradim Production, Trevoux, France
- 15:00 44-2 **Launching and Building a Science-Based Business**
Iain McDougall
Taragenyx Ltd, UK

Tissue Engineering V Room 11, 14:30 - 15:30

Chairs: Nicolas Blancheman, University of Lille 2
Wan Ting Sow, Nanyang Technological University
Anja Thiebes, RWTH Aachen

- 14:30 45-1 **Chitosan-Silica Hybrids for Biomedical Applications**
Christos Pandis, Estela Pérez Roman, Sara Trujillo, Christos Chatzimanolis-Moustakas, Sotiria Kripotou, Apostolos Kyritsis and José Luis Gómez Ribelles
Physics Department, National Technical University of Athens, Greece
- 14:45 45-2 **Triphasic Scaffolds for the Regeneration of the Bone-Ligament Interface**
G. Criscenti, A. Di Luca, A. Longoni, P. S. B. de Sousa and L. Moroni
Department of Tissue Regeneration, University of Twente, The Netherlands
- 15:00 45-3 **Cellular Responses to Elastin-Collagen Composite Scaffolds**
D. Bax, C. Grover, P. Lee, R. Farndale, A. Weiss, S. Best, R. Cameron
Department of Materials Science and Metallurgy, University of Cambridge, UK
- 15:15 45-4 **Chitosan-Siloxane Porous Scaffold for Nerve Reconstruction**
Yuki Shirosaki, Satoshi Hayakawa, Akiyoshi Osaka, José D. Santos, Ana C. Mauricio, Stefano Geuna
Frontier Research Academy for Young Researchers, Kyushu Institute of Technology, Japan

Clinical I Room 1B, 14:30 - 15:30

Chairs: Sheila McNeil, University of Sheffield
Assunta Borzacchiello, National Research Council of Italy
Pradip Paik, University of Hyderabad

- 14:30 46-1 **Nano-spun Meshes as Scaffolds for Regeneration and Stiffness Remodelling of Pelvic Floor Soft Tissues**
Mahshid Vashaghian, A. Ruiz Zapata, B. Zandie Doulabi, T.H. Smit
Obstetrics & Gynaecology, VU University Medical Center, Amsterdam, The Netherlands
- 14:45 46-2 **Coating of Polypropylene Mesh with Micro-Structured Gelatine as Potential Biomimetic Composite for Active Hernia Treatment**
Selestina Gorgieva, Maja Kaisersberger Vincek and Vanja Kokol
Institute for Engineering Materials and Design, University of Maribor, Slovenia
- 15:00 46-3 **Bioresorbable Polymer Based Novel Quick Vascular Closure Device (QVCD)**
Carsten Linti, Michael Doser, Sven Oberhoffner, Erhard Müller, Monika Renardy, Bernd Neumann, Hans-Peter Wendel
Institut für Textil- und Verfahrenstechnik Denkendorf, Germany
- 15:15 46-4 **Hydrophobically Modified, Cod-Derived Gelatins-Based Surgical Sealants Strongly Adhere onto Blood Vessel under Wet Condition**
Ryo Mizuta, Temmei Ito, Keiko Yoshizawa, Mikio Kajiyama, Toshimasa Akiyama, Katsuhiro Kamiya, Tetsushi Taguchi
Graduate School of life and Environmental Science, University of Tsukuba, Japan

Chairs: Matteo Santin, University of Brighton
 Raechelle D'Sa, University of Liverpool
 Elisabeth Engel, Institute for Bioengineering of Catalonia

- 14:30 47-1 **In situ-forming Pectin Hydrogels as Cell Delivery Systems**
SC Neves, DB Gomes, A Sousa, SJ Bidarra, P Petrini, L Moroni, CC Barrias, PL Granja
 INEB - Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- 14:45 47-2 **Double Layer Nanofiber Sandwich System in Effective Delivery of Growth Factors for Osteogenic Differentiation**
P. S. Gungor-Ozkerim, E. I. Bektas, A. S. Sarac, G.T. Kose, F.N. Kok
 Molecular Biology Genetics and Biotechnology Programme, Istanbul Technical University, Turkey
- 15:00 47-3 **Patient-Customizable Scaffolds with Nano/Microenvironments Rich in Human Platelet's Lysate and Marine-Origin Polysaccharides for Bone Formation Induction**
Sara M. Oliveira, Rui L. Reis, João F. Mano
 3B's Research Group – Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
- 15:15 47-4 **Effect of Cyclic Compression on Osteogenesis of Self-Assembled Collagen-Cell Seeded Microspheres**
Maryam Shariatzadeh, Cécile M. Perrault, Damien Lacroix
 Institute for in silico Medicine, University of Sheffield, UK

UKSB III: Alan Wilson prize Room 4, 14:30 - 15:30

Chairs: John Nicholson, University of Greenwich
 Riaz Akhtar, University of Liverpool

- 14:30 48-1 **The Effect of Extrinsic Tooth Bleaching Agents on Restorative Dental Materials: A Review**
Paul Hatton
 School of Clinical Dentistry, University of Sheffield, UK

Biomaterials X: Bioglass Hall 1, 16:00 - 18:00

Chairs: Aldo Boccaccini, University of Erlangen-Nuremberg
 Muhammad Hasan, Dalhousie University
 Marco Lopez, University of Marburg

- 16:00 49-1 **Ultra-thin Bioglass Fibres with Controlled Structures for Biomedical Applications**
Yangyang Li, Ding Zhao, Binbin Li, Qihong Zhang, Yike Fu, Mingwei Chang, Xiang Li
 Department of Materials Science and Engineering, Zhejiang University, China
- 16:15 49-2 **Serious Adverse Event of Woven Fabrics Made of Bioactive Glass Fibres of the Na₂O-K₂O-MgO-CaO-B₂O₃-P₂O₅-SiO₂ System in the Rabbit Spinal Fusion Model**
Janek P. Frantzen, Jessica J. Alm, Petteri Lankinen, Niko Moritz, Matias Røytta, Hannu T. Aro
 Orthopaedic Research Unit, University of Turku, Finland
- 16:30 49-3 **Towards Promoting Ability of Glass Ionomer Cements to Remineralise**
R. Albeshti, A. Bushby and N. Karpukhina
 Institute of Dentistry, Queen Mary University of London, UK
- 16:45 49-4 **The Retarding Effect of Zinc Oxide on Dissolution and Apatite Formation of a Fluoride Containing Bioactive Glass**
Xiaohui Chen, Priyen Shah, Mohammed Mneimne, Robert G. Hill and Natalia Karpukhina
 School of Dentistry, University of Manchester, UK
- 17:00 49-5 **Hypoxia Mimicking Glasses For Use As Chronic Wound Dressings**
AK Solanki, H Autefage, J Penide, F Quintero, J Pou, JR Jones, MM Stevens
 Department of Materials, Imperial College London, UK
- 17:15 49-6 **Bioactive glasses: Instructive Biomaterials to Control Cell Microenvironment**
Elisabeth Engel, Aitor Aguirre, Nadege Sachot, Oscar Castaño, Arlyng Gonzalez, Miguel A. Mateos-Timoneda, Soledad Pérez-Amodio, Josep A. Planell
 Biomaterials for Regenerative Therapies Group, Institute for Bioengineering of Catalonia, Barcelona, Spain
- 17:30 49-7 **Setting Kinetics and Micromechanical Properties of Flax Fibres Reinforced Restorative Glass Ionomers**
Ensanya A. Abou Neel, Wojciech Chrzanowski, Anne M. Young
 Division of Biomaterials, King Abdulaziz University, Jeddah, Saudi Arabia
- 17:45 49-8 **Hypoxia Mimicking Bioactive Glasses for Chronic Wound Healing**
Maria Azevedo, Siwei Li, Wai Ho, Alex Burns, Luara Schoenewolf, Chris Nayar and Gavin Jell
 Division of Surgery & Interventional Science, University College London, UK

Translational Research Symposium, part 4 Romo 3, 16:00 - 18:00

Chairs: Marc Bohner, RMS Foundation
 David Eglin, AO Foundation
 Yves Bayon, Covidien

- 16:00 50-1 **Non-Invasive and specific Attachment of Hernia Mesh by Click Chemistry**
R. Vestberg, M. Guerin, A. Radlovic, O. Lefranc, S. Ladet
 Covidien, Trévoux, France
- 16:15 50-2 **Tubular Compressed Collagen Scaffolds Cultured in a Novel Flow-Bioreactor System for Ureter/Urethra Tissue Engineering Application**
Elif Vardar, Eva-Maria Balet, Hans Mattias Larsson, Jeffrey A. Hubbell and Peter Frey
 Institute of Bioengineering, École Polytechnique Fédérale de Lausanne, Switzerland

- 16:30 50-3 **Making Medical Stent in the Way of Laser Spot Welding of Stainless Steel Wires L316**
Delaram Mansourian, Mahyar Fazeli and Jamshid Aghazadeh Mohandesi
Department of Material Science and Metallurgy Engineering, AmirKabir University of Technology, Iran
- 16:45 50-4 **Towards an Implantable Bioreactor: Synthesis and Surface Modification Strategy for a Soft Tissue Engineered Elastomer**
D-E. Mogosanu, J. Vanfleteren, P. Dubruel
Polymer Chemistry and Biomaterials Research Group, Ghent University, Belgium
- 17:00 50-5 **Development of an Original Model to Investigate Cell Communication in Bone Tissue Engineering**
A. Grémaré, A. Aussel, R. Bareille, J. Guerrero, J. Amedee, D. Le Nihouannen
Bioingénierie Tissulaire, U1026, University of Bordeaux, France
- 17:15 50-6 **Fabrication of Porous Titanium Scaffolds by Stack Sintering of Microporous Titanium Spheres Produced with Centrifugal Granulation Technology**
Hongjie Chen, Xiangdong Zhu, Yujia Fan, Xingdong Zhang
National Engineering Research Center for Biomaterials, Sichuan University, China
- 17:30 50-7 **Essential Model for Determining Biomaterial Attachment in Total Joint Replacement**
R. Bloebaum, N. Abdo, R. Olsen, A. Hofmann, J. Chalayan
George E. Wahlen Department of Veterans Affairs, Salt Lake City Health Care System, USA
- 17:45 50-8 **Incorporation of Polyelectrolyte Complexes into Alginate Hydrogels and their Effect on the Alginate Matrix**
R. Aston, T. Klein, G. Lawrie and L. Grøndahl
School of Chemistry and Molecular Biosciences, The University of Queensland, Australia

Tissue Engineering VI Room 11, 16:00 - 18:00

Chairs: Nicolas Blanchemain, University of Lille 2
David Shepherd, University of Cambridge
Anja Thiebes, RWTH Aachen

- 16:00 51-1 **Tissue Engineered Silk-fibroin Scaffolds for Meniscus Regeneration**
Joana Silva-Correia, Hélder Pereira, Le-Ping Yan, Ana Leite Oliveira, João Espregueira-Mendes, Joaquim Miguel Oliveira and Rui Luís Reis
3B's Research Group - Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
- 16:15 51-2 **Design Functionalized Polyesters and Widen the Applicability in Porous Degradable 3D Scaffolds**
Anna Finne-Wistrand, Jenny Undin and Ann-Christine Albertsson
Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Sweden
- 16:30 51-3 **Investigation of the Role of Shear Stress and Compression Stimuli on Cell Seeded PCL Scaffolds**
M. Brunelli, C. M. Perrault, D. Lacroix
Institute for in silico medicine, University of Sheffield, UK
- 16:45 51-4 **Engineered Dermal Micro-Tissues For Bottom-Up Tissue Engineering And TOC Applications**
A. Garziano, F. Urciuolo, G. Imparato, P. Netti
University of Naples Federico II, Italy
- 17:00 51-5 **Jet-Sprayed 3D Nanofibrillar Environment Decreases Myofibroblastic Activation**
Halima Rabehi, Romain Debret, Pascal Sommer, Dominique Sigaud-Roussel, Jérôme Sohier
Laboratory of Tissue Biology and Therapeutic Engineering (LBTI), CNRS, Lyon, France
- 17:15 51-6 **Fatty Tissue Equivalents – Build Up with Mature Adipocytes in a Gelatin Hydrogel**
Birgit Huber, Eva Hoch, Günter Tovar, Kirsten Borchers, Petra J. Kluger
Fraunhofer Institute for Interfacial Engineering and Biotechnology, Stuttgart, Germany
- 17:30 51-7 **Development of Photocrosslinkable Hyaluronan Hydrogels with Platelets lysates for Tissue Regeneration**
Ricardo Leandro Pires, Pedro S. Babo, Rui L. Reis and Manuela E. Gomes
3B's Research Group - Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
- 17:45 51-8 **Poly(vinyl alcohol) Physical Hydrogels as Functional, Biodegradable Matrices for Tissue Engineering**
Bettina E. B. Jensen, Katrine Edlund, Anton A. A. Smith, Leticia Hosta-Rigau, Brigitte Städler and Alexander N. Zelikin
Department of Chemistry, Aarhus University, Denmark

Clinical II Room 1B, 16:00 - 18:00

Chairs: Sheila McNeil, University of Sheffield
Assunta Borzacchiello, National Research Council of Italy
Jacob Brubert, University of Cambridge

- 16:00 52-1 **Calcium Concentrations for the Development of New Bioactive Dressings to Improve Skin Wound Healing**
Claudia Navarro, Soledad Pérez-Amodio, Josep A. Planell and Elisabeth Engel
Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain
- 16:15 52-2 **Swelling and Sealing Properties of a Novel Hemostatic Biomaterial**
Daniel Spazierer, Paul Slezak and Heinz Gulle
Baxter Innovations GmbH, Vienna, Austria
- 16:30 52-3 **A Pilot Renal Artery Embolization Study: Evaluation of "Imageable" Embolic Microspheres using Hybrid (Landrace Yorkshire) Farm Pigs**
Sharon Kehoe, Robert Abraham, Charles Daly, Daniel Boyd
ABK Biomedical Inc., Halifax NS, Canada
- 16:45 52-4 **Optimizing Properties of Bioadhesive Systems using Fermentation Derived Human Albumin**
Assunta Borzacchiello, Luisa Russo, Birgitte M. Malle, Sara Poulsen, Luigi Ambrosio
Institute of Polymers, Composites and Biomaterials, National Research Council, Naples, Italy

- 17:00 52-5 **Nanoengineered Biomaterials to Fight Gastric Infection: Exploring the Glycan-Adhesin Specific Interaction**
Inês C. Gonçalves, Ana M. S. Costa, A. Magalhães, Celso A. Reis, M. Cristina L. Martins
INEB - Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- 17:15 52-6 **Highly Selective Nanoparticles Based on Vitamin E Derivatives for the Treatment of Cancer**
Raquel Palao, Maria Rosa Aguilar, Mar Fernandez, Juan Parra, Carolina Sánchez, Ricardo Sanz, Julio San Roman
Department of Polymeric Nanomaterials and Biomaterials, ICTP-CSIC, Madrid, Spain
- 17:30 52-7 **Enhancing In Vitro and In Vivo Viability and Functionality of Pancreatic Islets Through a Gelatine-Based Hydrogel**
Serena Bertoldi, Simona Marzorati, Rita Nano, Lorenzo Piemonti and Silvia Faré
Dept. of Chemistry, Materials, and Chemical Engineering "G. Natta", Politecnico di Milano, Italy
- 17:45 52-8 **Long-term Degradation of Electrospun Poly(ϵ -caprolactone) Fibre Yarns In Vivo: A 12-month Study**
Lucy A Bosworth, Richard Wong, Marie A O'Brien, Jason K Wong, Duncan A McGruther and Sarah H Cartmell
School of Materials, University of Manchester, UK

Biomaterials XI: Hydrogels Room 1C, 16:00 - 18:00

Chairs: Luigi Ambrosio, National Research Council of Italy
Dirk Grijpma, University of Twente
Joana Magalhaes, Instituto de Salud Carlos III

- 16:00 53-1 **Design of Biomimetic Cell-Interactive Substrates using Hyaluronic Acid Hydrogels with Independently Tunable Stiffness and Biochemical Ligand Density**
Jing Jing, Marc R. Block and Rachel Auzély-Velty
Centre de Recherches sur les Macromolécules Végétales (CERMAV-CNRS), Grenoble, France
- 16:15 53-2 **Injectable Biocompatible and Biodegradable pH-Responsive Hollow Particle Gels Containing Poly(acrylic acid): The Effect of Copolymer Composition on Gel Properties**
S. Halacheva, D. Adlam, T. Freemont, J. Hoyland and B. Saunders
Institute for Materials Research and Innovation, University of Bolton, UK
- 16:30 53-3 **Dual Hydrogel System for Bioprinting of Strong Tissue Constructs**
Ferry Melchels, Wouter Dhert, Dietmar W. Huttmacher and Jos Malda
Department of Orthopaedics, University Medical Center Utrecht, The Netherlands
- 16:45 53-4 **Physical Hydrogels Based on Peptide Oligosaccharide Interaction**
Robert Wieduwild, Mikhail Tsurkan, Carsten Werner and Yixin Zhang
B CUBE Center for Molecular Bioengineering, Technische Universität Dresden, Germany
- 17:00 53-5 **The Physical Properties of Particles Dominate Cellular Uptake and Subsequent Influences on Cell Functions**
Zhenqwei Mao, Weijun Liu, Pengfei Jiang, Dahai Yu, Xiangyan Zhou, Changyou Gao
MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Zhejiang University, China
- 17:15 53-6 **The Size Effect of PLGA Microspheres on the Controlled-release of Fluorescein Isothiocyanate-Dextran as a Model for Targeting Synovial Macrophages in Vitro**
Rui Chen, Colette Redmond, John Innes and John A. Hunt
Clinical Engineering, Institute of Ageing and Chronic Disease, University of Liverpool, UK
- 17:30 53-7 **Hybrid Hydrogel/Fiber Construct for Neural Engineering Applications**
P.A. Wieringa, R. Pinho, S. Micera, R. van Wezel, L. Moroni
MIRA, University of Twente, The Netherlands
- 17:45 53-8 **Decellularized Matrix /Fibroin Injectable Hydrogels for Vascularized Adipose Tissue**
Alisan Kayabolen, Dilek Keskin, Ferit Avcu, Andac Aykan, Fatih Zor and Aysen Tezcaner
Department of Biomedical Engineering, Middle East Technical University, Turkey

UKSB IV Room 4, 16:00 - 18:00

Chairs: John Nicholson, University of Greenwich
Riaz Akhtar, University of Liverpool

- 16:00 54-1 **Synthetic Defensins: Novel Antibacterial Agents for Surface Attachment**
Felicity de Cogan, Richard Williams, Anna Peacock, Artemis Stamboulis, Liam Grover, Robert Scott & Ann Logan
School of Clinical and Experimental Medicine, University of Birmingham, UK
- 16:15 54-2 **Development of Decellularised conjunctiva for Ocular Surface Reconstruction**
Shivani Kasbekar, Rosalind Stewart, Stephen Kaye, Rachel Williams and Paul Rooney
Department of Eye and Vision Science, University of Liverpool, UK
- 16:30 54-3 **Highly Swollen and Compressible Photo-Activated Collagen Hydrogels**
Giuseppe Tronci, Colin A. Grant, Neil H. Thomson, Stephen J. Russell, David J. Wood
Nonwovens Research Group, University of Leeds, UK
- 16:45 54-4 **Mechanical and Cytotoxic Evaluation of a Novel Hydrogel with Potential Application as a Corneal Bandage**
Andrew Gallagher, Don Wellings and Rachel Williams
Department of Eye and Vision Science, University of Liverpool, UK
- 17:00 54-5 **Linking Antimicrobial Peptides with the Surface of Metallic Implants**
Zuzanna Trzcińska, Anna Peacock and Artemis Stamboulis
Biomaterials Group, University of Birmingham, UK
- 17:15 54-6 **UKSB AGM**
Sanjukta Deb
King's College London, UK

Chairs: Elizabeth Tanner, University of Glasgow
Claudia Loebel, AO Foundation
Monica Golda-Cepa, Jagiellonian University

- 09:00 55-1 **Reinforcement of Sol-Gel Processed Calcium Phosphate Cement using Functionalised CNTs**
K. Natesan, H. R. Le, C. Tredwin, R. Handy
School of Dentistry, University of Plymouth, UK
- 09:15 55-2 **Dynamics of Filopodium-Like Protrusion and Endothelial Cellular Motility on 1-D Extracellular Matrix Fibrils**
Niannan Xue, Cristina Bertulli, Amine Sadok, Yan Yan Shery Huang
The Institute of Cancer Research, London, UK
- 09:30 55-3 **The Importance of Interconnectivity for Cell Invasion and Percolation through Collagen Scaffolds**
J. Ashworth, P. Buxton, T. Hart, S. Best and R. Cameron
Cambridge Centre for Medical Materials, University of Cambridge, UK
- 09:45 55-4 **Novel Continuous Plastic Flow Synthesis of Phase Pure Nano-Sized Hydroxyapatite**
Aneela Anwar, Jawwad A. Darr
Clean Materials Technology Group, University College London, UK
- 10:00 55-5 **The Effects of Ascending and Descending Strain Rate on the Mechanical Properties of Canine Cranial Cruciate Ligaments**
Rosti Hama Rashid, Brendan Geraghty, Ahmed Elsheikh and Eithne Comerford
School of Engineering, University of Liverpool, UK

Bioactive Glass Symposium, part 1 Room 3, 09:00 - 10:30

Chairs: Julian Jones, Imperial College London
Richard Langford, University of Cambridge

- 09:00 56-1 **Larry's Influences: from Bioactive Glasses to Scaffolds for Tissue Engineering and Nanoparticles for Drug Delivery**
M. Vallet-Regí, A. Salinas and D. Arcos
Dpt. Química Inorgánica y Bioinorgánica, Universidad Complutense de Madrid, Spain
- 09:30 56-2 **Bioactive Glasses: from Hensch to Hybrids**
Julian R. Jones
Department of Materials, Imperial College London, UK
- 10:00 56-3 **Clinical Use of S53P4 Bioactive Glass in Neurosurgery – Case Reports of Tumor Surgery, Infected Cervical Spine and Mucopyelocoele of the Frontal Sinuses**
Janek Frantzén
Department of Neurosurgery, Turku University Hospital, Finland
- 10:15 56-4 **Bioactive Glass S53P4 in the Treatment of Osteomyelitis – Multicenter Study**
Nina Lindfors, Carlo Romano
Helsinki University Central Hospital, Finland

Biomaterials XII Room 11, 09:00 - 10:30

Chairs: James Kirkpatrick, University of Mainz
Giulia Gigliobianco, University of Sheffield
Gloria Huerta-Angeles, Contipro Pharma

- 09:00 57-1 **In Vivo and In Situ Bioprinting of Cells and Biomaterials to Guide Tissue Repair**
Virginie Keriquel, Sylvain Catros, Sophia Ziane, Reine Bareille, Murielle Rémy, Samantha Delmond, Benoit Rousseau, Joëlle Amédée, Fabien Guillemot and Jean-Christophe Fricain
Inserm U1026, Université Bordeaux Segalen, France
- 09:15 57-2 **In Vivo Evaluation of Bone Integration of Poly(Vinyl-Alcohol) Hydrogel Fibers for Ligament Reconstruction**
D. Moreau, A. Villain, M. Bachy, D.N. Ku, D. Hannouche, H. Petite and L. Corté
Centre des Matériaux Pierre-Marie Fourn, Mines Paristech, France
- 09:30 57-3 **Understanding Nuclear Deformation Capacity of Cancer Cells Thanks to Micropillared Surfaces**
Florent Badique, Melanie Eichhorn, Jürgen Rühe, Oswald Prucker, Jean-Noël Freund and Karine Anselme
Mulhouse Materials Science Institute (IS2M), Université de Haute-Alsace, France
- 09:45 57-4 **Fatigue Behaviour of Selective-Laser-Melted Nickel-Titanium Scaffolds**
Therese Bormann, Bert Müller, Waldemar Hoffmann, David Wendt and Michael de Wild
Institute of Medical and Analytical Technologies, University of Applied Sciences Northwestern Switzerland, Muttenz
- 10:00 57-5 **3D Printed Silica- Gelatin Hybrid Tissue Scaffolds**
Maria Nelson, Siwei Li, Oliver Mahony, Molly M. Stevens, Gowsihan Poologasundarampillai, Kamel Madi, Peter D. Lee, Julian R. Jones
Department of Materials, Imperial College London, UK
- 10:15 57-6 **Tailoring Crimp Patterns of Electrospun Fibers by Using Thermal Shrinkage**
H. Chen, D. Baptista, J. Crispin, D. Saris, H. Fernandes, C.A. van Blitterswijk, R. Truckenmuller, L. Moroni
Department of Tissue Regeneration, University of Twente, The Netherlands

Chairs: Matthew Dalby, University of Glasgow
Abhay Pandit, National University of Ireland Galway
Wan Ting Sow, Nanyang Technological University

- 09:00 58-1 **Real Time Analysis of the Enzymatic Digestion of Chondroitin Sulfate: Role of the Sulfation Pattern**
Carla Silva, Ramon Novoa-Carballal, Rui Reis and Iva Pashkuleva
3B's Research Group – Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
- 09:15 58-2 **Development and Characterisation of a Decellularised Bovine Osteochondral Biomaterial for Cartilage Repair**
Hazel Fermor, Serena Russell, Sophie Williams, John Fisher and Eileen Ingham
Faculty of Biological Sciences, University of Leeds, UK
- 09:30 58-3 **An Injectable Silk-in-Silk System for Enhanced Proteoglycan Production**
Sumit Murab, Akshay Shrivastava, Juhi Samal, Alok Ranjan Ray, Sourabh Ghosh, *Abhay Pandit*
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland
- 09:45 58-4 **Anatomically Shaped, Collagen-Fibre Reinforced Device for Meniscal Repair**
Jennifer Shepherd, Daniel Howard, Siddhartha Ghose, Simon Kew, John Wardale, Ruth Cameron, Serena Best
Department of Materials Science and Metallurgy, University of Cambridge, UK
- 10:00 58-5 **"Nonswellable" Hydrogel without Mechanical Hysteresis**
Hiroyuki Kamata, Ung-il Chung and Takamasa Sakai
Department of Bioengineering, University of Tokyo, Japan
- 10:15 58-6 **A Collagen-Based Multimodal Delivery System Provides Therapeutic Factors as well as Physical Support for Treatment of Spinal Cord Injury in the Rat**
R. Ronan, H. Kraskiewicz, B. Breen, T. Sargeant, A. Pandit, S. McMahon
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland

UKSB V Room 4, 09:00 - 10:30

Chairs: Julie Gough, University of Manchester
Raechelle D'Sa, University of Liverpool

- 09:00 59-1 **Characterising the Micro- and Nano-mechanical Properties of Ageing and Diseased Soft Tissues**
Riaz Akhtar
Centre for Materials and Structures, University of Liverpool, UK
- 09:30 59-2 **Nanotubular Titania topography combined with amorphous calcium phosphate chemistry induces direct osteoblastic differentiation in mesenchymal stem cells**
Robert McLister, Mura McCafferty, George Burke, Brian J. Meenan
Biomaterials and Tissue Engineering Group, University of Ulster, Belfast, UK
- 09:45 59-3 **Microwave-assisted Synthesis of Calcium Phosphate Nanobiomaterials with Controlled Morphology**
P.J.T Reardon, J. Huang, J. Tang
Department of Chemical Engineering and Mechanical Engineering, University College London, UK
- 10:00 59-4 **A Dual Porosity Construct for Osteochondral Modelling and Repair**
Alexander A. Popov, George Roberts, David M. Grant, Colin A. Scotchford and Virginie Sottile
Wolfson Centre for Stem Cells, Tissue Engineering & Modelling, University of Nottingham, UK
- 10:15 59-5 **Radiological Assessment of Bioengineered Bone in a Muscle Flap for Reconstruction of a Critical-Size Mandibular Defect**
Randa Al-Fotawei, Edward Odell, Kurt Naudi, Matthew J. Dalby, *K. Elizabeth Tanner*, J McMahon, Ashraf Ayoub
Glasgow Dental Hospital & School, UK

Chairs: Elizabeth Tanner, University of Glasgow
Claudia Loebel, AO Foundation
Monica Golda-Cepa, Jagiellonian University

- 11:00 60-1 **Enhanced Control of Stem Cell Responses by Sub-Micron Material Parameters**
John Hunt, Rui Chen Sandra Fawcett, Judith Curran
Centre for Materials and Structures, University of Liverpool, UK
- 11:15 60-2 **Synthesis, Properties and In Vitro Toxicity of Magnetic Ferrite Nanoparticles**
Juan Sojo, Pier Bombilli, Kareem Noris, Gema Gonzalez
Centro Ingeniería de Materiales y Nanotecnología, Caracas, Venezuela
- 11:30 60-3 **Osteogenic Micro-Nanopatterned Titania for Orthopaedics**
Laura E. McNamara, T Sjöström, P Herzyk, RMD Meek, B Su, MJ Dalby
Centre for Cell Engineering, University of Glasgow, UK
- 11:45 60-4 **Hydrogel-Based Injectable Systems for the Local Delivery of Sodium Alendronate - In Vitro Evaluation with Osteoblast- and Osteoclast-Like Cells**
Urszula Posadowska, Martin Parizek, Elena Filova, Krzysztof Pietryga, Lucie Bacakova, Elzbieta Pamula
Faculty of Materials Science and Ceramics, AGH – University of Science and Technology, Krakow, Poland
- 12:00 60-5 **Bio-Corrosion Behaviour of Chosen Magnesium Alloys from the Mg-Zn-Ca System**
Katarzyna Kubok and Lidia Litynska-Dobrzynska
Department of Functional and Structural Materials, Polish Academy of Sciences, Poland
- 12:15 60-6 **Biofunctionalization of CoCr Alloy for Bone Tissue RepARATION**
Virginia Paredes, Emiliano Salvagni, Enriquez Rodríguez, José M. Manero
Antonio Nariño University (UAN), Colombia

Bioactive Glass Symposium, part 2 Room 3, 11:00 - 12:30

Chairs: Julian Jones, Imperial College London
Richard Langford, University of Cambridge

- 11:00 61-1 **Bioactive Glasses to Stimulate Angiogenesis**
Alejandro Gorustovich, Aldo R. Boccaccini
Institute of Biomaterials, University of Erlangen-Nuremberg, Germany
- 11:15 61-2 **Porosity Engineering in Bioactive Glasses: a Sol-Gel Approach**
J. Soulié, J. Lao, E. Jallot, J.M. Nedelec
Laboratoire des Matériaux Inorganiques, Clermont Université, Clermont-Ferrand, France
- 11:30 61-3 **Bioactive Glass-Ionomer Cements for Bone Tissue Regeneration**
Paul V. Hatton, Altair Contreras, Felora Mirvakily, Yulia Ryabenkova, Ian Brook, Aileen Crawford, Robert Moorehead, Andrew Rawlinson, Christine Freeman, Ian M. Reaney and Cheryl Miller
Bioengineering & Health Technologies Research Group, University of Sheffield, UK
- 11:45 61-4 **Well Ordered Mesoporous Bioactive Glasses for Bone Tissue Engineering and Drug Delivery**
Chengtie Wu
State Key Laboratory of High Performance Ceramics and Superfine Microstructure, Shanghai, China
- 12:00 61-5 **Glass Fiber-Reinforced Composite Cranial Implant with Bioactive Glass**
Pekka K. Vallittu
Department of Biomaterials Science and Turku Clinical Biomaterials Centre, University of Turku, Finland
- 12:15 61-6 **Bioglass Transformations by Laser Assisted Techniques**
F. Lusquiños, J. del Val, R. Comesaña, F. Quintero, A. Riveiro, M. Boutinguiza, J.R. Jones, R.G. Hill, J. Pou
Applied Physics Department, Universidade de Vigo, Spain

Biomaterials XIII Room 11, 11:00 - 12:30

Chairs: James Kirkpatrick, University of Mainz
Damien Lacroix, University of Sheffield
Giulia Gigliobianco, University of Sheffield

- 11:00 62-1 **Cell Behaviour Affected by Properties of Electrospun Nanofibers**
Yan Wei, Wentao liu, Xuehui Zhang, Xuliang Deng
Department of Geriatric Dentistry, Peking University, China
- 11:30 62-2 **Two-Photon Polymerization as a High-Resolution Tool to Control Surface Structure of Polymeric Biomaterials at Micro- and Nanoscale**
David Barata, Paulo Dias, Clemens A. van Blitterswijk and Pamela Habibovic
Department of Tissue Regeneration, University of Twente, Enschede, The Netherlands
- 11:45 62-3 **Facile Photochemistry Enables Protein and Cell Micropatterning in Open and Closed Polymer Systems**
Esben Kjær Unmack Larsen, Morten Bo Mikkelsen and Niels B. Larsen
Department of Micro- and Nanotechnology, DTU Nanotech, Technical University of Denmark
- 12:00 62-4 **3D Plotting of Biopolymer-Based Hollow and Core/Shell Structures**
Ashwini Rahul Akkineni, Yongxiang Luo, Tilman Ahlfeld, Anja Lode, Michael Gelinsky
Centre for Translational Bone, Joint and Soft Tissue Research, Technische Universität Dresden, Germany
- 12:15 62-5 **Magnetic PCL-Based Nanocomposites for Soft/Hard Tissue Regeneration**
Ugo D'Amora, Teresa. Russo, Roberto De Santis, Antonio Gloria, Monica Sandri, Anna Tampieri, L. Ambrosio
Institute of Polymers, Composites and Biomaterials, National Research Council of Italy

Chairs: Matthew Dalby, University of Glasgow
David Shepherd, University of Cambridge
Kiruthika Natesan, Plymouth University

- 11:00 63-1 **Artificial Ligaments From Poly(Vinyl Alcohol) Hydrogel Fibers**
L. Corté, G. Zhang, F. Detrez, S. Cantournet, J.S. Bach and D.N. Ku
Centre des Matériaux Pierre-Marie Fourt, Mines-Paris Tech, France
- 11:15 63-2 **Bioactivity of Medium Chain Length Polyhydroxyalkanoate Scaffold for Soft Tissue-Engineering Applications**
Aitor Larrañaga, Jorge Fernández, Carmen Ronchel, José L. Adrio, Jose-Ramon Sarasua
Department of Mining-Metallurgy and Materials Science, Polymat, University of the Basque Country, Spain
- 11:30 63-3 **Bioinspired Composites: Link between Alignment Control, Platelets Content and Mechanical Properties**
Laetitia Galea, A. Studart, Thomas Graule and Marc Bohner
Skeletal Substitutes Group, RMS Foundation, Switzerland
- 11:45 63-4 **Development and Characterization of Bilayered Scaffolds Incorporated with Gold Nanoparticles as Potential Skin Substitutes**
Ömer Aktürk and Dilek Keskin
Department of Engineering Sciences, Middle East Technical University, Turkey
- 12:00 63-5 **Multi-Scale Geometric Control of Mechano-Transduction and Cell Behaviour Using Polymer Brushes**
John Connelly, Jenny Malmström, Duncan Sutherland and J. E. Gautrot
Institute of Bioengineering, Queen Mary University London, UK
- 12:15 63-6 **Is the Presence of Multinucleated Giant Cells Within the Implantation Bed of Natural-Based Biomaterials Physiological? Assessment of In Vitro and In Vivo Screening of Three Different Porcine Collagen Membranes by Means of Multichamber Three-Dimensional Systems**
Shahram Ghanaati, Carlos Mota, Mike Barbeck, Patrick Booms, Robert Sader, Clemens van Blitterswijk, Lorenzo Moroni, C James Kirkpatrick
Institute of Pathology, University Medical Center of the Johannes Gutenberg University Mainz, Langenbeckstraße 1, 55101 Mainz, Germany

UKSB VI Room 4, 11:00 - 12:30

Chairs: Julie Gough, University of Manchester
Raechelle D'Sa, University of Liverpool

- 11:00 64-1 **The Effect of a RF/DC Magnetron Sputtered Coating on the Dissolution Behaviour and Osteoblast Response to an Mg-Y-RE Alloy**
Natasha A Bhuiyan, Robert Thornton, Joseph Robson, Julie E Gough
Material Science Centre, University of Manchester, UK
- 11:15 64-2 **Novel Biomimetic Scaffolds for Osteochondral Repair**
Amy Prosser, Leander Poocha, Gerhard Hildebrand, Klaus Liefeth, Colin Scotchford, Virginie Sottile and David Grant
Division of Materials Mechanics and Structures, University of Nottingham, UK
- 11:30 64-3 **Investigation into the Ability to Accurately Mimic Natural Extracellular Matrix using Artificial Electrospun Scaffolds**
Kirstie Andrews
School of Engineering, Manchester Metropolitan University, UK
- 11:45 64-4 **Bioactive and Highly Porous Nanofibres via Solution Blow Spinning and their Formation into Macroporous Scaffolds**
Eudes Leannon, Ana Leticia Braz, Isaque Jerônimo, Aldo R. Boccaccini, Showan N. Nazhat, Eliton S. Medeiros, Jonny J. Blaker
School of Materials, Manchester University, UK
- 12:00 64-5 **UKSB Closing Ceremony**
Sanjukta Deb
King's College London, UK

Chairs: Abhay Pandit, National University of Ireland Galway
Adrian Boyd, University of Ulster
Jacob Brubert, University of Cambridge

- 14:30 65-1 **In Vitro Bioactivity and Cell Differentiation Properties of Nanobioceramics with Different Nanostructure**
Cristian Covarrubias, Fabiola Arroyo, Consuelo Balanda, Isabel Celhay, Juan P. Rodríguez, Ana M. Pino, Carla Urrea, Mario Díaz, Miguel Neira, Pablo Caviedes
Laboratorio Nanobiomateriales, Facultad de Odontología, Universidad de Chile
- 14:45 65-2 **The Modelling of Self-Inflating Tissue Expanders**
X. Min and J. T Czernuszka
Department of Materials, University of Oxford, UK
- 15:00 65-3 **Protein Nano-Carriers from Clicked Glycosaminoglycan Block Copolymers**
Ramon Novoa-Carballal, Carla Silva, Stephanie Möller, Matthias Schnabelrauch, Rui L. Reis and Iva Pashkuleva
3B's Research Group – Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal
- 15:15 65-4 **Treatment of a Degenerative/Pro-Inflammatory Intervertebral Disc Organ Culture with Chitosan/Poly-γ-Glutamic Acid Nanoparticles Carrying and Anti-Inflammatory Drug**
Graciosa Q. Teixeira, Catarina L. Pereira, Hans-Joachim Wilke, Anita Ignatius, Mário A. Barbosa, Cornelia Neidlinger-Wilke, Raquel Goncalves
Institute of Biomedical Engineering (INEB), Universidade do Porto, Portugal
- 15:30 65-5 **Detection of C-Reactive Protein using Highly Dispersible Gold Nanoparticles Bearing Phospholipid Block Copolymers**
Yasuhiko Iwasaki, Toshihiro Kimura, Masaki Orisaka, Hideya Kawasaki, Tatsuro Goda and Shin-ichi Yusa
Faculty of Chemistry, Kansai University, Japan
- 15:45 65-6 **Antibody Coated Microparticles to Fabricate Functional 3D Constructs in Combination with Cells**
C. A. Custódio, V. E. Santo, M.B. Oliveira, M. E. Gomes, R. L. Reis, J. F. Mano
3B's Research Group – Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal

Bioactive Glass Symposium, part 3 Room 3, 14:30 - 17:45

Chairs: Julian Jones, Imperial College London
Richard Langford, University of Cambridge

- 14:30 66-1 **Regulating Cellular Function Through Physicomechanical Engineering of the Nanobiointerface**
Manus Biggs, Shalom Wind, Matthew Dalby & Abhay Pandit
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland
- 15:00 66-2 **The Response of Mesenchymal Stromal Cells to Strontium-Substituted Bioactive Glasses**
M. Santocildes-Romero, P. Hatton, R. Goodchild, A. Crawford, I. Reaney and C. Miller
School of Clinical Dentistry, The University of Sheffield, UK
- 15:15 66-3 **Unsupervised Techniques Unexpectedly Highlight Steroid Biosynthesis in the Global Response of Human MSC to Strontium-Substituted Bioactive Glasses**
H. Autefage, E. Gentleman, E. Littmann, M. Hedegaard, T. von Erlach, M. D. O'Donnell, M. Hedegaard, D. Winkler, M. M. Stevens
Craniofacial Development and Stem Cell Biology, King's College London, UK
- 15:30 66-4 **Application of FIBSEM and XRM to Study the Occlusion of Dentine Tubules From a Calcium Sodium Phosphosilicate Bioactive Glass (NovaMin™)**
Richard Langford, Jonathan Earl and Arno Merkle
Cavendish Laboratory, University of Cambridge, UK
- 15:45 66-5 **Osteoblast-Like Cell Reactions to Soluble Silicate Ions Released from Bioactive Glass and Siloxane-Containing Vaterite**
Akiko Obata, Norihiko Iwanaga, Hirotaka Maeda and Toshihiro Kasuga
Graduate School of Engineering, Nagoya Institute of Technology, Japan
- 16:00 66-6 **Atomic-scale Models of the Water-Bioactive Glass Interaction**
Antonio Tilocca and Alastair N Cormack
Inamori School of Engineering, Alfred University, USA
- 16:15 66-7 **Applications of solid state NMR to the characterisation of bioactive glasses**
Z. Lin, Julian R Jones, John V Hanna and Mark E Smith
Department of Physics, University of Warwick, Coventry, UK
- 16:30 66-8 **Chloride Containing Bioactive Glasses**
Robert Hill, Natalia Karpukhina and Xiaojing Chen
Dental Physical Sciences, Barts and The London, UK
- 16:45 66-9 **Solid-State NMR Study on Strontium-Substituted 45S5 Bioglass**
Kie Fujikura, Natalia Karpukhina, Akiko Obata, Toshi Kasuga, Della S. Brauer, Robert G. Hill and Robert V. Law
Imperial College London, Department of Chemistry, UK
- 17:00 66-10 **Structural Evolution and Phase Formation During Synthesis of Phosphate-Containing Sol-Gel Derived Bioactive Calcium Silicate 58S Glasses**
John V. Hanna, B. Yu, Claudia Ionescu, Julian R. Jones and Mark E. Smith
Department of Physics, University of Warwick, Coventry, UK
- 17:15 66-11 **Nano/Micro Structured Bioglasses Synthesized via Sol-gel and Electrohydrodynamic (EHD) Approaches**
Yangyang Li, Ding Zhao, Binbin Li, Qihong Zhang, Yike Fu, Juan Wang, Mingwei Chang, Zhaohui Ren, Xiang Li
Department of Materials Science and Engineering, Zhejiang University, China

- 17:30 66-12 **A Unified In Vitro Evaluation for Apatite-Forming Ability of Bioactive Glasses and their Variants**
Anthony L. B. Maçon, Taek B. Kim, Esther Valliant, Katherine Goetschius, Richard Brow, Delbert Day, Alexander Hoppe, Aldo Boccaccini, Il-Yong Kim, Chikara Ohtsuki, Tadashi Kokubo, Akiyoshi Osaka, Maria Vallet-Regi, Daniel Arcos, Leandro Fraile, Antonio Salinas, Alexandra Teixeira, Yuliya Vueva, Rui Almeida, Marta Miola, Chiara Vitale-Brovarone, Enrica Verne and Julian Jones
 Department of Materials, Imperial College London, UK

Biomaterials XV Room 11, 14:30 - 16:00

Chairs: Nicholas Dunne, Queen's University Belfast
 Derfogail Delcassian, Imperial College London
 Damien Lacroix, University of Sheffield

- 14:30 67-1 **Role of Stromal Vascular Fraction from Adipose Tissue in Association with a Phosphocalcic Scaffold to Regenerate Bone in Irradiated Area**
Florent Espitalier, Audrey Théry, Pauline Bléry, Jérôme Guicheux, Paul Pilet, Sophie Sourice, Pierre Weiss, Olivier Malard
 INSERM U791, Center for Osteoarticular and Dental Tissue Engineering, University of Nantes, France
- 14:45 67-2 **Design of Stimuli-Responsive Film Trough Layer-by-Layer Assembly for the Control of Protein Adsorption**
A. Osypova, C.M. Pradier, C. Jérôme, J. Landoulsi, S. Demoustier-Champagne
 Institute of Condensed Matter and Nanoscience (IMCN), Université Catholique de Louvain (UCL), Belgium
- 15:00 67-3 **Tissue Engineering Creates New Basis for Scientific Research in Cell-Biomaterial Interaction**
Malgorzata Lewandowska-Szumieł, Slawomir Ruminski, Katarzyna Walenko, Barbara Ostrowska, Wojciech Swieszkowski
 Department of Histology and Embryology, Medical University of Warsaw, Poland
- 15:15 67-4 **Wear and Friction of PEEK and CFR-PEEK Materials for Cervical Total Disc Replacement Bearings**
Ksenija Vasiljeva, Phil Hyde, John Fisher, Richard Hall
 University of Leeds, UK
- 15:30 67-5 **Nanofiber-Based Biomaterials Used to Direct Cellular Responses Associated with Epithelial-Mesenchymal Transition**
Raquel C. Barros, Edith Gelens, Menno de Jong, Roel Kuijer, Theo G. van Kooten
 Department of Biomedical Engineering, University Medical Center Groningen, University of Groningen, The Netherlands
- 15:45 67-6 **Characterising the Effects of Different Sterilisation Techniques on Electrospun Fibre Scaffolds**
Lucy A Bosworth and Sarah H Cartmell
 School of Materials, The University of Manchester, UK

Bone V Room 4, 14:30 - 16:00

Chairs: John Nicholson, University of Greenwich
 Elisabeth Engel, Institute for Bioengineering of Catalonia
 Kambiz Farbod, Radboud University Medical Center

- 14:30 68-1 **Novel Electric Discharge Assisted Mechanical Milling method as a mean of biomaterials synthesis in the Al-Zr-O system**
M. Wyszomirska, A. Calka, D. Wexler
 Mechanical, Material & Mechatronic, University of Wollongong, Australia
- 14:45 68-2 **Biofabrication of Osteochondral Grafts Via 3D Printing of Cell-Laden Microcarriers in a Gelatin Methacrylamide/Gellan Gum Bioink**
Riccardo Levato, Jetze Visser, Josep A. Planell, Elisabeth Engel, Jos Malda, Miguel A. Mateos-Timoneda
 Institute for Bioengineering of Catalonia, Barcelona, Spain
- 15:00 68-3 **Controlled and Reliable Carbonation of Low Temperature Calcium Phosphates**
Anna Díez-Escudero, Montserrat Espanol, Yassine Maazouz and Maria-Pau Ginebra
 Department of Materials Science and Metallurgical Engineering, Technical University of Catalonia, Spain
- 15:15 68-4 **Characterization and Biocompatibility of a Collagen/Hydroxyapatite-Microsphere Composite Scaffold for Bone Regeneration**
Rahmat Cholas, Sanosh Kunjalukkal Padmanabhan, Francesca Gervaso, Gayatri Udayan, Graziana Monaco, Alessandro Sannino and Antonio Licciulli
 Department of Engineering for Innovation, University of Salento, Italy
- 15:30 68-5 **PEO Physicochemical Modification of Novel Low-modulus β -Ti Alloys Shows Comparable Cellular Behaviour to Commercial α - and ($\alpha+\beta$)-Ti Alloys**
Mehdi Golozar, Constantin-Edi Tanase, Roger A. Brooks and Serena M. Best
 Cambridge Centre for Medical Materials, University of Cambridge, UK
- 15:45 68-6 **Machining of Metallic Biomaterials: Comparison between Co-Cr-Mo and Ti-Al-Nb Alloys**
Timotius Pasang, Mamoru Takahashi, Daiki Shinohara, Patrick Conor, Kiyoshi Tanaka and Osamu Kamiya
 Department of Mechanical Engineering, AUT University, Auckland, New Zealand

Poster Presentation Programme

- P1 Mechanical Properties of Zirconia 3-Unit Fixed Dental Prostheses Machined on a CAD/CAM System**
Carlos Nelson Elias, Heraldo Elias Salomão dos Santos, Claudinei dos Santos
 Instituto Militar de Engenharia, Brazil
- P2 Nano-Crystallite TCP Synthesized by Mechanical Activation To Use Tissue Engineering**
Hassan Gheisari Dehsheikh, Ebrahim Karamian
 Department of Material Engineering, Islamic Azad University, Isfahan, Iran
- P3 Hyperbranched Poly(β -Amino Ester) for High Performance Gene Delivery**
Dezhong Zhou, Wenxin Wang
 Charles Institute of Dermatology, University College Dublin, Ireland
- P4 Optimisation of Macromolecular Crowding Conditions for Enhanced Extracellular Matrix Deposition *in vitro***
Diana Gaspar, Abhay Pandit, Dimitrios Zeugolis
 Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland
- P5 Enhanced Extracellular Matrix Deposition and Maintenance of Mesenchymal Stem Cell Phenotype *In Vitro* using Macromolecular Crowding and Low Oxygen Tension**
D. Cigognini, P. Kumar, A. Satyam, C. Sanz-Nogués, T. O'Brien, A. Pandit and D. Zeugolis
 Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland
- P6 Synthesis and characterization of novel bioglass-ceramic $\text{CaO-Na}_2\text{O-SiO}_2\text{-P}_2\text{O}_5\text{-ZrO}_2\text{-TCP}$ by sol-gel processing**
Parisa Eslami, Giovanni Baldi, Valentina Faso
 Ce. Ri. Col Research Center of Colorobbia Italia, Italy
- P7 WITHDRAWN**
- P8 Interconnected porous calcium phosphate forming cement consisting of α -TCP foam granules and calcium phosphate acidic solution**
Khairul Anuar Shariff, Kanji Tsuru, Kunio Ishikawa
 Department of Biomaterials, Kyushu University, Japan
- P9 Antithrombogenic Surface on Poly(ether ether ketone) Prepared by Self-initiated Photoinduced Graft Polymerization of 2-Methacryloyloxyethyl Phosphorylcholine**
Kazuhiko Ishihara, Masayuki Kyomoto, Tetsuji Yamaoka, Sachiro Kakinoki
 Department of Materials Engineering, The University of Tokyo, Japan
- P10 Development of bioengineered designer scaffolds for full thickness skin wound healing**
Naveen Kumar
 Division of Surgery, Indian Veterinary Research Institute, Uttar Pradesh, India
- P11 Synthesis and *In Vitro* Biocompatibility of Carbonated Hydroxyapatite for Bone Tissue Engineering Application**
Yanny M. Baba Ismail, Oana Bretcanu, Kenneth W. Dalgarno, Alicia J. El Haj
 Institute for Science and Technology in Medicine, Keele University, Stoke-on-Trent, UK
- P12 Modification of Magnesium Coated Titanium Surfaces to Control Its Corrosion Rate**
O. Mazmanoglu, S. Onder, F. N. Kok, K. Kazmanli, M. Urgan
 Molecular Biology Genetics and Biotechnology Programme, Istanbul Technical University, Turkey
- P13 Dip TIPS as a Novel Process for Preparation of Anisotropic Channeled Porous Polymer Scaffolds for Guided Tissue Engineering Applications**
Naresh Kasoji, Dana Kubies, Marta M. Kumorek, Lud'ka Machová, Jan Kríž, Daniel Jiráček, Eva Fabryová, František Rypáček
 Institute of Macromolecular Chemistry, Academy of Sciences of Czech Republic, Prague
- P14 Different cryogel architectures as basis for 3D cell culture of prostate cancer cells**
Anne Baecker, Bettina Goeppert, F.J. Gruhl
 Karlsruher Institute of Technology, Germany
- P15 Rapid screening of potential biomedical zirconium alloys with 1 wt. % alloy additions**
F.Y. Zhou, Y.F. Zheng
 Center for Biomedical Materials and Engineering, Harbin Engineering University, China
- P16 Iron Oxide Colloids as hyperthermia agents**
Paula Soares, Isabel Ferreira and João Paulo Borges
 Department of Materials Science, FCT-UNL, Caparica, Portugal
- P17 Biodegradable Shape Memory Polymer Composite for Endovascular Embolization**
Yee Shan Wong, Subbu S. Venkatraman, Kiang Hiong Tay, Wei Min Huang and William R. Birch
 School of Materials Science and Engineering, Nanyang Technological University, Singapore
- P18 Analysis of PVA- hydrogels loaded with propolis for burn healing application**
Renata N. Oliveira, Regis Rouze, Brid Quilty, Gloria D.A. Soares, Rossana M.S.M. Thiré and Garrett B. McGuinness
 Department of Materials and Metallurgical Engineering, Federal University of Rio de Janeiro, Brazil
- P19 Bone regeneration in human bone defect by octacalcium phosphate collagen composite**
Tadashi Kawai, Shinji Kamakura, Keiko Matsui, Yuji Tanuma, Seishi Echigo, Osamu Suzuki and Tetsu Takahashi
 Division of Oral and Maxillofacial Surgery, Tohoku University Graduate School of Dentistry, Japan
- P20 Biological performance of injectable octacalcium phosphate-hyaluronic acid composites on bone augmentation**
Kentaro Suzuki, Takahisa Anada, Tatsuya Miyazaki, Naohisa Miyatake, Masami Hosaka⁴ Hideki Imaizumi, Eiji Itoi and Osamu Suzuki
 Division of Craniofacial Function Engineering, Tohoku University Graduate School of Dentistry, Japan

- P21 Mathematical Design and Experimental Evaluation of Borate Based Glass Ionomer Cements (GICs): Towards Predicting Antibacterial Efficacy and Ion Release**
X.F. Zhang, H. O'Shea, D. Boyd
Department of Applied Oral Sciences, Dalhousie University, Canada
- P22 Pre-osteoblast cell responses on phosphate and calcium co-immobilized titanium**
Sunarso, Riki Toita, Kanji Tsuru, Kunio Ishikawa
Department of Biomaterials, Kyushu University, Japan
- P23 Nanohybrid Approach to Create Cell-Compatible Degradable Copolymer Thermogels as Cell Delivery Carriers**
Naho Oyama and Koji Nagahama
Department of Nanobiochemistry, Konan University, Japan
- P24 Self-assembly of PEI Modified Biodegradable Complex Micelles as Gene Transfer Vector for Proliferation of ECs**
Juan Lv, Jing Yang, Xuefang Hao and Yakai Feng
School of Chemical Engineering and Technology, Tianjin University, China
- P25 Ultrasonic non-invasive monitoring of the mechanical properties of collagen vascular scaffolds in bioreactors**
Bernard Drouin, Ramiro M. Irastorza and Diego Mantovani
Laboratory for Biomaterials and Bioengineering, Laval University, Quebec City, Canada
- P26 Scaffold and tissue engineering by self-assembly therapies for tendon repair**
Dimitrios Zeugolis
Network of Excellence for Functional Biomaterials (NFB), National University of Ireland, Galway
- P27 Characterization of PCL based nano/micro fibrous scaffold for Bone Tissue Engineering**
Izabella Rajzer, Elżbieta Menaszek
Department of Mechanical Engineering Fundamentals, University of Bielsko-Biała, Poland
- P28 Mechanism of Electrodeposition of Poly(Ethylene Glycol) to Titanium Surface**
Takao Hanawa, Osamu Fukushima, Yusuke Tsutsumi, Hisashi Doi and Maki Ashida
Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University, Japan
- P29 Effects of Combination of Biomaterial and Stem cell Implants on the Hard and Soft Tissue of Experimental Animals**
Mara Pilmane, Andrejs Skagers, Ilze Salma, Sandris Petronis, Dagnija Loca, Janis Locs
Institute of Anatomy and Anthropology, Riga Stradins University, Latvia
- P30 Several drugs and model molecules controlled release studies from nanometric vesicles of polymer-lipid complexes**
Virginia Saez-Martinez, Anisa Mahomed, Brian J. Tighe
Biomaterials Research Unit, Aston University, Birmingham, UK
- P31 Modification of PVC catheters with a binary graft of PEGMA and AAc to improve their biocompatibility**
L. Islas, G. Burillo
Instituto de Ciencias Nucleares, Universidad Nacional Autonoma de México
- P32 Antibiotic-loaded silica nanoparticles/collagen composite hydrogels with prolonged antimicrobial activity for wound infection prevention**
Christophe Hélyar, Gisela S. Alvarez, Andrea M. Mebert, Xiaolin Wang, Thibaud Coradin and Martin F. Desimone
Materials and Biology Team, University Pierre and Curie, Paris, France
- P33 Fibroin reinforced calcium phosphate cement**
Martha Geffers, Jürgen Groll, Uwe Gbureck
Department of Functional Materials in Medicine and Dentistry, University of Würzburg, Germany
- P34 Influence of heat treatment and additives of alkali substituted calcium phosphate cements on their properties**
Martha Geffers, Laura Straub, Jürgen Groll, Uwe Gbureck
Department of Functional Materials in Medicine and Dentistry, University of Würzburg, Germany
- P35 Development of an in situ culture-free screening test for the rapid detection of Staphylococcus aureus within healthcare environments**
Adam Le Gresley, Alex Sinclair, Lauren E. Mulcahy, Lynsey Geldeard Samerah Malik and Mark D. Fielder
Pharmacy and Chemistry, Kingston University, London, UK
- P36 New Technology Based on Combination of Cryogel and Nanoparticles for Wound Management**
Timur Saliev, Gulsim Kulsharova, Alma Akhmetova, Talgat Nurgozhin, Ray D.L. Whitby and Sergey Mikhaylovsky
School of Engineering, Nazarbayev University, Kazakhstan
- P37 Rapid Patterning of 1-D Collagenous Topography as an ECM Protein Fibril Platform for Image Cytometry**
Niannan Xue, Xia Li, Cristina Bertulli, Zhaoying Li, Atipat Patharagulpong, Amine Sadok, Yan Yan Shery Huang
Department of Engineering, University of Cambridge, UK
- P38 Control of Bone Conduction on Pure Titanium by Surface Modification**
Masato Ueda, Masahiko Ikeda, Richard Langford, Jeremy Skepper, Ruth E. Cameron and Serena M. Best
Faculty of Chemistry, Kansai University, Japan
- P39 Modification Of Electrospun Nanofibrous Scaffold By Ink-Jet Printing**
Izabella Rajzer, Monika Rom, Elżbieta Menaszek
Department of Mechanical Engineering Fundamentals, University of Bielsko-Biała, Poland
- P40 WITHDRAWN**
- P41 Chelate Bonding Mechanism of a Novel Magnesium Phosphate Bone Cement**
Theresa Christel, Martha Geffers, Susanne Christ, Jürgen Groll and Uwe Gbureck
Department for Functional Materials in Medicine and Dentistry, University of Würzburg, Germany
- P42 Biocompatibility and Solubility of Calcium Doped Magnesium Phosphate Cement Granules**
Theresa Christel, Martha Geffers, Susanne Christ, Uwe Klammert, Berthold Nies, Andreas Höß, Jürgen Groll and Uwe Gbureck
Department for Functional Materials in Medicine and Dentistry, University of Würzburg, Germany

- P43 Study and design of RGD-Self-assembling peptide hydrogels**
Deidda Graziano, Mitraki Anna
 Materials Science Department, University of Crete, Heraklion, Greece
- P44 Structure and Properties Study of Calcium Apatites**
Y. Gao, R.V. Law, N. Karpukhina, R.G. Hill
 Department of Chemistry, Imperial College London, UK
- P45 Development and study of poly(butylene succinate)/chitosan/hemp fiber fully biodegradable composites**
Z. Terzopoulou, V. Nikolaidis, D. Bikiaris, E. Athanassiadou, E. Papadopoulou
 Department of Chemistry, Aristotle University of Thessaloniki, Greece
- P46 Effect of Albumin Adsorption on MC3T3-E1 and RAW264.7 Cell Response to Hydroxyapatite and α -Alumina**
Masakazu Kawashita, Jumpei Hayashi, Tada-aki Kudo, Hiroyasu Kanetaka, Zhixia Li, Toshiki Miyazaki, Masami Hashimoto
 Graduate School of Biomedical Engineering, Tohoku University, Japan
- P47 New Insights into the Control of 3D Architecture and Porosity in Collagen Scaffolds for Tissue Engineering**
K. M. Pawelec, A. Husmann, S. Best, R. Cameron
 Cambridge Centre for Medical Materials, University of Cambridge, UK
- P48 Characterization and cytocompatibility of nanocellulose films**
K.Hua, D.O. Carlsson, M. Strømme, A. Mihranyan, N. Ferraz
 Nanotechnology and Functional Materials, Uppsala University, Sweden
- P49 L-Lactide, D-Lactide and ϵ -caprolactone or δ -valerolactone based terpolymers for application in the medical field**
J. Fernández, A. Larrañaga, A. Etxeberria and J. R. Sarasua
 Department of Mining-Metallurgy Engineering and Materials Science, University of the Basque Country, Bilbao, Spain
- P50 WITHDRAWN**
- P51 Ionic liquid-doped and *p*-NIPAAm-based temperature responsive copolymer: Extraordinary entrapping and releasing behaviors of BSA at 38-42 °C**
Jae-won Seo, Ueon Sang Shin
 Institute of Tissue Regeneration Engineering, Dankook University, South Korea
- P52 Synthesis of a Bifunctional Silver-containing Biocomposite**
Anna A. Ivanova, Roman A. Surmenev, Maria A. Surmeneva, Timur Mukhametkaliyev, Kateryna Loza, Oleg Prymak, Matthias Eppler
 Department of Theoretical and Experimental Physics, National Research Tomsk Polytechnic University, Russia
- P53 Osteoinduction and survival of human osteosarcoma MG-63 cells on nanoporous hydroxyapatite scaffolds**
M. Beaufils-Hugot, F. Burgio, S. Stevanovic, P. Chavanne, O. Braissant, P. Gruner, R. Schumacher, U. Piolet
 FHNW, University of Applied Sciences and Arts of Northwestern Switzerland, Muttenz
- P54 Protein Adsorption onto Polymer-based Nanocarriers for Vaccine Delivery**
Nitesh Kunda, Gillian Hutcheon and Imran Saleem
 School of Pharmacy and Biomolecular Sciences, Liverpool John Moores University, UK
- P55 Surface functionalization of electro-spun Poly(L)Lactic Acid scaffolds with heparin to induce angiogenesis**
Giulia Gigliobianco, Sabiniano Roman, Chuh K. Chong and Sheila MacNeil
 Kroto Research Institute, University of Sheffield, UK
- P56 Neuronal growth on nano-pillar substrates**
Nahoko Kasai, Rick Lu, Touichiro Goto, Yoshiaki Kashimura, Azusa Oshima and Koji Sumitomo
 NTT Basic Research Laboratories, Atsugi, Japan
- P57 Biodegradable and Bioadhesive Hemostatics Comprising Polymer Complex Gel and Chitosan**
Tomoko Ito, Masazumi Eriguchi and Yoshiyuki Koyama
 Japan Anti-tuberculosis Association, Shin-Yamanote Hospital, Japan
- P58 The Effect of Water Saturation on the Compressive Properties of Calcium Sulphate Dihydrate**
J Koh, A López, B Helgason and S Ferguson
 Institute for Biomechanics, ETH-Zürich, Switzerland
- P59 Flexural Properties of Calcium Sulphate Dihydrate and Dicalcium Phosphate Dihydrate: Potential Role of Degradation with Water Saturation**
J Koh, B Helgason and S Ferguson
 Institute for Biomechanics, ETH-Zürich, Switzerland
- P60 Osteoconductivity of Super Hydrophilic Valve Metals and Titanium Alloys**
Kensuke Kuroda and Masazumi Okido
 EcoTopia Science Institute, Nagoya University, Japan
- P61 WITHDRAWN**
- P62 Evaluation of Dense Collagen Matrices as Wound Dressing for the Treatment of Foot Diabetic Ulcers**
Christophe Hélar, Gervaise Mosser, Aicha Abed, Didier Letourneur, Liliane Louedec, Thibaud Coradin, Marie Madeleine Giraud-Guille and Anne Meddahi-Pellé
 Materials and Biology Team, University Pierre and Curie, Paris, France
- P63 Electrodeposition of Nanostructured Zinc Oxide on Zinc with Potential for Bioresorbable Medical Devices**
M. Alves, C. Santos, M. J. Carneizim and F. Montemero
 Instituto Superior Técnico, Universidade Técnica de Lisboa, Portugal
- P64 Mechanical Strength and Microstructure of Biomedical Beta-type Ti Alloy Subjected to Fine Particle Bombarding**
Toshikazu Akahori, Yurie Oguchi, Tomokazu Hattori, Hisao Fukui, and Mitsuo Niinomi
 Faculty of Science and Technology, Meijo University, Japan

- P65 Stoichiometric Control for Hydroxyapatite Thin Film Prepared by Pulsed Laser Deposition Technique**
Hiroaki Nishikawa, Ryota Yoshikawa
Faculty of Bio-Oriented Science and Technology, Kinki University, Japan
- P66 The Influence of PBS and Lactic acid on vacuum-sintered bodies of a novel apatite for artificial bone and tooth**
Kenichi Tamura and Tomohiro Uchino
College of Engineering, Nihon University, Japan
- P67 Sol-gel assisted preparation of collagen hydrolysate scaffold: A Novel biomaterial for the treatment of chronic wounds**
Sathesh Kumar Ramadass, Sathiamurthi Perumal and Balaraman Madhan
Central Leather Research Institute, Tamil Nadu, India
- P68 Stress and Deformation in a Sutured Tendon Repair; an *in silico* Model**
S D Rawson, L Margetts, J K F Wong and S H Cartmell
School of Materials, University of Manchester, UK
- P69 Chemically cross-linked peptide-based hydrogels with potential biomedical applications**
M.A. Elsayy, A. Smith, A.F. Miller and A. Saiani
School of Materials, University of Manchester, UK
- P70 Calcium phosphate spheres incorporated into PMMA cement for enhanced antibacterial properties**
Tao Qin, Alejandro López, Caroline Öhman, Håkan Engqvist, Cecilia Persson, Wei Xia
Department of Engineering Sciences, Uppsala University, Sweden
- P71 MP-SPR New characterization method for interactions and ultrathin films**
Annika Jokinen, Niko Granqvist, Willem M. Albers and Janusz Sadowski
BioNavis Ltd., Finland
- P72 A Dimensionless Number for Electrospinning**
William W. Sampson
School of Materials, University of Manchester, UK
- P73 Acidic pH resistance of grafted chitosan on dental implant**
Doris M. Campos, Bérengère Toury, Mélanie D'Almeida, Ghania N. Attik, Alice Ferrand, Pauline Renoud and Brigitte Grosgeat
UFR d'Odontologie, Université Claude Bernard Lyon, France.
- P74 Ex vivo osteo-chondral organ culture**
Andrea Schwab, Jenny W Reboredo, Heike Walles
Tissue Engineering & Regenerative Medicine, University Hospital Wuerzburg, Germany
- P75 3D powder printing of structured TCP/Alginate scaffolds for bone tissue engineering**
Miguel Castilho, Jorge Rodrigues, Inês Pires, Barbara Gouveia, Manuel Pereira, Claus Moseke, Jürgen Groll, Uwe Gbureck, Elke Vorndran
Instituto Superior Técnico, Universidade de Lisboa, Portugal
- P76 Surface modification of Ti-6Al-4V alloy controlling OCP nucleation by electron cyclotron resonance plasma oxidation**
Hiroshi Masumoto, Mayumi Oikawa, Yusuke Oori, Takahisa Anada, Osamu Suzuki and Keiichi Sasaki
Frontier Research Institute for Interdisciplinary Sciences, Tohoku University, Japan
- P77 Evaluation the Cellular Behavior on Poly Lactic-co-Glycolic Acid - Gelatin Scaffolds by Electrospinning Method**
Farnaz Ghorbani, Haniyeh Nojehdehyan, Ali Zamanian
Biomedical Engineering Department, Islamic Azad University, Tehran, Iran
- P78 Conducting Polymer Platform for Anti-Cancer Drug Delivery**
K. Krukiewicz, T. Jarosz, J.K. Zak, M. Łapkowski, P. Ruskowski, T. Bobkiewicz-Kozłowska, B. Bednarczyk-Cwynar
Department of Physical Chemistry and Technology of Polymers, Silesian University of Technology, Poland
- P79 Stability of self-assembled hyaluronan polymeric micelle cores in aqueous solutions and whole human blood**
Daniela Šmejkalová, Kristina Nešporová, Jana Šógorková, Pavlína Halamková, Jaroslav Novotný, Jakub Syrovátka, Gloria Huerta-Angeles
Contipro Pharma, Dolní Dobrouč, Czech Republic
- P80 Extracellular matrix proteins regulate Adipose Derived Mesenchymal Stem Cells and Amniotic Fluid Stem Cells attachment and proliferation: utility for tissue and organ regeneration**
Anna Bajek, Joanna Olkowska, Natalia Gurtowska, Tomasz Drewa
Department of Tissue Engineering, Nicolaus Copernicus University, Bydgoszcz, Poland
- P81 Development of a new biomaterial based on Hyaluronan and oleic acid for drug delivery applications**
Gloria Huerta-Angeles, Martin Bobek, Daniela Šmejkalová, Kristina Nešporová and Vladimír Velebný
Contipro Pharma, Dolní Dobrouč, Czech Republic
- P82 Imaging of Biofilm Removal on Titanium and Glass by Dental Instruments**
E. Pecheva, N. Vyas, R.L. Sammons and A.D. Walmsley
School of Dentistry, University of Birmingham, UK
- P83 Poly (ϵ -lysine) dendrons as modulators of quorum sensing in *Pseudomonas aeruginosa***
Rahaf Issa, Steve Meikle, Stuart James and Ian R. Cooper
School of Pharmacy and Biomolecular Sciences, University of Brighton, UK
- P84 Comparative Osteogenesis of Calcium Silicate Cement and Calcium Phosphate Cement**
Shinn-Jyh Ding and Shu-Ching Huang
Institute of Oral Science, Chung Shan Medical University, Taichung, Taiwan
- P85 A study on PLLA/MWCNT nanocomposites compatibilized with pyrene-end-functionalized PLLA**
I. Martínez de Arenaza, M. Obarzanek-Fojt, J. R. Sarasua, E. Meaurio, F. Meyer, J. M. Raquez, P. Dubois and A. Bruinink
Materials Biology Interactions, EMPA, St Gallen, Switzerland
- P86 Microgels Immobilizing Eudragit Nanoparticles for Indomethacin Release**
Mihaela Nicoleta Holban, Anca Niculina Cadinoiu, Elena Folescu and Vasile Burlui
Acad. Ion Haulica Research Institute, Apollonia University of Iasi, Romania

- P87 Design of Biomimetic Fibronectin Fragment Used in Multi-layer Film Coating for Tissue Engineering**
C. Dridj, B. Miladi, G. Bœuf, A. Elmarjou, S. Changotade, F. Poirier, D. Lutowski, A. Elm'selmi
Laboratoire de Biologie Moléculaire, Ecole de Biologie Industrielle, France
- P88 Effect of increasing alanine content in self-assembling FEK octapeptides**
Andrew Smith, Stephen Boothroyd, Aline F. Miller and Alberto Saiani
School of Materials and Manchester Institute of Biotechnology, University of Manchester, UK
- P89 Structural alterations in the dura mater after exposure to clinically relevant CoCr nanoparticles. An organ culture approach**
Papageorgiou Iraklis, Abberton Thomas, Fuller Martin, Tipper Joanne L, Fisher John, Ingham Eileen
Institute of Medical & Biological Engineering, University of Leeds, UK
- P90 New Materials with Antibacterial Action of Functionalized Au Nanoparticles and Ga³⁺ Ions**
Mario Kurtjak, Marija Vukomanović and Danilo Suvorov
Advanced Materials Department, Jožef Stefan Institute, Slovenia
- P91 Biomimetic mineralization of early caries lesions with a self-assembling peptide**
Sabrina Stevanovic, Lucy Kind, Iwona Dziadowiec, Bert Müller, Uwe Pieses
Institute of Chemistry and Bioanalytics, University of Applied Sciences and Arts Northwestern Switzerland
- P92 Bacterial Adhesion and Biofilm Formation Reduced by the Immobilization of hLf1-11 Peptide onto Titanium Surface: A Comparison Study between Direct and ATRP based Covalent Immobilization**
Maria Godoy-Gallardo, Carlos Mas-Moruno, Kai Yu, Jose M. Manero, Javier Gil, Jayachandran N. Kizhakkedathu, Daniel Rodríguez
Department of Material Science, Technical University of Catalonia, Spain
- P93 A Preliminary Examination of Composition-Property Relationships for Methotrexate-Loaded Germanium-Based Glass Ionomer Cements**
Lauren Kiri, Daniel Boyd
School of Biomedical Engineering, Dalhousie University, Canada
- P94 PEI – Starch Nanospheres for siRNA based Gene Silencing Therapy for Cancer**
Berke Bilgenur Kandemir, Bülent Özpolat, Gamze Torun Köse, Vasif Hasirci
Middle East Technical University, Department of Biotechnology, Ankara, Turkey
- P95 Intracellular delivery system based on acylated hyaluronan**
Kristina Nešporová, Jana Šógorková, Lucie Vištejnová, Daniela Šmejkalová, Hana Kolářová, Vladimír Velebný
Contipro Biotech, Czech Republic
- P96 In vivo Investigations of the Early Stages of Bone Healing with Microdialysis**
Yvonne Foerster, Claudia Rentsch, Stefan Kalkhof, Martin von Bergen, Stefan Rammelt
University Centre of Orthopaedics and Trauma Surgery, University Hospital Carl Gustav Carus, Dresden, Germany
- P97 Characterization of Oxygen Plasma-treated Dental All-Ceramic Zirconia**
Hsiang Kao, Chung-Kai Wei and Shinn-Jyh Ding
Institute of Oral Science, Chung Shan Medical University, Taichung, Taiwan
- P98 High throughput screening of hMSC response to algorithm generated micro-topographies**
Frits F.B. Hulshof, Bernke J. Papenburg, Roman K. Trückenmuller, M. Hulsman, Natalie Fekete, Shantanu Sing, Clemens A. van Blitterswijk, Anne E. Carpenter, Dimitrios Stamatialis, Jan de Boer
Department of Tissue regeneration, University of Twente, Enschede, The Netherlands
- P99 On the Biocompatibility of UV Pre-irradiated Hydrothermally Grown TiO₂-coatings**
Martina Lorenzetti, Giulia Bernardini, Katja Trinkaus, Iztok Dogsa, Thomas Luxbacher, Katrin Susanne Lips, Annalisa Santucci, Reinhard Schnettler, David Stopar, Saša Novak and Spomenka Kobe
Department of Nanostructured Materials, Jožef Stefan Institute, Ljubljana, Slovenia
- P100 Fabrication of Tissue Engineering Scaffolds from Poly(ester-anhydride) by Projection Stereolithography**
Harri Korhonen, Pekka Lehtinen, Jouni Partanen, Jukka Seppälä
Laboratory of Polymer Technology, Aalto University, Finland
- P101 Immobilization Strategies to Functionalize Tantalum Surfaces with Cell-Adhesive Peptides: Physicochemical and Biological Characterization**
Carlos Mas-Moruno, Beatriz Garrido, Daniel Rodríguez, Elisa Ruperez, F. Javier Gil
Biomaterials, Biomechanics and Tissue Engineering Group, Universitat Politècnica de Catalunya, Spain
- P102 Novel sol-gel synthesis of (P₂O₅)₅₀-(CaO)₃₀-(Na₂O)₁₅-(Fe₂O₃)₅ glasses for biomedical application**
Farzad Foroutan, Nora de Leeuw and Jonathan Knowles
Division of Biomaterials and Tissue Engineering, University College London, UK
- P103 Development of novel nanofunctionalised glass ionomer cements containing chlorhexidine-hexametaphosphate nanoparticles: mechanical properties and method of incorporation**
Candice A Bellis, James A Holder, Dominic J O'Sullivan, Michele E Barbour
Oral Nanoscience, UK Kempton
- P104 Evaluation of the effect of polymer content on drug release and mechanical strength of a Geopolymer ER Formulation for opioid drugs**
Bing Cai, Håkan Engqvist, Susanne Bredenberg
Division for Applied Materials Science, Uppsala University, Sweden
- P105 Poly(butylene succinate) nanocomposites containing strontium hydroxyapatite nanorods for tissue engineering applications**
M. Nerantzaki, Z. Terzopoulou, E. Roumeli, D. Papageorgiou, D. Bikiaris, J. Will, J. Hum, A. Hoppe, J.A. Roether, A.R. Boccaccini
Chemistry Department, Aristotle University of Thessaloniki, Greece

- P106 New N-(2-carboxybenzyl)chitosan hybrid biocomposites for scaffolds applications**
M. Nerantzaki, Z. Terzopoulou, M. Mavidou, D.N. Bikiaris, M.D. Anastasopoulou, M.A. Karakassides, A.R. Boccaccini
 Chemistry Department, Aristotle University of Thessaloniki, Greece
- P107 Release of Propranolol hydrochloride from Polyethyleneglycol Modified Lactone Polymers**
Sanja Asikainen, Minna Malin and Jukka Seppälä
 Research Group of Polymer Technology, Aalto University, Finland
- P108 Titanium oxide coated cobalt-chromium-molybdenum; improving the osteogenic response of mesenchymal stem cells *in vitro***
N Logan, A Cross, S Collins, A Trayner, I Parkin, L Bozec and P Brett
 Biomaterials and Tissue Engineering, University College London, UK
- P109 Autophagy Modification by Intracellular Controlled Release of Rapamycin**
Junpei Nagata, Makoto Matsui and Yasuhiko Tabata
 Department of Biomaterials, Kyoto University, Japan
- P110 Bioactive orthopaedic devices for the local delivery of Gentamicin Sulfate preventing nosocomial infections**
Loïc Pichavant, Hélène Carrié, Laurent Plawinski, Valérie Héroguez and Marie-Christine Durrieu
 Laboratoire de Chimie des Polymères Organiques, Université de Bordeaux, Pessac, France
- P111 Design of a new composite structure based on resorbable synthetic and natural polymers for anterior cruciate ligament reconstruction**
Coline Pinese, Xavier Garric, Benjamin Notellet, Jean Coudane, Christian Gagnieu
 Artificial Biopolymers department, Montpellier I University, France
- P112 Impact of silver-coated wound dressings on bacteria biofilm viability for the prevention of skin infections**
Federica Paladini, Cinzia Di Franco, Angelica Panico, Gaetano Scamarcio, Alessandro Sannino, Mauro Pollini
 Dhitech Scarl, Lecce, Italy
- P113 Characterization of Antibacterial Nano-Silver Coated Hydrogel Fibers for Biomedical Applications**
Riccardo Raho, Fiorella Anna Lombardi, Federica Paladini, Sandro Boccarella, Alessandro Sannino, Mauro Pollini
 Department of Engineering for Innovation, University of Salento, Lecce, Italy
- P114 Optimization of Silicone as Implant Material for the Application in the Middle Ear: Incorporation of Functionalized Nanoporous Silica Nanoparticles**
Tanja Heemeier, Mandy Jahns, Songül Noyun, Laura Doniga-Grivat, Silke Besdo, Peter Behrens
 Institute for Inorganic Chemistry, Leibniz University of Hannover, Germany
- P115 Temporary implant surfaces equipped with an anti-adhesive plasma fluorocarbon polymer film**
Birgit Finke, Holger Tetrich, Henrike Rebl, J. Barbara Nebe, Rainer Bader, Uwe Walschus, Michael Schlosser, Klaus-Dieter Weltmann, Jürgen Meichsner
 Leibniz Institute for Plasma Science and Technology, Greifswald, Germany
- P116 Biocompatible Conductive Coatings based on Carbon Nanotubes**
Niklas Burblies, Katharina Kranz, Athanasia Warnecke, Peter Behrens
 Institute of Inorganic Chemistry, Leibniz Universität Hannover, Germany
- P117 Installing multifunctionality on titanium with RGD-decorated polymeric nanocapsules: Towards new osteointegrative therapies**
Pau Rocas-Alonso, Mireia Hoyos-Nogués, Josep Rocas, Fernando Albericio, José M. Manero, Javier Gil, Carlos Mas-Moruno
 Institute for Research in Biomedicine, Barcelona, Spain
- P118 Improvement of Electrode Surfaces for Biomedical Applications by Nanoporous Platinum Coatings**
Kim D. Kreisköther, Nina Ehlert, Natalja Wendt, Hans-Christoph Schwarz, Athanasia Warnecke, Katharina Kranz, Peter Behrens
 Institute of Inorganic Chemistry, Leibniz Universität Hannover, Germany
- P119 Vancomycin loaded bioactive orthopaedic devices preventing infections**
Hélène Carrié, Loïc Pichavant, Laurent Plawinski, Gilles Amador, Valérie Héroguez and Marie-Christine Durrieu
 Laboratoire de Chimie des Polymères Organiques, Université de Bordeaux, Pessac, France
- P120 Amidation via DMTMM: A New and Efficient Method for Hyaluronan Biomaterials Preparation**
Matteo D'Este, Mauro Alini, David Eglin
 AO Research Institute Davos, Switzerland
- P121 Silver nano-coatings on silk sutures for the prevention of surgical infections**
De Simone Serena, Gallo Anna Lucia, Paladini Federica, Sannino Alessandro, Pollini Mauro
 Dhitech Scarl, Lecce, Italy
- P122 Functionalisation of polyurethane films using YIGSR poly(ϵ -lysine) linked dendrons to manipulate the human mesenchymal cell response**
Anna Guildford, Nicola Contessi, Mariagemiliana Dessi, Steve Meikle, Serena Bertoldi, Silvia Fare, Maria Cristina Tanzi and Matteo Santin
 School of Pharmacy and Biomolecular Sciences, University of Brighton, UK
- P123 WITHDRAWN**
- P124 Synthesis and Characterization of Chitosan/Hydroxyapatite Biocomposite Scaffolds for Potential Bone Repair Applications**
Vitor César Dumont, Nádia S. Vieira Capanema, Alexandra A. Piscitelli Mansur and Herman Sander Mansur
 Center of Nanoscience, Nanotechnology and Innovation-CeNano²I, Federal University of Minas Gerais, Brazil
- P125 Synthesis of morphology controlled calcium phosphate nanobiomaterials for biomedical applications**
P.J.T. Reardon, J. Huang, J. Tang
 Department of Chemical Engineering and Mechanical Engineering, University College London, UK

- P126 Dextran as a Versatile Scaffold for Hydrogel Formation with Hyaluronic Acid**
Nick Dibbert, Bastian Dieter, Gerald Dräger and Andreas Kirschning
 Institute of Organic Chemistry, Leibniz University Hannover, Germany
- P127 Adsorption of Col I on poly(NaSS) grafted Ti6Al4V surfaces improves MC3T3-E1 osteoblast-like cells mineralization**
Helena Felgueiras and Véronique Migonney
 Laboratory of Biomaterials and Specialty Polymers, Université Paris XIII, France
- P128 Enhancement of integrin-mediated cell attachment by pre-adsorbed model proteins on poly(NaSS)-functionalized Ti6Al4V substrates: a QCM-D study**
Helena Felgueiras, Sven Sommerfeld, N. Sanjeeva Murthy, Joachim Kohn and Véronique Migonney
 Laboratory of Biomaterials and Specialty Polymers, Université Paris XIII, France
- P129 Predicting Change in Constitutive Behaviour of Degrading Polymers**
Hassan Samami, Jingzhe Pan
 Department of Engineering, University of Leicester, UK
- P130 Nitric oxide releasing polyester blends for topical skin vasodilation**
Victor Baldim and Marcelo Ganzarolli de Oliveira
 Institute of Chemistry, University of Campinas, Brazil
- P131 Structural Integrity Assessment of a Polymer-based Knee Implant**
Y. Fong, P. Reed, F. Pierron and M. Browne
 Bioengineering Science Research Group, University of Southampton, United Kingdom
- P132 Fabrication of hydroxyapatite thin film with entirely c-plane surface**
Masanobu Kusunoki, Yasuhiro Sakoishi, Katsuya Asano, Naoki Fujita, Takayuki Makino, Daisuke Oka
 Faculty of Biology-Oriented Science and Technology, Kinki University, Japan
- P133 A Parametric Study of a Mathematic Model for Degradation of Bioresorbable Polymers**
X. Chen and J. Pan
 Department of Engineering, University of Leicester, UK
- P134 Patient Specific Implants Using a Novel Rapid Template Approach**
A. Chan, P. Boughton, J. van Gelder, N. Young and A. Ruys
 Biomedical Engineering, University of Sydney, Australia
- P135 Use of Ivory to Assess Composite Dentine Bonding**
Saad Liagat, Paul Ashley, Laurent Bozec, Anne Young
 Eastman Dental Institute, University College London, UK
- P136 Preparation of Porous Titanium-Polyglycolide Composites**
Nobuyuki Hayashi, Shun Kojima, Masato Ueda, Masahiko Ikeda, Kenji Doi, Kazuki Hanami, Shigeo Mori, Hisashi Kitagaki, Shuntaro Terauchi
 Graduate School of Science and Engineering, Kansai University, Japan
- P137 Mechanical Properties and Surface of Ultrafine Grained Titanium for Dental Implants**
Carlos Nelson Elias, Daniel J. Fernandes, Jochen Roestel
 Instituto Militar de Engenharia, Brazil
- P138 Preparation and Characterization of Novel Composite Agarose Films for Wound Healing**
Alma Akhmetova, Matthew Illsley, Timur Saliev, Talgat Nurgozhin, Sergey Mikhailovsky and Iain Allan
 Department of Translational Medicine, Longevity and Global Health, Nazarbayev University, Kazakhstan
- P139 New approaches for the local prevention and treatment of fragilized osseous sites using doped-calcium phosphate cements**
C. Mellier, V. Schnitzler, E. Verron, F. Fayon, C. Despas, A. Walcarius, N. Rochet, J.-C. Scimeca, O. Gauthier, J.-M. Boulter, B. Bujoli and P. Janvier
 Pres L'Unam, CNRS UMR 6230, Nantes, France
- P140 Robotic Deposition of 3D Scaffolds Using β -tricalcium Phosphates Inks for Bone Regeneration**
Raquel Costa Richard, Renata Nunes Oliveira, Rossana Mara da Silva Moreira Thiré
 Department of Materials Engineering, Federal University of Rio de Janeiro, Brazil
- P141 Evaluation of Bone Replacement Materials in a Rabbit Cranial Defect Model using MicroCT and Hard Tissue Histology**
Gerlind Schneider and Dirk Linde
 Department of Otorhinolaryngology, Friedrich Schiller University Hospital, Jena, Germany
- P142 A New Analytical Model of GAAS MESFET With Different Laws of Mobility**
Y. Saidi, Z. Fares
 Department of Physics, Mentouri University, Constantine, Algeria
- P143 Tailoring the Interfacial Adhesion of Anodised TiO₂ Nanotubes on Ti-6Al-4V Alloy for Medical Implants**
U. Danookdharree, H. R. Le, R. Handy and C. Tredwin
 School of Marine Science and Engineering, University of Plymouth, UK
- P144 Nano-sized α -tricalcium phosphate for bone cement**
L. Vecbiskena, L. Altomare, L. De Nardo, R. Chiesa
 Institute of Biomaterials and Biomechanics, Riga Technical University, Latvia
- P145 Single Cell Tracking of Haematopoietic Stem Cells in 3D Biomimetic Gradients**
Michael Ansorge, Jiranuwat Sapudom, Tilo Pompe
 Institute of Biochemistry, Universität Leipzig, Germany
- P146 Electrochemical dissolution of stainless steel endodontic files fractured in the middle and apical thirds of the root canal**
Caroline Amaral, Fabiola Ormiga and José Ponciano Gomes
 Department of Metallurgy and Materials, Federal University of Rio de Janeiro, Brazil

- P147 Photochemical nitric oxide release from a Flutamin derivative incorporated in Pluronic F127 hydrogel**
Patricia Taladriz-Blanco and Marcelo G. de Oliveira
 Institute of Chemistry, University of Campinas, Brazil
- P148 Electrospun Human Hair Keratin Matrices Affect Human Fibroblast Behavior Through Topographical Cues**
Wan Ting Sow and Kee Woei Ng
 School of Materials Science and Engineering, Nanyang Technological University, Singapore
- P149 Release Kinetics of Gentamicin, Moxifloxacin, Vancomycin, and Colistin from Gelatin Micro- and Nanospheres**
J. Song, J. Odekerken, D. Löwik, T. Welting, F. Yang, J. Jansen and S. Leeuwenburgh
 Department of Biomaterials, Radboud University Medical Centre, The Netherlands
- P150 Atmospheric Plasma Surface Modification of Electrospun Poly(L-Lactic Acid): Effect on Mat Properties and Cell Culturing**
Laura Calzà, Vittorio Colombo, Luisa Stella Dolci, Andrea Fiorani, Maria Letizia Focarete, Matteo Gherardi, Romolo Laurita, Anna Liguori, Santiago David Quiroga, Paolo Sanibondi
 Department of Industrial Engineering, Università di Bologna, Italy
- P151 Development and characterization of a tridimensional intestinal model to study protein drugs absorption**
Carla Pereira, Francisca Araújo, Pedro L. Granja, Bruno Sarmento
 Instituto de Engenharia Biomédica, University of Porto, Portugal
- P152 Antifouling coatings of poly(ethylene glycol) on titanium for dental implants**
Judit Buxadera-Palomero, Sergi Torrent, Cristina Calvo, F. Javier Gil, Cristina Canal, Daniel Rodríguez
 Biomaterials, Biomechanics and Tissue Engineering group, Technical University of Catalonia, Barcelona, Spain
- P153 Hierarchical Structure of Multicomponent Polysaccharide-Based ECM Mimetics**
Ortal Levi, Guy Hochbaum and Ronit Bitton
 Department of Chemical Engineering, Ben-Gurion University of the Negev, Israel
- P154 Scavenging effect of Trolox released from brushite cements**
Gemma Mestres, Carlos F Santos, Lars Engman, Cecilia Persson, Marjam Karlsson Ott
 Department of Engineering Sciences, Uppsala University, Sweden
- P155 Thermomechanical properties and bioactivity of silicone hybrids containing inorganic biomedical fillers**
I.-G. Athanasoulia, S.P. Vasilakos, P.A. Tarantili, Tr. Papadopoulos
 Dental School, University of Athens, Greece
- P156 Kartogenin Conjugated Chitosan-Nano/Microparticles for the Intra-Articular Osteoarthritis Treatment**
Mi Lan Kang, Ji Yun Ko, Ji Eun Kim, Gun Il Im
 Department of Orthopedics, Dongguk University, Ilsan Hospital, Korea
- P157 Composition-Property Relationships for Lanthanum-Borate Glasses**
K. O'Connell, H. O'Shea, Muhammad Hasan, D. Boyd
 Department of Biological Sciences, Cork Institute of Technology, Ireland
- P158 Osteogenic Differentiation of AdMSCs on 17 β -Estradiol Releasing Chitosan-Hydroxyapatite Scaffolds**
Gülseren İrmak, T. Tolga Demirtaş, Damla Altındal, Mert Çalış, Menemşe Gümüşderelioğlu
 Bioengineering Department, Hacettepe University, Turkey
- P159 Understanding the Physiochemical Interactions between Denture Adhesives and the aqueous phase**
S. Gill, B.J Tighe, N. Roohpour, C. Jeffrey
 Biomaterials Research Unit, Aston University, Birmingham, UK
- P160 New approach of biomaterial design to enhance osteogenesis at the interface bone/implant**
Ibrahim Bilem, Pascale Chevallier, Laurent Plawinski, Eli Sone, Gaétan Laroche, Marie-Christine Durrieu
 Laboratory of Surface Engineering, Laval University, Canada
- P161 Development of nanostructured silicone copolymers to deliver antimicrobials to treat human infected wounds**
S Finnegan, S Rimmer, S Macneil, S Percival
 Department of Chemistry, University of Sheffield, UK
- P162 Development of new approaches to fabricate scaffolds for deep zone engineered articular cartilage**
Anne Canning, Paul Roach, Ying Yang, James Richardson
 Institute of Science and technology, University of Keele, UK
- P163 Adhesives and their role in the reduction of HCAI, skin and wound infections**
Steven L Percival, Rebecca Booth and Sean Kelly
 Institute of Ageing and Chronic Disease, University of Liverpool, UK
- P164 The utilisation of poloxamer as a model to study the complexicity of biofilms and antimicrobial efficacy in biomaterials**
Steven L Percival, Rebecca Booth and Sean Kelly
 Institute of Ageing and Chronic Disease, University of Liverpool, UK
- P165 The use of the MBEC assay for quantitative and qualitative investigation of biofilm forming isolates isolated from biomaterials**
Rebecca Booth, Sean Kelly and Steven L Percival
 Scapa Healthcare, Manchester, UK
- P166 Physical and chemical characteristics of adhesives for application on the skin**
Sean Kelly, Rebecca Booth and Steven L Percival
 Scapa Healthcare, Manchester, UK
- P167 The role of adhesives in biofilm prevention**
Steven L Percival, Rebecca Booth and Sean Kelly
 Institute of Ageing and Chronic Disease, University of Liverpool, UK

- P168** **Silicone adhesives and their use in skin and wound care**
Sean Kelly, Rebecca Booth and Steven L Percival
Scapa Healthcare, Manchester, UK
- P169** **A Computer Model for Polymer Degradation in the Presence of Acidic Drug**
K. Sevim and J. Pan
Department of Engineering, University of Leicester, UK
- P170** **In vitro degradability, bioactivity and cell responses to mesoporous magnesium silicate for bone regeneration**
Jie Wei, Zhaoying Wu, Han Guo, Changsheng Liu
Key Laboratory for Ultrafine Materials, East China University of Science and Technology, P.R. China
- P171** **Macromolecular crowding maintains tenogenic phenotype ex vivo**
Kyriakos Spanoudes, Abhigyan Satyam, Abhay Pandit, Dimitrios Zeugolis
Network of Excellence in Functional Biomaterials, National University of Ireland, Galway
- P172** **Effect of cooling rates after casting and subsequent Solution Treatment on Microstructure and Mechanical Strength of Dental Silver Alloys with different Cu contents**
Tomoya Yasuda, Toshiyazu Akahori, Yushi Hoshiya, Tomokazu Hattori, Hisao Fukui
Graduate School of Science and Technology, Meijo University, Japan
- P173** **Change in Microstructure and Mechanical Strength of Substitution Material for Dental Precious Alloys Fabricated by Solidification under Various Conditions**
Yushi Hoshiya, Toshiyazu Akahori, Tomoya Yasuda, Tomokazu Hattori, Hisao Fukui
Graduate School of Science and Technology, Meijo University, Japan
- P174** **Morphological Control of Layered Double Hydroxide Crystals as Drug Carrier by Organic Molecules with Carboxyl Group**
Taishi Yokoi, Sota Terasaka and Masanobu Kamitakahara
Graduate School of Environmental Studies, Tohoku University, Japan
- P175** **Properties of β -TCP based Calcium Phosphate Cement using mechano-chemical process**
J. Y. Bae, Y. Ida, K. Sekine, F. Kawano and K. Hamada
Department of Biomaterials and Bioengineering, University of Tokushima, Japan
- P176** **Evaluation of osteoinductive properties of different combinations of macroporous biphasic ceramic (MBCP+™), simvastatin, total bone marrow cells and rhBMP-2 in a rat subcutaneous induced membranes model**
Erwan de Monès, Silke Schlaubitz, Reine Bareille, Chantal Bourget, Pascal Borget, Guy Daculsi, Marlène Durand, Jean-Christophe Fricain
Bioingénierie Tissulaire, Université Bordeaux, France
- P177** **Development and Characterization of Thermally Responsive PluronicF127-Chitosan-Kartogenin Conjugates Based Dual Drug Delivery System**
Mi Lan Kang, Ji Yun Ko, Ji Eun Kim, Gun Il Im
Department of Orthopedics, Dongguk University Ilsan Hospital, Korea
- P178** **Transduction of Tissue-specific Transcription Factor Protein as a Tool for Tissue Engineering**
Masayasu Mie, Shinya Hashimoto, Mami Kaneko and Eiry Kobatake
Department of Environmental Chemistry and Engineering, Tokyo Institute of Technology, Japan
- P179** **Construction of Multifunctional Proteins by Integration of Scaffolds and Growth Factors**
Eiry Kobatake and Masayasu Mie
Department of Environmental Chemistry and Engineering, Tokyo Institute of Technology, Japan
- P180** **Gel-in-Gel extrusion of cells for soft and hard tissue construction**
Erkan Türker Baran and Vasif Hasirci
Center of Excellence in Biomaterials and Tissue Engineering, Middle East Technical University, Turkey
- P181** **Real-time monitoring of chondrocyte activity by electrical impedance measurement**
R. Mizota, Y. Morita and E. Nakamachi
Graduate School of Life and Medical Sciences, Doshisha University, Japan
- P182** **Dynamic Hardness Evaluation of Two Phases of Au-xPt-8Nb Alloys for MRI-artifact-free Biomedical Devices**
S. Inui, E. Uyama, E. Honda and K. Hamada
Institute of Health Biosciences, University of Tokushima, Japan
- P183** **Electrospun fleeces fabricated from new biodegradable polyurethanes and evaluation of their use as tissue engineering scaffolds for adipose-derived stem cells**
Thorsten Laube, Alfred Gugerell, Ralf Wyrwa, Johanna Kober, Torsten Walter, Sylvia Nürnberger, Elke Grönniger, Simone Brönneke, Maike Keck, Matthias Schnabelrauch
Biomaterials Department, INNOVENT eV, Jena, Germany
- P184** **Design, Synthesis and Development of a Self-Assembled Polymeric Nanoparticle System for Gene Delivery**
Li-yen Wong, Ernst Wolvetang, Justin Cooper-White
Tissue Engineering and Microfluidics Laboratory, University of Queensland, Brisbane, Australia
- P185** **Biological Properties of an Acellular Xenogeneic Tendon Graft following Chemical and Irradiation Sterilisation**
J H Edwards, J Fisher and E Ingham
Institute of Medical and Biological Engineering, University of Leeds, UK
- P186** **Improved early cell adhesion on bioinert ceramics by alkaline phosphatase immobilization**
Alieh Aminian, Bahareh Shirzadi, Laura Treccani and Kuroschi Rezwan
Advanced Ceramics, University of Bremen, Germany
- P187** **Thermoresponsive Hydrophobic Copolymer Brush for Cell Separation by Multi-Step Temperature Change**
Kenichi Nagase, Yuri Hatakeyama, Tatsuya Shimizu, Katsuhisa Matsuura, Masayuki Yamato, Naoya Takeda, Teruo Okano
Tokyo Women's Medical University, Japan

- P188 A Novel Biological Polyester Based Wet Spun Scaffold for Bone Tissue Engineering**
Ayşe Selcen Alagoz, Jose Carlos Rodriguez-Cabello, Nesrin Hasirci, Vasif Hasirci
 Department of Biological Sciences, Middle Eastern Technical University, Turkey
- P189 Development of novel hydroxyapatite-chitosan porous 3D scaffolds for biomedical applications**
Dimitris Tsiourvas and Triantafillos Papadopoulos
 Department of Biomaterials, School of Dentistry, University of Athens, Greece
- P190 Controlled release of drugs from innovative multi-layered biodegradable coating on polymeric orthopaedic implants**
Nerea Argarate, Beatriz Olalde, Garbiñe Atorrasagasti, Jesus Valero, Sandra Carolina Cifuentes, Rosario Benavente, Marcela Lieblich, Jose Luis González-Carrasco
 Networking Research Centre on Bioengineering, Biomaterials and Nanomedicine, Spain
- P191 Study on calcium silicate / zein scaffold implanted in vivo by synchrotron radiation-based X-ray Imaging**
Han Guo, Jie Wei, Changsheng Liu, Tiqiao Xiao
 Shanghai Institute of Applied Physics, CAS, P R China
- P192 Fabrication and Characterization of Gelatin-based Polyurethane Vascular Graft for Tissue-engineering Applications**
Paola Losi, Enrica Briganti, Luisa Mancuso, Alice Gualerzi, Tamer Al Kayal, Simona Celi, Silvia Volpi, Giacomo Cao, Giorgio Soldani
 Laboratory of Biomaterials & Graft Technology, Institute of Clinical Physiology, Massa, Italy
- P193 Controlling the Delivery of Vascular Endothelial Growth Factor and Platelet Derived Growth Factor**
Laura Kelly, Laura Platt, Sheila MacNeil, Paul Genever, Tim Chico, Stephen Rimmer
 Department of Chemistry, University of Sheffield, UK
- P194 Cell Behaviour on Self-assembled Nanohole Arrays on Type 316L Stainless Steel Formed by Anodic Process**
Sayaka Miyabe, Yushi Fujinaga, Hiroaki Tsuchiya and Shinji Fujimoto
 Division of Materials and Manufacturing Science, Osaka University, Japan
- P195 Strontium-substituted CaP bone cements for the treatment of osteoporotic bone defects**
Matthias Schumacher, Arne Helth, Anja Lode, Anne Bernhardt, Anja Henß, Marcus Rohnke, Seemun Ray, Ulrich Thormann, Volker Alt and Michael Gelinsky
 Centre for Translational Bone, Joint and Soft Tissue Research, Technische Universität Dresden, Germany
- P196 Mesoporous bioactive glass/CaP bone cement composites as drug delivery system**
Matthias Schumacher and Michael Gelinsky
 Centre for Translational Bone, Joint and Soft Tissue Research, Technische Universität Dresden, Germany
- P197 The influence of PEG/PCL ratio on properties of PU/ β -TCP composites for orthopaedic applications**
Piotr Szczepańczyk, Kinga Pielichowska, Jan Chłopek
 AGH University of Science and Technology, Department of Biomaterials, Kraków, Poland
- P198 Effect of fibre reinforcement on the crystallinity of PEEK for articular joint implants**
Marco Regis, Simonetta Fusi, Michele Pressacco, Marco Zanetti and Pierangiola Bracco
 R&D Department, Limacorporate, Italy
- P199 Effect of surface roughness on the biocompatibility of $\text{Ti}_{40}\text{Zr}_{10}\text{Cu}_{38}\text{Pd}_{12}$ bulk metallic glass**
Andreu Blanquer, Anna Hynowska, Carme Nogués, Elena Ibáñez, Maria Dolors Baró, Jordi Sort, Eva Pellicer and Lleonard Barrios
 Dept. Biologia Cellular, Fisiologia i Immunologia, Universitat Autònoma de Barcelona, Spain
- P200 Plasma assisted production of residual solvent free PLLA electrospun scaffolds**
V. Colombo, D. Fabiani, M.L. Focarete, M. Gherardi, C. Gualandi, R. Laurita, M. Zaccaria
 Department of Industrial Engineering, Università di Bologna, Italy
- P201 Fabrication of Stable Biocatalytic Networks for the Cascadable Manufacture of Fine Chemicals**
Christopher Hickling, Helen Toogood, Alberto Saiani, Nigel Scrutton and Aline Miller
 Chemical Engineering and Analytical Sciences, Manchester Institute of Biotechnology, University of Manchester, UK
- P202 Crosslinked albumin hydrogel as adhesion barrier to prevent postoperative fibrosis**
Burkhard Schlosshauer, Dominic Stadel, Elke Rist, Helmut Wurst, Jürgen Mollenhauer, Erich K. Odermatt
 NMI Natural and Medical Sciences Institute, Reutlingen, Germany
- P203 Local Inflammatory Tissue Response After Implantation of Electrospun Polylactide Fiber Meshes With and Without Plasma-Polymerized Allylamine in Rats**
Andreas Hoene, Matthias Schnabelrauch, Ralf Wyrwa, Birgit Finke, Silke Lucke, Uwe Walschus, Michael Schlosser
 Department of Surgery, University Medical Center Greifswald, Germany
- P204 Differentiation of Macrophage Involvement in Tissue Regeneration Following Implantation of Biodegradable Matrices in Rats**
Silke Lucke, Uwe Walschus, Andreas Hoene, Jens-Wolfgang Pissarek, Matthias Schnabelrauch, Michael Schlosser
 Department of Medical Biochemistry and Molecular Biology, University Medical Center Greifswald, Germany
- P205 In vitro and in vivo osteoinductive potential of polycaprolactone-based bioactive composite scaffold fabricated via additive manufacturing technology**
Patrina S. P. Poh, Dietmar W. Hutmacher, Boris M. Holzapfel, Molly M. Stevens and Maria A. Woodruff
 Institute of Health and Biomedical Innovation, Queensland University of Technology, Australia
- P206 PLA-Glass Composites For Bone Tissue Engineering**
João S. Fernandes, Ricardo A. Pires, Rui L. Reis
 3B's Research Group, University of Minho, Guimarães, Portugal
- P207 Stability of Peptide Hydrogels in Cell Culture Conditions**
I. Nawi, V. L. Workman, A. M. Smith, A. F. Miller and A. Saiani
 School of Materials & Manchester Institute of Biotechnology, The University of Manchester, UK

- P208 Guiding bone cells with surface patterned nano-calcium phosphate**
Gillian Munir, Mohan J. Edirisinghe, Lucy Di Silvio, Miriam Rafailovich and Jie Huang
 Department of Mechanical Engineering, University College London, UK
- P209 The Potential Role of Statins in the Regeneration of Osteoporotic Tissue and the Use of Star Degradable Polymers for Controlled Local Delivery**
Jason Burke, Sarah Cartmell, Nicola Tirelli
 Institute of Inflammation & Repair, University of Manchester, UK
- P210 Effective Cellular Uptake of Exosomes Using Cationic Lipids and pH-sensitive Fusogenic Peptide**
Ikuhiko Nakase
 Nanoscience and Nanotechnology Research Center, Osaka Prefecture University, Japan
- P211 Borates-loaded Biomaterials to trigger Cell Differentiation**
P. Rico, A. Rodrigo-Navarro, M. Salmerón-Sánchez
 Center for Biomaterials and Tissue Engineering, Universitat Politècnica de València, Spain
- P212 Animal Experiment on In-vivo Galvanic Corrosion of SUS316L and Ti-6Al-4V. Observation of tissue reaction at 52 weeks after implantation**
Y. Kato, A. Ito, T. Hattori, T. Akahori, N. Kimata, K. Sato
 Dept. of Materials Science and Engineering, Meijo University, Nagoya, Japan
- P213 The degradation relationship between mechanical and in vitro testing of a phosphate glass fibre composite**
R. J. Colquhoun and Prof K.E. Tanner
 Department of Biomaterials, University of Glasgow, UK
- P214 Animal Experiment on In-vivo Galvanic Corrosion of SUS316L and Ti-6Al-4V. Surface observation and EPMA element mapping analysis**
A. Ito, Y. Kato, T. Hattori, T. Akahori, N. Kimata, K. Sato
 Dept. of Materials Science and Engineering, Meijo University, Nagoya, Japan
- P215 Nanoscale Roughness Influences on Cell Proliferation**
Prabhjeet Kaur Dhillon, Ajay Kumar, Shalmoli Bhattacharyya and Subhendu Sarkar
 Department of Physics, Indian Institute of Technology Ropar, Punjab, India
- P216 Role of Fibronectin assembly in Mesenchymal Stem Cell differentiation**
P. Rico, H. Mnatsakanyan, M. Salmerón-Sánchez
 Center for Biomaterials and Tissue Engineering, Universitat Politècnica de València, Spain
- P217 Graphene oxide and 4-arm-PPO-PEO composite hydrogels for injectable biomedical applications**
Yunki Lee, Jin Woo Bae, and Ki Dong Park
 Department of Molecular Science and Technology, Ajou University, Suwon, Republic of Korea
- P218 pH-Mediated Surfactant Release in the Development of Self-Sterilising Urinary Biomaterials**
C. P. McCoy, J. L. Trotter, N. J. Irwin, L. Carson, D. S. Jones
 School of Pharmacy, Queen's University Belfast, UK
- P219 Silica Beads Grafted with Thermoresponsive Cationic Copolymer Brush Possessing Quaternary Amine Group for Effective Thermoresponsive Ion-exchange Chromatography**
Kenichi Nagase, Mike Geven, Saori Kimura, Jun Kobayashi, Akihiko Kikuchi, Yoshikatsu Akiyama, Dirk W. Grijpma, Hideko Kanazawa and Teruo Okano
 Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Japan
- P220 Thermo-Responsive Nano-Structured Surface Modulates Cell Adhesion and Detachment**
Yoshikazu Kumashiro, Morito Sakuma, Masamichi Nakayama, Nobuyuki Tanaka, Kazuo Umemura, Masayuki Yamato and Teruo Okano
 Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Japan
- P221 Reciprocating Sliding Friction of Polyvinyl Alcohol Hydrogels as Articular Cartilage Substitutes**
Takashi Hayami, Koji Morimoto, Yoshihiro Kimura, Noriyasu Hirokawa and Tadashi Shibue
 Faculty of Biology-Oriented Science and Technology, Kinki University, Japan
- P222 Comparison of Inverse-opal and Salt-leached Silk Fibroin Scaffolds for Bone Tissue Engineering**
Marianne Sommer, Jolanda Vetsch, Jessica Leemann, Ralph Müller, Sandra Hofmann and André Studart
 Department of Materials, ETH Zurich, Switzerland
- P223 Towards Biocompatible Medical Devices: Modification of Polymer and Metal Surfaces**
J. Buchholz, C. Hess, A. Kirschning, L. Möller, M. Pflaum, S. Schmeckebeier, M. Stiesch, B. Wiegmann, A. Winkel, G. Dräger
 Institute of Organic Chemistry, Gottfried Wilhelm Leibniz Universität Hannover, Germany
- P224 Evaluation of network and pore morphology of self-assembling peptides for biomimetic therapy**
Franziska Koch and Uwe Piele
 ICB/Nanotechnology, University of Applied Sciences, Muttentz, Switzerland
- P225 Morphological Gradients for Protein-Adsorption and Blood-Interaction Studies**
Rebecca P. Huber, Katharina Maniura-Weber, Nicholas D. Spencer
 Department of Materials, ETH Zurich, Switzerland
- P226 An Innovative Intraocular Lens Surface Functionalization to Control Posterior Capsular Opacification**
Yi-Shiang Huang, Virginie Bertrand, Dimitriya Bozukova, Christophe Pagnouille, Edwin De Pauw, Marie-Claire De Pauw-Gillet and Marie-Christine Durrieu
 Institut Européen de Chimie et Biologie, University of Bordeaux I, Pessac, France
- P227 Optical Projection Tomography as a Tool for Visualizing Hydrogels Microstructures**
A. M. Soto, J. Koivisto, J. E. Parraga, J. Silva-Correia, J. M. Oliveira, R. L. Reis, M. Kellomäki, J. Hyttinen, E. Figueiras
 Computational Biophysics and Imaging Group, Tampere University of Technology, Finland

- P228 Adsorption Profiles of Inflammatory Cytokines by Activated Carbon Beads and Monoliths for Haemoperfusion**
Alma Akhmetova, Sergey Mikhailovsky, Timur Saliev, Talgat Nurgozhin
Department of Translational Medicine, Nazarbayev University, Kazakhstan
- P229 Evaluation of short-term degradation of bicomponent electrospun fibres via AFM analysis**
Marica Marrese, Vincenzo Guarino, Valentina Cirillo, Luigi Ambrosio
Institute for Polymers, Composites and Biomaterials, National Research Council of Italy, Naples, Italy
- P230 Optimization of titanium foam scaffold with bioactive surface obtained by chemical treatment**
Cristina Caparrós, Mónica Ortiz-Hernandez, Meritxell Molmeneu, Miquel Punset, Jose Antonio Calero, F. Javier Gil
Biomaterials, Biomechanics and Tissue Engineering Group, Technical University of Catalonia, Barcelona, Spain
- P231 Application of Central Composite Design to Evaluate the Effect of Dry-Spinning Parameters on Poly (ϵ -caprolactone) Fibers Properties**
B. Azimi, P. Nourpanah, M. Rabiee, M. G. Cascone, A. Baldassare, S. Arbab, L. Lazzeri
Department of Textile Engineering, Amirkabir University of Technology, Tehran, Iran
- P232 Gentamicin-Loaded Microparticles Immobilized on Porous Scaffolds for Prevention of Biomaterials-Related Bone Infections**
Urszula Posadowska, Malgorzata Krok-Borkowicz, Lucja Rumian, Elzbieta Pamula
Faculty of Materials Science and Ceramics, AGH – University of Science and Technology, Krakow, Poland
- P233 Investigating Mesenchymal Stem Cell Self-Renewal on Nanotopography**
L.C.Y. Lee, L.A. Turner, N. Gadegaard, S. Yarwood, R.M.D. Meek, M.J. Dalby
Centre for Cell Engineering, University of Glasgow, UK
- P234 Elastomeric Polycaprolactone scaffold for cardiovascular tissue engineering**
Shraddha Thakkar, Anita Mol Driessen and Frank Baaijens
Soft Tissue Biomechanics & Tissue Engineering, Eindhoven University of Technology, the Netherlands
- P235 New Injectable Elastomeric Materials for Hernia Repair and their Biocompatibility in vitro and in vivo**
J. Skrobot, L. Zair, W. Ignaczak, M. Ostrowski, M. El Fray
Division of Biomaterials and Microbiological Technologies, West Pomeranian University of Technology, Szczecin, Poland
- P236 Corrosion resistance assessment of NiTi alloys in 0.9% NaCl solution**
Camila Dias dos Reis Barros (Camila Barros) and José Antônio da Cunha Ponciano Gomes (Ponciano Gomes)
Department of Metallurgy and Materials Engineering, Federal University of Rio de Janeiro, Brazil
- P237 Supermacroporous Cryogels for Bioligand Binding**
Ganesh Ingavle, Yishan Zheng, Carol Howell, Irina Savina and Susan Sandeman
Biomaterials and Medical Devices Research Group, University of Brighton, UK
- P238 Modification of nanofiber scaffold by biologically active substances and study of biocompatibility**
Mária Hnátová, Monika Michliková, Jana Dragúňová, Dušan Bakoš
Faculty of Chemical and Food Technology, Slovak University of Technology, Bratislava, Slovakia
- P239 Pre-clinical Evaluation of Additive Manufactured Surfaces for Orthopaedic Applications**
Grace Stevenson, John Haycock, Sarrawat Rehman, James Hunt and Edward Draper
JRI Orthopaedics Ltd, Sheffield, UK
- P240 Central Venous Catheters Functionalised with Chlorhexidine-Hexametaphosphate Nanoparticles for Prolonged Anti-Biofilm Efficacy**
Helena Grady, Sarah Maddocks, Rachel Dommert, Rikke Meyer, Mira Okshevsky, Andrew Collins, Sameer Rahatekar, Michele Barbour
Bristol Centre for Functional Nanomaterials, University of Bristol, UK
- P241 Preliminary data on sol-gel silicate glasses containing magnesium and zinc for dental tissue regeneration**
G. Theodorou, E. Kontonasaki, L. Papadopoulou, N. Kantiranis, G. Zachariades, O.M. Goudouri, A. R. Boccaccini, K.M. Paraskevopoulos, P. Koidis
Department of Physics, Aristotle University of Thessaloniki, Greece
- P242 Material-driven fibronectin networks: modulating the degree of fibrillogenesis**
Hayk Mnatsakanyan, Aarón Maturana Candelas, Alexandre Rodrigo-Navarro, Patricia Rico, José Antonio Gómez Tejedor, Manuel Salmerón-Sánchez, Roser Sabater i Serra
Center for Biomaterials and Tissue Engineering, Universitat Politècnica de València, Spain
- P243 WITHDRAWN**
- P244 Development of Biodegradable Virus and miRNA Eluting Stent Technology**
Hannah Stepto, Keith Oldroyd, Lee Cronin, Andrew H Baker
College of Medical Veterinary and Life Sciences, University of Glasgow, UK
- P245 Composite bone cement to improve the primary stability of orthodontic mini-screws**
Alberto Lagazzo, Fabrizio Barberis, Elisabetta Finocchio, Cristian Restano, Marco Capurro
Department of Civil, Chemical and Environmental Engineering, University of Genoa, Italy
- P246 Characteristics and Cytocompatibility of Novel Borophosphate Glasses**
Chenkai Zhu, Ifty Ahmed, Xiaoling Liu, Andy Parsons, Jingsong Liu, Chris Rudd
Division of Materials, Mechanics and Structures, University of Nottingham, UK
- P247 Gelatin/Chitosan Microspheres for a Modulated Drug Delivery System**
Costantino Del Gaudio, Valentina Crognale, Pierluca Galloni, Domenico Ribatti, Alessandra Bianco
Department of Enterprise Engineering, University of Rome "Tor Vergata", Italy
- P248 Design of Multi-Component Artificial Extracellular Matrices and their Effects on Cells Relevant to Wound Healing**
S. Rother, S. Thönes, J. Salbach-Hirsch, S. Moeller, M. Schnabelrauch, U. Anderegg, L. C. Hofbauer, V. Hintze, D. Scharnweber
Max Bergmann Center of Biomaterials, TU Dresden, Germany

- P249 Nanowires on Ti-6Al-4V for Creation of Antimicrobial Orthopaedic Implant Surfaces**
Terje Sjöström, Angela Nobbs and Bo Su
 School of Oral & Dental Sciences, University of Bristol, UK
- P250 Evaluation of In Vitro Cytocompatibility of Alginate-Gelatin Crosslinked Hydrogels**
Bapi Sarker, Raminder Singh, Judith A. Roether, Rainer Detsch, Iwona Cicha and Aldo R. Boccaccini
 Institute of Biomaterials, University of Erlangen-Nuremberg, Germany
- P251 Osteoblastic Differentiation Induced by Bioactive Glass-Ceramic Surfaces**
E.P. Ferraz, P.T. de Oliveira, M.M. Beloti, M.C. Crovace, O. Peitl-Filho, A.L. Rosa
 School of Dentistry of Ribeirão Preto, University of São Paulo, Brazil
- P252 Effect of surfaces properties on bone differentiation in composite scaffolds**
Vincenzo Guarino, Marica Marrese, Francesca Veronesi, Paola Torricelli, Monica Sandri, Anna Tampieri, Milena Fini, Luigi Ambrosio
 Institute of Polymers, Composites and Biomaterials, National Research Council of Italy, Naples
- P253 Controlling Mechanical Properties of Electrospun Gelatin Scaffolds**
Kaido Siimon, Paula Reemann, Uno Mäeorg, Martin Järvekülg
 Institute of Physics, University of Tartu, Estonia
- P254 Nanoscale Imaging and Quantitative Nanomechanical Characterization of Biomaterials by Atomic Force Microscopy**
Rob Field, Alex Winkel, Elmar Hartmann, Torsten Mueller, Florian Kumpfe, Joerg Barner
 JPK Instruments Ltd, Cambridge, UK
- P255 Transfer of CVD Graphene onto Polymer Substrates: Implications to Blood-Contacting Surfaces**
Gordon Xiong, Antonio Castro Neto, Cleo Choong
 School of Materials Science and Engineering, Nanyang Technological University, Singapore
- P256 Contribution of new analgesic or antibacterial properties on an implant for parietal refection: an in vitro and in vivo evaluation**
Nicolas Blanchemain, Guillaume Vermet, Stephanie Degoutin, Feng Chai, Christel Rousseaux, Christel Neut, Bernard Martel, Frederic Hildebrand
 INSERM U1008, Biomaterial Research group, University Lille 2, France
- P257 Novel nano-particular calcium phosphate and carbonate phases made by electro-migration technique. A component of silica/collagen based bone replacement materials**
Benjamin Kruppke, Christiane Heinemann, Sascha Heinemann, Anne Keroué, Maria Jäger and Thomas Hanke
 Max-Bergmann-Centre of Biomaterials, Technische Universität Dresden, Germany
- P258 In-situ Synthesized Silver Nanoparticles in Silk Fibroin Nanofibers: Effect of Fibroin Morphology on Ag⁺ Release Kinetics**
Semih Calamak, Eda Ayse Aksoy, Nusret Ertas, Ceren Erdogan, Meral Ozalp, Kezban Ulubayram
 Graduate Department of Nanotechnology and Nanomedicine, Hacettepe University, Ankara, Turkey
- P259 Sustained Release of Azithromycin from an Electrospun Polycaprolactone Membrane for Guided Tissue Regeneration**
Asha Mathew, Cedryck Vaquette, Dietmar Hutmacher and Saso Ivanovski
 Tissue Engineering and Regenerative Medicine, Griffith University, Australia
- P260 Functional Characterisation of SDF-1 α GAG Binding Variants**
Nydia Panitz, Lars Baumann, Stephan Theisgen, Daniel Huster and Annette G. Beck-Sickinger
 Institute of Biochemistry, University Leipzig, Germany
- P261 Polystyrene Sodium Sulfonate Grafted Electrospun Membrane for Applications in Guided Bone Regeneration**
C. Vaquette, V. Migonney, S. Ivanovski, D. Hutmacher
 Institute of Health and Biomedical Innovation, Queensland University of Technology, Australia
- P262 Chlorhexidine-based Antimicrobial Nanoparticles as a Coating for Dental Implants**
Natalie Wood, Howard Jenkinson, Dominic O'Sullivan, Sean Davis and Michele Barbour
 Bristol Centre for Functional Nanomaterials, University of Bristol, UK
- P263 PEGylation as a method of modification of collagen-elastin based scaffolds for tissue engineering**
Joanna Skopinska-Wisniewska, Anna Bajek, Justyna Sitkowska, Alina Sionkowska
 Faculty of Chemistry, Nicolaus Copernicus University, Torun, Poland
- P264 Gelatin Biofunctionalization of Poly(L-Lactide-co-Glycolide) Surfaces by Post-Plasma Grafting of AEMA**
Malgorzata Krok-Borkowicz, Olga Musial, Paulina Kruczala, Timothy Douglas, Sandra Van Vlierberghe, Peter Dubruel, Elzbieta Pamula
 Department of Biomaterials, AGH University of Science and Technology, Krakow, Poland
- P265 Osteoinductive effects of simvastatin loading on mesoporous silica and titania nanoscaled thin films**
Miriam López-Álvarez, Vanesa López-Puente, Jorge Pérez-Juste, Julia Serra, Isabel Pastoriza-Santos, Pío González
 New Materials Group, University of Vigo, Spain
- P266 Chitosan-catechol/graphene nanocomposite for biosensing applications**
Peter Sobolewski, Magdalena Pilarz, Malgorzata Aleksandrak, Ewa Mijowska, Jacek Podolski, Mirosława El Fray
 Division of Biomaterials and Microbiological Technologies, West Pomeranian University of Technology, Szczecin, Poland
- P267 Fabrication of microparticles and patterned substrates for directing stem cell growth**
Y. Yang, L. Glennon-Alty, A. Ahmed, L. Qian, P. Murray, D. Bradshaw and H. Zhang
 Department of Chemistry, University of Liverpool, UK
- P268 Selenium-doped calcium phosphate coatings on titanium implants with inhibition properties on cancerous osteoblasts**
Cosme Rodríguez-Valencia, Miriam López-Álvarez, Julia Serra, Pío González
 Department of Applied Physics, University of Vigo, Spain

- P269 Effects of stirring condition and fluid perfusion on the in-vitro degradation of calcium phosphate cement**
Jie An, J.G.C.Wolke, S.C.G.Leeuwenburgh, J.A.Jansen
 Department of Biomaterials, Radboud University Medical Center, The Netherlands
- P270 Ultrastructural features of mesenchymal stem cells in calcium alginate hydrogel during osteogenic differentiation by means of FIB-SEM**
Jakub Grzesiak, Krzysztof Marycz, Agnieszka Śmieszek, Anna Siudzińska
 Electron Microscopy Laboratory, Wrocław University of Environmental and Life Sciences, Poland
- P271 High Throughput Production and Analysis of Tissue Engineering Scaffolds prepared using Combinatorial Chemistry**
Erwin Zant, Maarten M. Blokzijl, Dirk W. Grijpma
 Department of Biomaterials Science and Technology, University of Twente, The Netherlands
- P272 Relationship between physical properties and biological response in tyrosine-derived polyarylates explored by association rules**
Daniela C. Soto and Loreto M. Valenzuela
 Department of Chemical and Bioprocess Engineering, Pontificia Universidad Católica de Chile
- P273 Generation of functional oxygen groups on parylene C for enhanced biocompatibility: LDI-MS investigations**
M. Golde-Cepa, N. Aminlashgari, M. Hakkarainen, K. Envall, A. Kotarba
 Faculty of Chemistry, Jagiellonian University, Krakow, Poland
- P274 Controlled Drug Delivery From Bioresorbable Magnesium Orthopaedic Implants**
Jessica A. Lyndon, Ben J. Boyd and Nick Birbilis
 Department of Materials Engineering, Monash University, Australia
- P275 Effect of Different Crosslinking Treatments on the Physical Properties of Collagen-based Scaffolds**
Luca Salvatore, *Deborah Pedone*, Emanuela Calò, Valentina Bonfrate, Marta Madaghiele
 Department of Engineering for Innovation, University of Salento, Italy
- P276 Degradation and mechanical properties of biodegradable PLGA film**
Reyhaneh Neghabat Shirazi, Yury Rochev, Peter McHugh
 Mechanical and Biomedical Engineering, National University of Ireland, Galway
- P277 Temporal Analysis of Dissolution By-Products and Genotoxic Potential of Spherical Zn-Si Bioglass: "Imageable beads" for Transarterial Embolization**
Muhammad Sami Hasan, Sharon Kehoe and Daniel Boyd
 Department of Applied Oral Sciences, Dalhousie University, Halifax, Canada
- P278 A modular flow-chamber bioreactor as a tool for the analysis of degradable materials**
Frank Feyerabend, Ralf Pörtner and Regine Willumeit
 Institute of Materials Research, Helmholtz-Zentrum Geesthacht, Germany
- P279 Use of a PTMC-PEG-PTMC coated PTMC film as a postoperative adhesion barrier**
Vincent Verdoold, Ruben R.M. Vogels, Kevin W.Y. van Barneveld, Nicole D. Bouvy and Dirk W. Grijpma
 MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, The Netherlands
- P280 Comparison of Sr-substituted Hydroxyapatite Obtained of Various Precursors through Neutralization Reaction: Characterisation at the Bulk and Particle Level**
L. Stipnice, K. Salma-Ancane and L. Berzina-Cimdina
 Institute of General Chemical Engineering, Riga Technical University, Latvia
- P281 Hybrid Multi-layered Coatings for Surface Functionalization of Magnesium alloys for biomedical applications**
Laura Córdoba, Christophe Hély, Thibaud Coradin, Fátima Montemor
 Instituto Superior Técnico, Technical University of Lisbon, Portugal
- P282 Degradation in the Jar: Optimising the *in vitro* enzymatic degradation of collagen-based devices**
Ayélén L. Helling, Eleni Tsekoura, Gerard Wall, Yves Bayon, Abhay Pandit, Dimitrios Zeugolis
 Network of Excellence for Functional Biomaterials, National University of Ireland, Galway
- P283 Composite Collagen/Bioceramics Strips, Plugs for Bone Filling Defect Repair: A Comparative Study**
Thomas Miramond, Thibaut Galtier, Guy Daculsi, Pascal Borget
 Inserm UMRS 791, Université de Nantes, France
- P284 Development of Artificial Stem Cell Microenvironments for Tissue Engineering Applications**
Ilida Ortega Asencio, Sheila MacNeil, Aileen Crawford, Paul Hatton, Frederik Claeysens
 School of Clinical Dentistry, University of Sheffield, UK
- P285 Fabrication of dispersible nanocrystals of bioceramics via a modified Pechini method under non-stoichiometric condition**
Yuko Omori, Masahiro Okada, Shoji Takeda, Naoyuki Matsumoto
 Graduate School of Dentistry, Osaka Dental University, Japan
- P286 Titanium with Nanotopography Drives Mesenchymal Stem Cells to Osteoblast Differentiation through miR-4448, -4708 and -4773 Downregulation**
R.B. Kato, B. Roy, F.S. de Oliveira, E.P. Ferraz, P.T. de Oliveira¹, M.Q. Hassan, A.L. Rosa, *M.M. Beloti*
 School of Dentistry of Ribeirão Preto, University of São Paulo, Brazil
- P287 Semi-interpenetrating polymer networks (SIPNs) incorporating polygalacturonic acid as biocompatible materials for implantable medical devices**
A. O' Carroll, C. McCoy and *L. Carson*
 School of Pharmacy, Queen's University Belfast, UK

- P288 In Vivo Assessment of Titanium Devices loaded with gentamicin in a methicillin-resistant *Staphylococcus aureus* Rabbit Osteomyelitis Experimental Model**
Gilles Amador, Loic Pichavant, Hélène Carrié, Laurent Plawinski, Valérie Héroguez, Cédric Jacqueline and Marie-Christine Durrieu
 Faculté de Médecine, Université de Nantes, France
- P289 Radially Aligned Collagen Scaffolds for Deterministic 3D Models of Cancer Migration**
Anke Husmann, Jonathan Campbell, Samuel Troughton, Robert Hume, Christine J. Watson and Ruth Cameron
 Department of Materials Science and Metallurgy, University of Cambridge, UK
- P290 Recombinant Production of Antimicrobial Spider Silk for Wound Dressing Materials**
L. Nilebäck, R. Jansson and M. Hedhammar
 Department of Anatomy, Physiology and Biochemistry, Swedish University of Agricultural Sciences, Sweden
- P291 Sol-Gel Hybrids with RAFT-Polymerised Branched Methacrylate Copolymers as Organic component for Tissue Engineering**
Justin Chung, Anthony Maçon, Theoni Georgiou, Julian R. Jones
 Department of Materials, Imperial College London, UK
- P292 In vitro Evaluation of a Novel Injectable Thermo-Responsive Polymeric Hydrogel for the Delivery of Self-Assembly Peptide Nanoparticles Containing an Osteoconductive Agent**
S. Pentlavalli, P. Chambers, A. Massey, M. O'Doherty, H. McCarthy and N. Dunne
 School of Mechanical and Aerospace Engineering, Queen's University Belfast, UK
- P293 Design of Drug-immobilized Polylactide-graft-Poly(ethylene glycol) as a Temperature-Responsive Injectable Polymer for Controlled Release of Low-molecular-weight Water Soluble Drugs**
Yuichi Ohya, Masay Umezaki, Yasuyuki Yoshida, Akihiro Takahashi and Akinori Kuzuya
 Department of Chemistry and Materials Engineering, Kansai University, Japan
- P294 Localized Corrosion Behaviour of Stainless Steel and Titanium Based Hard Tissue Implants**
Ilven Mutlu and Enver Oktay
 Metallurgical and Materials Engineering Department, Istanbul University, Turkey
- P295 Degradation of Calcium-Phosphate Based Glasses Controlled by TiO₂ Addition**
A. M. B. Silva, J. M. Oliveira, M. H. V. Fernandes
 Centre for Research in Ceramics and Composite Materials, University of Aveiro, Portugal
- P296 Comparison of UV and EDC Cross-linking on Mechanical Properties of Collagen-based Scaffolds for Myocardial Tissue Engineering**
Natalia Davidenko, Carlos Schuster, Ruth Cameron, Serena Best
 Department of Materials Science and Metallurgy, University of Cambridge, UK
- P297 Electrochemical Corrosion Behaviour of Highly Porous Beta-Type Ti-Nb-Cu Alloy**
Ilven Mutlu
 Metallurgical and Materials Engineering Department, Istanbul University, Turkey
- P298 Recombinant Affinity Silk for Presentation of Active Protein Domains**
R. Jansson, N. Thatikonda, P.-Å. Nygren, M. Hedhammar
 Department of Anatomy, Physiology and Biochemistry, SLU, Sweden
- P299 One-pot synthesis of hybrid biocompatible hydrogels based on methacrylamide gelatin and polyacrylamide**
A. Serafim, C. Tucureanu, D. Petre, D.M. Dragusin, A. Salageanu, S. Van Vlierberghe, P. Dubruel, I.C. Stancu
 University Politehnica of Bucharest, Romania
- P300 Bactericidal and cell compatible titanium surfaces with TiO₂ nanowires**
T. Diu, M. Ryadnov, N. Faruqi, B. Lamarre, H. Jenkinson and B. Su
 School of Oral and Dental Sciences, University of Bristol, UK
- P301 Precise Hyaluronan-tyramine synthesis for tailored cellular microenvironments**
Claudia Loebel, Matteo D'Este, Mauro Alini, Marcy Zenobi-Wong and David Eglin
 AO Research Institute Davos, Switzerland
- P302 Hyaluronic Acid-Coated Chitosan Nanoparticles: the Influence of Hyaluronic Acid Presentation**
Arianna Gennari, Erwin Hohn, Abdulaziz Almalik, Nicola Tirelli
 Institute of Inflammation and Repair, University of Manchester, UK
- P303 Real-time Monitoring of DNA Plasmid Interactions with Poly (ε-lysine) Dendrons using Optical Waveguide Lightmode Spectroscopy (OWLS)**
Steve Meikle, Valeria Perugini, Mariagemiliana Dessi, Wanda Lattanzi, Enrico Pola, Giandomenico Logroscino, Gary Phillips, Matteo Santin
 School of Pharmacy and Biomolecular Sciences, University of Brighton, UK
- P304 The Atomic-Scale Structure of Bio-Resorbable Glasses: Na₂O:P₂O₅**
David Pickup, Robert Moss, Jenni Vibert and Robert Newport
 School of Physical Sciences, University of Kent, UK
- P305 Preparation and characterization of Sr, Zn, Si and Fe-doped hydroxyapatite nanoparticles**
Zhitong Zhao, Montserrat Espanol, Maria-Pau Ginebra
 Department Materials Science and Metallurgy, Technical University of Catalonia, Spain
- P306 Endothelization and thrombogenicity response of CoCr alloy nano depth patterns for cardiovascular stents**
R. Schieber, M. Fernández-Yagüe, M. Hans, M. Díaz-Ricart, G. Escolar, F. Javier Gil, F. Mücklich, M. Pegueroles
 Materials Science Department, Universitat Politècnica de Catalunya, Spain
- P307 Cell Spraying Approach *in vitro* for Coating of Respiratory Tissue Engineered Constructs**
A. L. Thiebes, S. Albers, S. Jockenhoevel and C. G. Cornelissen
 Helmholtz-Institute, RWTH Aachen University, Germany

- P308 Biodegradable hyper-branched tissue adhesives for meniscus tears**
Agnieszka I. Bochyńska, Tony G. van Tienen, Gerjon Hannink, Pieter Buma, Dirk W. Grijpma
 Department of Orthopaedics, Radboud University Nijmegen Medical Centre, The Netherlands
- P309 WITHDRAWN**
- P310 Impact of Surface Treatment on the Properties of Dental Implant Materials**
M. Murphy, R. Lindsay, A. Thomas and N. Silikas
 School of Materials, University of Manchester, UK
- P311 Monodisperse microspheres loaded with gentamicin dioctyl sodium sulfosuccinate for the treatment of orthopaedic infections**
Gert-Jan A. ter Boo, Dirk W. Grijpma, Geoff Richards, Fintan T. Moriarty and David Eglin
 AO Foundation, Davos, Switzerland
- P312 Retention of Myoblast Differentiation Capacity in 3D Culture on TIPS Microspheres**
Nina Parmar, Richard Day
 Applied Biomedical Engineering Group, University College London, UK
- P313 Corrosion behaviour of beta titanium alloys containing zirconium for dentistry**
J. Fojt, L. Joska, A. Bernatikova and J. Malek
 Department of Metals and Corrosion Engineering, Institute of Chemical Technology in Prague, Czech Republic
- P314 Surface modification of Ti-surfaces by alginate polyelectrolyte layers**
Dana Kubies, Ognen Pop-Georgievski, Eliška Mázl-Chánová, Josef Zemek, Neda Neykova, Roman Deminachuk, Milan Houska, Elena Filová, Lucie Bačáková, František Rypáček
 Institute of Macromolecular Chemistry, Academy of Sciences of the Czech Republic
- P315 Hydrophobic quaternized chitosan for efficient nanoparticle formation and transfection of therapeutic oligonucleotides**
Pedro M.D. Moreno, Joyce C. Santos, Carla P. Gomes, Aida Varela-Moreira, Artur Costa, Francisco Mendonça, Ana P. Pêgo
 Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- P316 In Vitro Response of Human Osteoprogenitor Cells to Cross-Linked Poly(Lactide-co-Caprolactone) Dimethacrylate for Bone Repair**
Laura Brown, Jessica Gwynne, David Shepherd, Leander Poozca, Gerhard Hildebrand, Klaus Liefeth, Roger Brooks, Serena Best
 Department of Materials Science & Metallurgy, University of Cambridge, UK
- P317 Drug delivery carriers based on two functionalized spider silk proteins: a novel approach for cancer therapy**
Anna Florcza, Katarzyna Jastrzebska, Andrzej Mackiewicz, Hanna Dams-Kozłowska
 NanoBioMedical Centre, Adam Mickiewicz University, Poznan, Poland
- P318 Controlling Intramembranous Bone Mineralisation using a Bone Tissue Engineering Approach**
Anthony J. Deegan, Halil M. Aydin, Bin Hu, Sandeep Konduru, Jan H. Kuiper, Ying Yang
 Institute of Science and Technology in Medicine, Keele University, UK
- P319 Generation of electrospun yarns for use as tissue engineered blood vessel scaffolds**
Richard O'Connor and Garrett B. McGuinness
 Centre for Medical Engineering Research, Dublin City University, Ireland
- P320 Injectable Thermo-responsive Hyaluronan Hydrogel in a Rabbit Osteochondral Defect Model**
D. Eglin, M. D'Este, I. Dresing and M. Alini
 AO Research Institute Davos, Switzerland
- P321 Modification of Porcine Pericardium with Low-Energy Non-thermal Electron Beam**
Jessy Schönfelder, Eberhard Spörl, Richard Funk, Christiane Wetzler
 Fraunhofer Institute for Electron Beam and Plasma Technology, Germany
- P322 Developing a Method for Tracking and Quantifying Metallic Particle Internalisation**
Hayley Floyd, Janet Lord, Edward Davies, Owen Addison, Hamid Dehghani, Liam Grover
 School of Chemical Engineering, University of Birmingham, UK
- P323 Endothelialization of gas exchange membranes to provide antithrombogenicity**
A. Wenz, K. Linke, M. Schandar, F. Metzger, E. Novosel, J. Schneider, P. Kluger
 Institute of Interfacial Process Engineering and Plasma Technology, University of Stuttgart, Germany
- P324 Influence of TCP Content on Chitosan Agglomerated Scaffold Properties**
Martyna Kucharska, Katarzyna Walenko, Małgorzata Lewandowska-Szumieł, Tomasz Brynk, Tomasz Ciach
 Biomedical Engineering Laboratory, Warsaw University of Technology, Poland
- P325 In-situ Charge Formation on Hydroxylapatite Coatings**
L. Pluduma, K. A. Gross, H. Koivuluoto, P. Vuoristo, M. Kylmälahti, A. Bystrova, Yu. Dekhtyar
 Institute of Biomaterials and Biomechanics, Riga Technical University, Latvia
- P326 Preparation and Characterization of Porous Hydroxyapatite Based Microcarriers for Cell and Drug Delivery**
Merve Guldiken, Sibel Ataoğlu, Caner Durucan, Can Özen, Dilek Keskin and Ayşen Tezcaner
 Department of Biotechnology, Middle East Technical University, Ankara, Turkey
- P327 In Vitro studies to measure the inflammatory response of crosslinked poly(lactide-co-caprolactone) dimethacrylate scaffolds**
David Shepherd, Laura Brown, Leander Poozca, Gerhard Hildebrand, Klaus Liefeth, Roger Brooks, Serena Best
 Department of Materials Science and Metallurgy, University of Cambridge, UK
- P328 A comparison of two approaches to the formation of antibacterial surfaces: doping with bactericidal element vs drug loading**
I.V. Batenina, D.V. Shtansky, Ph.V. Kiryukhantsev-Korneev, A.N. Sheveyko, N.Yu. Anisimova and N.A. Gloushankova
 National University of Science and Technology "MISIS", Russia

- P329 Investigation of Factors Influencing Deposition of Nanocomposite Coating onto Open Cell Foams using Layer-by-Layer Assembly: Design of Experiment Approach**
Monika Ziminska, Helen McCarthy, Nicholas Dunne and Andrew Hamilton
School of Mechanical & Aerospace Engineering, Queen's University Belfast, UK
- P330 In-vivo response of a novel Ti-Ta-Zr-Nb alloy for medical implants**
Patrik Stenlund, Omar Omar, Ulrika Brohede, Susanne Norgren, Lena Emanuelsson, Jukka Lausmaa, Peter Thomsen and Anders Palmquist
BIOMATCELL VINN Excellence Center of Biomaterials and Cell Therapy, Sweden
- P331 Adipose derived stem cells cultured in 2D and 3D settings for the use in bone tissue engineering**
Claudia Kleinbans, Inga Satller, Lena Schmohl, Jakob Barz, Thomas Schiestel, Günter Tovar, Petra J. Kluger
Institute for Interfacial Process Engineering and Plasma Technology, University of Stuttgart, Germany
- P332 Bioengineered spider silk spheres as anti-cancer drug carriers**
Katarzyna Jastrzebska, Anna Florczak, Yinnan Lin, Rosalyn Abbott, Andrzej Mackiewicz, David L. Kaplan, Hanna Dams-Kozłowska
NanoBioMedical Centre, Adam Mickiewicz University, Poznan, Poland
- P333 Aligned electrospun PLGA fibres reinforcing tubular small intestine submucosa**
Omaer Syed, Richard Day, Jonathan Knowles
Eastman Dental Institute, University College London, UK
- P334 Hyaluronic Acid Regulation of Cytokine Secretion, GAG Production and Permeability in Urothelial Cells**
Peadar Rooney, Akshay Srivastava, Leo Quinlain, Abhay Pandit
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway
- P335 Nanohelical Shape and Periodicity dictate Stem Cell Fate**
R. K. Das, O. F. Zouani, G. Kemper, L. Plawinski, C. Labrugère, R. Oda and M-C. Durrieu
Institute of Chemistry & Biology of Membranes & Nanoobjects, Université Bordeaux, Pessac, France
- P336 Controlling the Modulus of Gellan Gum Hydrogels for Inkjet Printing Cell Culture Substrates**
Sam Moxon & Alan M Smith
Department of Pharmacy, University of Huddersfield, UK
- P337 Nano-Micro Architectural Hybrid Composite Scaffold for Bone Tissue Engineering**
Prabhash Dadhich, Bodhisatwa Das, Pavan Kr. Srivas, Pallabi Pal, Sabyasachi Ray, Santanu Dhara
School of Medical Science and Technology, Indian Institute of Technology Kharagpur, India
- P338 Bioactive and Highly Porous Nanofibres via Solution Blow Spinning**
Jonny J. Blaker, Eudes Leonnan, Ana Letícia Braz, Isaque Jerônimo, Aldo R. Boccaccini, Juliano E. Oliveira, Eliton S. Medeiros, Showan N. Nazhat
Materials Science Centre, Manchester University, UK
- P339 The Reciprocal Relationship between Pore Size and Crosslinking, and Their Impact on Porous Scaffold Strength**
S. Ali Poursamar, Alexander N. Lehner, A.P.M. Antunes
Institute for Creative Leather Technology, University of Northampton, UK
- P340 Tuning the 3D Architecture of Gelatin Hydrogel-PLLA Combination Scaffolds**
Jasper Van Hoorick, Marica Markovic, Aleksandr Ovsianikov, Tristan Fowler, Oskar Hoffmann, Peter Dubrue and Sandra Van Vlierberghe
Polymer Chemistry & Biomaterials Research Group, Ghent University, Belgium
- P341 Fine-Tuning Self-Assembling Peptide Hydrogels for Cell Culture Applications**
Laura Szkolar, Alberto Saiani, Aline F Miller, Julie E Gough
School of Materials, University of Manchester, UK
- P342 Sol-Gel Dip-Coating for Immobilization of Poly (ϵ -lysine) Dendrons on Biomaterials Surfaces for Regenerative Medicine Applications**
Maria Elena Verdenelli, Steve Meikle, Matteo Santin, Roberto Chiesa
Department of Chemistry, Materials and Chemical Engineering, Politecnico di Milano, Italy
- P343 Characterization of Silicone-polycarbonate-urethane/PDMS based Material for Polymeric Heart Valves**
Marianna Asaro, Tamer Al Kayal, Silvia Volpi, Paola Losi, Simona Celi, Mattia Glauber, Giorgio Soldani
National Council of Research, Institute of Clinical Physiology, Massa, Italy
- P344 Study of the effect of SLS manufacturing parameters on the porosity of PHB scaffolds for tissue engineering**
Tatiana F. Pereira, Bruna N. Teixeira, Sara C Marques, Marcelo F. Oliveira, Izaque A. Maia, Jorge V. L. Silva, Gutemberg G. Alves, Marysilvia F. Costa, Rossana M. S. M. Thiré
Programa de Engenharia Metalúrgica e de Materiais, Federal University of Rio de Janeiro
- P345 Assessment of the Corrosion Behaviour and Cytocompatibility of a Nano-fluorided Coating Obtained by Simple Chemical Conversion on AZ31 Biodegradable Mg Alloy**
Emerson Alves Martins, Dorota Artymowicz, Kwangchul Shin, Andrey I. Shukalyuk, Roger C. Newman
Department of Chemical Engineering and Applied Chemistry, University of Toronto, Canada
- P346 Mechanical Response of Calcium Phosphate Bioceramics**
D.E. Mouzakis, S.P. Zaoutsos, S. Rokidi, N. Bouropoulos
Department of Mechanical Engineering, Technological Educational Institute of Thessaly, Larissa, Greece
- P347 Bacterial Cellulose Based Electrospun Scaffolds for Bone Tissue Engineering**
Deniz Atila, Ayten Karataş, Dilek Keskin, Ayşen Tezcaner
Department of Engineering Sciences, Middle East Technical University, Ankara, Turkey
- P348 WITHDRAWN**
- P349 The Influence of Porosity and Pore Shape of PCL Electro-spun Nano-fibrous Meshes on Macrophage Activation**
Kieran P. Fuller, Colm O'Dowd, Abhay Pandit, and Dimitrios Zeugolis
Network of Excellence for Functional Biomaterials, National University of Ireland, Galway

- P350 Production and Characterization of a Chitosan Coating on Titanium with Silver Nanoparticles**
Daniel Rodríguez, María Godoy-Gallardo, Marc Avilès, Montserrat Español, F. Javier Gil
 Biomaterials, Biomechanics and Tissue Engineering group, Technical University of Catalonia, Barcelona, Spain
- P351 Photo-crosslinkable and biopolymer-based inks for inkjet-bioprinting of artificial cartilage**
Eva Hoch, Achim Weber, Günter E.M. Tovar and Kirsten Borchers
 Institute for Interfacial Process Engineering, University of Stuttgart, Germany
- P352 A Bioreactor-based 3D Culture System for skeletal Muscle Engineering in Fibrin Scaffolds**
Philipp Heher, Christiane Fuchs, Johanna Prüller, Babette Maleiner, Josef Kollmitzer, Dominik Rünzler, Andreas Teuschl, Susanne Wolbank and Heinz Redl
 Trauma Care Consult, Vienna, Austria
- P353 WITHDRAWN**
- P354 Functionalization of Polyurethane Substrates with Dendrons for Stem Cell Culture**
Nicola Contessi, Serena Bertoldi, Steven Meikle, Anna Guildford, Silvia Farè, Matteo Santin and Maria Cristina Tanzi
 Department of Chemistry, Materials and Chemical Engineering "G. Natta", Politecnico di Milano, Italy
- P355 Quantification of Volume and Size Distribution of Internalised Calcium Phosphate Particles and Their Influence on Cell Fate**
Richard Williams, Midhat Salimi, Gary Leeke, Paula Mendes, Liam Grover
 School of Chemical Engineering, University of Birmingham, UK
- P356 Functional PEPM-A-HA cryogels for drug conjugation and cartilage integration**
Joana Magalhaes, Luis Rojo del Olmo, Lara M. Nieto Couce, Julio San Roman and Francisco J. Blanco
 CIBER in Bioengineering, Biomaterials and Nanomedicine, Spain
- P357 Biaxial stretching of poly(L-lactide) tubes for improvement of mechanical properties**
A. Løvda, J. Wenzel Andreasen, L. Pilgaard Mikkelsen, K. Agersted, K. Almdal
 Department of Micro- and Nanotechnology, Technical University of Denmark
- P358 Controlled IL-2 Delivery from Novel Photocured Biodegradable Poly (decane-co-tricarballoylate) Elastomers**
Husam M. Younes and Mohammad Shaker
 Pharmaceuticals and Polymeric Drug Delivery Research laboratory, Qatar University, Doha
- P359 Incorporation of Elastin Enhancement Agents on Nano-scale Fibers**
F. Damanik, C. van Blitterswijk, J. Rotmans and L. Moroni
 Department of Tissue Regeneration, University of Twente, The Netherlands
- P360 Mineralized Porous Pullulan Microcarriers for Bone Tissue Engineering**
Hazal Aydoğdu, Dilek Keskin, Ayşen Tezcaner, Erkan Türker Baran
 Biomedical Engineering, Middle East Technical University, Turkey
- P361 Interaction Study between Functionalised Si-Nanoparticles and Colon Carcinoma Cells for Theranostic Applications**
Helena Montón, Colin Moore, Antonio Aranda-Ramos, Vladimir Gubala, Arben Merkoçi, Carme Nogués
 Department Biologia Cellular, Fisiologia i Immunologia, Universitat Autònoma de Barcelona, Spain
- P362 Expression of Bone Markers in Pre-Osteoblastic Cells Grown on Titanium Surface with Nanotopography**
L. M. S. de Castro-Raucci, L. N. Teixeira, P.T. de Oliveira, A. L. Rosa, M.M. Beloti
 School of Dentistry of Ribeirão Preto, University of São Paulo, Brazil
- P363 A novel method to measure the primary stability of dental implants and orthodontic screws**
Fabrizio Barberis, Alberto Lagazzo, Stefano Benedicenti, Marco Migliorati, Marco Capurro
 Department of Civil, Chemical and Environmental Engineering, University of Genoa, Italy
- P364 Development of novel tamponades to treat retinal detachments**
Victoria Kearns, Robert Poole, Albert Caramoy and Rachel Williams
 Department of Eye and Vision Science, University of Liverpool, UK
- P365 Ambient Temperature Patterning of Bioactive Deposits on Curved Metallic Substrates For Orthopaedic Implants**
A. Nithyanandan and M. Edirisinghe
 Mechanical Engineering, University College London, UK
- P366 Effect of Substrate Geometry on Mineralization and Cell Proliferation of Calcium Phosphate Ceramics**
E.R. Urquía Edreira, Astghik Hayrapetyan, J.G.C. Wolke, J.A. Jansen, J.J.J.P. van den Beucken
 Department of Biomaterials, Radboud University Nijmegen Medical Center, The Netherlands
- P367 Bone mineralization in Zebrafish embryos treated with Silicon ions**
M. Montazerolghaem, L. Nyström, H. Engqvist and M. Karlsson Ott
 Department of Engineering Sciences, Uppsala University, Sweden
- P368 PolyHIPE-based porous microparticles for bone tissue engineering**
T. Paterson, C. Sherborne, R. Owen, S. Puwun, G. Reilly, F. Claeysens
 Department of Materials Science and Engineering, University of Sheffield, UK
- P369 Retrieval Analysis of Titanium – Nitride Coated Femoral Heads Articulating Against Polyethylene**
Łukasz Łapaj, Justyna Wendland, Adrian Mróz, Jacek Markuszewski, Tomasz Wiśniewski
 Department of General Orthopaedics, Musculoskeletal Oncology and Trauma Surgery, Poznan University of Medical Sciences, Poland
- P370 Investigation of Ion Exchange between Silicate-substituted Bone Graft Substitutes and Cell Culture Media and the effect on Osteoblast-like Cell Response**
N. K. Chana, S. C.F. Rawlinson and K. A. Hing
 School of Engineering and Materials Science, Queen Mary University of London, UK

- P371 Highly Reinforced Bioactive Glass – Gellan Gum Composite Hydrogels For Biomedical Applications**
Ana Gantar, Rok Kocen and Saša Novak
 Department for Nanostructured materials, Jožef Stefan Institute, Slovenia
- P372 In vitro testing of osteoinductivity and osteoconductivity of titanium alloys with nanostructured surface for orthopaedic applications**
E. Jablonská, J. Lipov, J. Fojt, L. Joska, T. Ruml
 Department of Biochemistry and Microbiology, Institute of Chemical Technology, Prague, Czech Republic
- P373 Influence of collagen cross-linking on fibroblast and macrophage response**
Luis M. Delgado, Abhay Pandit, Dimitrios I. Zeugolis
 Network of Excellence for Functional Biomaterials, National University of Ireland, Galway
- P374 Preparation of chitosan nanowires and their application to hemostasis**
Ying-Chiang Ho and Yi-Chang Chung
 Institute of Biotechnology, National University of Kaohsiung, Taiwan, ROC
- P375 Mobilization of Mesenchymal Progenitor Cells to Improve Bone Healing**
P.S. Lienemann, A.S. Kivelioe, S. Metzger, S. Höhnle, A. Roch, O. Naveiras, A. Sala, V. Milleret, F. E. Weber, W. Weber, M.P. Lütolf, M. Ehrbar
 Department of Obstetrics University Hospital, Zürich, Switzerland
- P376 Modification of polylactide surfaces with PLA-b-PEO nano-colloids**
Eliska Mazl Chanova, Ognen Pop-Georgievski, Marta Maria Kumorek, Ludka Machova and Frantisek Rypacek
 Institute of Macromolecular Chemistry of the Academy of Sciences of the Czech Republic, Prague
- P377 Local Delivery of Alendronate and Bone Remodelling in Rat Models**
Necati Harmankaya, Johan Karlsson, Anders Palmquist, Mats Halvarsson, Martin Andersson and Pentti Tengvall
 Department of Biomaterials, Sahlgrenska Academy at University of Gothenburg, Sweden
- P378 Localized cell differentiation with BMP-2 in a PEG scaffold using a streptavidin linker**
S. Metzger, P. S. Lienemann, C. Ghayor, M. Karlsson, F. E. Weber, W. Weber, M. Ehrbar
 Department of Obstetrics, University Hospital Zurich, Switzerland
- P379 Plasma Spraying of Zinc Substituted Hydroxyapatite**
David Shepherd, Roger Brooks and Serena Best
 Department of Materials Science and Metallurgy, University of Cambridge, UK
- P380 Candida glabrata in mouthwash -coated endotracheal tubes: antibiofilm activity by electronically scanning microscopy**
Danielle Bezerra Cabral, Evandro Watanabe and Denise de Andrade
 Fundamental Nursing, University of São Paulo at Ribeirão Preto, Brazil
- P381 Simple Silver Deposition Strategy for Antibacterial Titanium Implants**
Kennedy Omoniala, David Armitage, Susannah Walsh
 Leicester School of Pharmacy, De Montfort University, Leicester, UK
- P382 Assessment of the bioactivity of gold doped hydroxyapatite-polyvinyl alcohol nanocomposites**
Amany Mostafa, Hassane Oudadesse and Mayyada El Sayed
 Biomaterials Department, National Research Centre, Cairo, Egypt
- P383 Haemocompatibility of Citrate Stabilised Gold Nanoparticles**
Brian G. Cousins, Niloofar Ajdari & Alexander M. Seifalian
 Centre for Nanotechnology & Regenerative Medicine, University College London, UK
- P384 Vitronectin Tunes The Biological Activity Of Material-Driven Fibronectin Matrices**
M. Cantini, K. Gomide, C. González-García, and M. Salmerón-Sánchez
 Biomedical Engineering Research Division, University of Glasgow, UK
- P385 Investigation on Mechanical Loading of Hydrogels for Cartilage Tissue Engineering**
Stefanie Biechler, Sandy Williams and Ruochong Fei
 Bose Corporation, ElectroForce Systems Group, Eden Prairie, USA
- P386 Biological Performance of Cell-Laden Methacrylated Gellan Gum Hydrogels**
Joana Silva-Correia, Mariana B. Oliveira, João F. Mano, Joaquim M. Oliveira and Rui L. Reis
 3B's Research Group, University of Minho, Guimarães, Portugal
- P387 Melt Electrospinning Of PCL/Bioactive Glass Composites In Direct Writing For Highly Ordered Scaffolds For Non-Load Bearing Defects**
Keith A. Blackwood, Nikola Ristovski, Sam Liao, Nathalie Bock, Jionguy Ren, Giles T.S. Kirby, Roland Steck, Molly M. Stevens, Maria A. Woodruff
 Institute of Health & Biomedical Innovation, Queensland University of Technology, Brisbane, Australia
- P388 Material-driven fibronectin fibrillogenesis promotes growth factor binding and stem cell differentiation**
V. Llopis-Hernández, M. Cantini, P. Rico, M. Tsimbouri, A. García, M. Dalby, M. Salmerón-Sánchez
 Division of Biomedical Engineering, University of Glasgow, UK
- P389 Design, Development and Characterization of Novel Polyacrylates to direct Kidney Progenitor / Stem Cell Differentiation**
Isabel Hopp, Rachel Williams, Simon Dixon, Patricia Murray
 Institute of Translational Medicine, University of Liverpool, UK
- P390 Antibacterial Polyurethane Surfaces: Modification with Chitosan by Covalent Immobilization**
Filiz Kara, Eda Ayse Aksoy, Serpil Aksoy and Nesrin Hasirci
 Center of Excellence in Biomaterials and Tissue Engineering, Middle East Technical University, Turkey
- P391 Catechol-Chitosan/Genipin Hydrogel as Mucoadhesive Buccal Drug Delivery System**
J. Xu, S. Strandman, J. Zhu, J. Barralet and M. Cerruti
 Department of Mining and Materials Engineering, McGill University, Montreal, Canada

- P392 Inflammatory Response to Magnesium Based Biodegradable Implant Materials**
Maria Costantino, Bérengère Luthringer, Regine Willumeit
Helmholtz-Zentrum Geesthacht, Zentrum für Material- und Küstenforschung, Germany
- P393 Surface modification of poly(D,L-lactic acid) scaffolds for orthopedic applications: a biocompatible, non-destructive route via diazonium chemistry**
H. Mahjoubi, J. Kinsella, M. Murshed and M. Cerruti
Materials Engineering, McGill University, Montreal, Canada
- P394 Bioactive glass for treatment of tooth hypersensitivity during or after treatment with bleaching**
Nataša Drnovšek, Kaja Križman, Sebastjan Perko, Saša Novak
Department for Nanostructured Materials, Jožef Stefan Institute, Slovenia
- P395 Selenium-containing hydroxyapatites – spectroscopic studies**
J. Kolmas, E. Oledzka and M. Sobczak
Department of Inorganic and Analytical Chemistry, Medical University of Warsaw, Poland
- P396 Determination of metallic biomaterials susceptibility to crevice corrosion**
L. Joska, J. Fojt, A. Bernatíkova
Department of Metals and Corrosion Engineering, Institute of Chemical Technology in Prague, Czech Republic
- P397 Characterization of Poly (Lactic-co-Glycolic Acid) / Poly (Isoprene) Blend for Application in Tissue Engineering**
Douglas Ramos Marques, Luis Alberto dos Santos, Sarah Harriet Cartmell, Julie Elizabeth Gough
Materials Science Centre, University of Manchester, UK
- P398 Calcium phosphate nanoparticles carrying BMP-7 plasmid DNA induce osteogenic differentiation in MC3T3-E1 pre-osteoblasts**
Chrystalleni Hadjicharalambous, Viktoriya Sokolova, Diana Kozlova, Matthias Epple and Maria Chatzinikolaïdou
Department of Materials Science and Technology, University of Crete, Heraklion, Greece
- P399 Synthesis and *in vitro* Bioactivity of Cu and Zn doped sol-gel- silicate bioactive glasses**
J. Bejarano, H. Palza, P. Caviedes
Department of Chemical Engineering and Biotechnology, University of Chile
- P400 A pH-responsive polymer-based drug-delivery platform demonstrating intracellular siRNA target-gene knockdown**
D Roebuck and R Chen
Department of Chemical Engineering, Imperial College London, UK
- P401 Using Simulation to Predict the Thermomechanical behaviour Of the Hydrogel Matrix Applied in Drug Delivery System**
Nirina Santatriniaina, Dominique Pioletti, Lalaonirina Rakotomanana, Mohandrea Nassanjan and Arne Vogel
Mathematical Research Institute, University of Rennes, France
- P402 Using Bioactive Scaffolds to synthesise an *in vitro* 3D Bone Model for Implant Testing**
G. Tetteh, I. U. Rehman and G. C. Reilly
Kroto Research Institute, University of Sheffield, UK
- P403 Bis-urea based supramolecular materials for tissue engineering**
Samaneh Kheyrrooz, Patricia Y.W. Dankers, Rint P. Sijbesma
Laboratory for Macromolecular and Organic Chemistry, Eindhoven University of Technology, The Netherlands
- P404 Biomaterialized hydroxyapatite nanocrystals/graphene oxide as filler for bone tissue engineering**
Maria Grazia Raucci, Daniela Giugliano, Angela Longo, Stefania Zeppetelli, Gianfranco Carotenuto and Luigi Ambrosio
Institute of Polymers, Composites and Biomaterials, National Research Council of Italy, Naples
- P405 Effects on growth and osteogenic differentiation of mesenchymal stem cells by the strontium-added sol-gel hydroxyapatite gel materials**
Maria Grazia Raucci, Daniela Giugliano, M.A. Alvarez-Perez, C. Demitri and Luigi Ambrosio
Institute of Polymers, Composites and Biomaterials, National Research Council of Italy, Naples
- P406 Development of Nerve Guide Scaffold with a Microstructured Intraluminal**
Atefeh Mobasser, Alessandro Faroni, Julie Gough, Giorgio Terenghi, Adam Reid
School of Materials, University of Manchester, UK
- P407 From Bench to bedside: realization of a bioartificial, wearable lung assist device**
Esther Novosel, Annika Wenz, Kirsten Borchers, Markus Schandar, Jörg Schneider, Georg Matheis, Petra Kluger
Novalung GmbH, Heilbronn, Germany
- P408 Gelatin/hydroxyapatite multicomponent system with a modulate biological signals**
Daniela Giugliano, Maria Grazia Raucci and Luigi Ambrosio
Institute of Polymers, Composites and Biomaterials, National Research Council of Italy, Naples
- P409 Osteogenic differentiation induced by biomaterialized gelatin scaffold**
Daniela Giugliano, Maria Grazia Raucci and Luigi Ambrosio
Institute of Polymers, Composites and Biomaterials, National Research Council of Italy, Naples
- P410 Implantable biocomposite based radical oxygen species scavengers as a therapeutic strategy to manage age related macular degeneration**
Marta O. Freitas, Ana S. Neto, B. Moreno, E. Chinarro and Ana P. Pêgo
Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- P411 Soft Matrices vs. Hard Minerals: Biomimetic Morphogenesis of Calcium Phosphate in Lyotropic Liquid Crystals**
Wenxiao He and Martin Andersson
Department of Chemical and Biological Engineering, Chalmers University of Technology, Sweden
- P412 Development of titanium alloy-based scaffold by 3D printing for bone tissue engineering**
Pavan Kumar Srivas, Kausik Kapat, Prabhsh Dadhich
Indian Institute of Technology Kharagpur, West Bengal, India

- P413 Mechanical-stress-assisted rapid cell sheets recovery from poly(*N*-isopropylacrylamide) grafted PDMS surfaces**
Yoshikatsu Akiyama, Miki Matsuyama, Naoya Takeda, Masayuki Yamato and Teruo Okano
 Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Japan□
- P414 The Oceans as a Source and as an Inspiration for Biomaterials Development: Some key examples**
Tiago H. Silva, Alexandre A. Barros, Ana L.P. Marques, Ana Rita C. Duarte, Gabriela S. Diogo, Joana Moreira-Silva, Lara L. Reys, Simone S. Silva, Rui L. Reis
 3B's Research Group, Guimarães, Portugal
- P415 Development and Characterization of Lithium-Releasing Silicate Bioactive Glasses for Bone Repair**
Valentina Miguez-Pacheco, A. Malchere, J. Chevalier and Aldo Boccaccini
 Institute of Biomaterials, University of Erlangen-Nuremberg, Germany
- P416 Effect of magnesium extract on osteoblastic progenitor cells differentiation**
Bérengère J.C. Luthringer, Lili Wu, Frank Feyerabend, Arndt F. Schilling, Regine Willumeit
 Structural Research on Macromolecules, Helmholtz-Centre Geesthacht, Germany
- P417 Fabrication of bilayer nano/microfibrous scaffold for skin tissue engineering**
Pallabi Pal, Pavan Kumar Srivas, Prabhaskar Dadhich, Bodhisatwa Das, Santanu Dhara
 School of Medical Science & Technology, Indian Institute of Technology Kharagpur, West Bengal, India
- P418 Chemical Guiding of Magnetic Nanoparticles in Dispersed Media Containing Poly(methylmethacrylate-co-vinylpyrrolidone)**
Myriam G. Tardajos, Inmaculada Aranaz, Carlos Elvira, Helmut Reinecke, Erhan Piskin, Alberto Gallardo
 Polymer Chemistry and Biomaterials Group, Ghent University, Belgium
- P419 Influence of Surface Roughness Parameters on MG63 Cell Viability: Studies on Laser Microtextured Ti6Al4V Surfaces**
Sumanta Mukherjee, Partha Saha, Santanu Dhara
 Mechanical Engineering Department, Indian Institute of Technology Kharagpur, India
- P420 Extended Release Drug Layer for POSS-PCU Cardiac Stents**
Megan Livingston and Alexander Seifalian
 Division of Surgical and Interventional Sciences, University College London, UK
- P421 Practical Application of Whole Slide Imaging in Biomaterial Science**
C. Brochhausen, H. B. Winther and C. J. Kirkpatrick
 Institute of Pathology, University Medical Centre, Mainz, Germany
- P422 Cryostructured hierarchical scaffolds with zonal biochemistry and anisotropic porosity for biomimetic in situ cartilage tissue engineering**
Kai Stuckensen, Jenny Reboredo, Andrea Schwab, Uwe Gbureck, Heike Walles and Jürgen Groll
 Department for Functional Materials in Medicine and Dentistry, University of Würzburg, Germany
- P423 Additive Manufactured 3D Scaffolds with Tailorable Surface Topography by a Single-Step Method**
SC Neves, C Mota, CC Barrias, PL Granja, L Moroni
 Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- P424 Biodegradable Biopolymer and Calcium Phosphate Composites Manufactured via Impregnation Method**
Marina Sokolova, Janis Locs
 Rudolfs Cimdins Riga Biomaterials Innovations and Development Centre, Riga Technical University, Latvia
- P425 Collagen IV and Fibroblasts as Supportive Factors in Angiogenesis Performed in a Perfusion Bioreactor Setup**
Franziska Kreimendahl, Stefan Weinandy, Julia Frese, Michael Vogt and Stefan Jockenhoevel
 Tissue Engineering and Textile Implants, RWTH Aachen University, Germany
- P426 Asymmetric Biodegradable Scaffolds for Vascular Tissue Engineering**
Patrycja Domalik-Pyzik, Anna Morawska-Chochół, Jan Chłopek, Elżbieta Menaszek, Izabella Rajzer
 Department of Biomaterials, AGH University of Science and Technology, Krakow, Poland
- P427 Biodegradation studies on some magnesium alloys without Al for biomedical application**
Iulian Antoniac, Florin Miculescu, Aurora Antoniac and Ana-Iulia Blajan
 Department Materials Science and Engineering, University Politehnica of Bucharest, Romania
- P428 Glucose sensitive gelation of hydrogel based on hyaluronan-tyramine conjugate**
Lenka Kohutová, Martin Pravda, Julie Bystroňová, Lucie Wolfová, Vladimír Velebný
 Contipro Biotech s.r.o., Dolní Dobruč, Czech Republic
- P429 Surface modification of injectable microspheres for cell therapy applications**
Abdulrahman Baki, Omar Qutachi, Toby Gould, Emily Overton, Kevin Shakesheff and Cheryl Rahman
 Drug Delivery and Tissue Engineering Department, University of Nottingham, UK
- P430 Photocrosslinkable divinyl-fumarate poly-ε-caprolactone for stereolithography application**
A. Ronca, S. Ronca, G. Forte, A. Gloria, R. De Santis, L. Ambrosio
 Institute for Polymers, Composites and Biomaterials, National Research Council of Italy, Napoli, Italy
- P431 Novel radiopaque UHMWPE sublamina wires in a growth-guidance system for the treatment of early onset scoliosis: feasibility in a large animal model**
Alex Roth, Rob Bogie, Paul Willems, Lodewijk van Rhijn, Jacobus Arts
 Department Orthopaedic Surgery, Maastricht University Medical Centre, the Netherlands
- P432 3D Plotting of hydrogels based on fibrillar collagen to create scaffolds with defined inner and outer architecture**
Anja Lode, Kristin Faulwasser, Sophie Brüggemeier, Birgit Hoyer, Hagen Baltzer, Michael Meyer, Claudia Winkelmann, Frank Sonntag, Michael Gelinsky
 Centre for Translational Bone, Joint and Soft Tissue Research, Technische Universität Dresden, Germany

- P433 Porous bioactive glass foam scaffolds: Comparison of 3 compositions**
Amy Nommeots-Nomm, Aine Delvin, Naomi Todd, Robert Law, Hua Geng, Christopher Mitchell, Peter D. Lee, Julian R. Jones
 Department of Materials, Imperial College, London, UK
- P434 Biodegradable nanoparticles coated with hyaluronic acid for targeted and sustained drug delivery to tumors**
Laura Mayol, Marco Biondi, Luisa Russo, Carla Serri, Assunta Borzacchiello, Luigi Ambrosio
 Institute of Polymers, Composites and Biomaterials, National Research Council, Naples, Italy
- P435 Human bone marrow as a unique source of both microvascular endothelial cells and mesenchymal stem cells for vascularised bone tissue engineering**
Julien Guerrero, Hugo de Oliveira, Sylvain Catros, Robin Siadous, Reine Bareille, Mohammed Derkaoui, Didier Letourneur, Joelle Amédée
 Inserm, U1026 Tissue Bioengineering, University of Bordeaux, France
- P436 Effect of Calcium Phosphate Ceramics Substrate Geometry on Mineralization and Cell Organization and Differentiation**
E.R. Urquía Edreira, A. Hayrapetyan, J.G.C. Wolke, J.A. Jansen, J.J.J.P. van den Beucken
 Department of Biomaterials, Radboud University Medical Center, The Netherlands
- P437 Biomechanical & morphological analysis of blend polymeric electrospun scaffolds for Cardiovascular Tissue Engineering**
Alexandros Repanas, Birgit Glasmacher and Dimosthenis Mavrilas
 Laboratory for Biomechanics & Biomedical Engineering, University of Patras, Greece
- P438 Biological interaction between a novel Sr-substituted bone cement and mesenchymal stem cells**
M. Montesj, M. Dapporto, S. Panseri, S. Sprio, A. Tampieri
 Institute of Science and Technology for Ceramics, National Research Council, Faenza, Italy
- P439 In vitro study of the combined effect of hydroxyapatite nanoparticles and lactoferrin in bone homeostasis**
Monica Montesj, Silvia Panseri, Michele Iafisco, Alessio Adamiano, Anna Tampieri
 Institute of Science and Technology for Ceramics, National Research Council, Faenza, Italy
- P440 Fabrication of De-epithelialized Amniotic Membrane/Silk Nanofibre Scaffolds for Skin Tissue Engineering**
Shaghayegh Arasteh, Somaieh Kazemnejad, Mohammad Mehdi Akhondi, Hamed Heidari-Vala, Afsaneh Mohammadzadeh, Sahba Mobini
 Reproductive Biotechnology Research Centre, Avicenna Research Institute, ACECR, Iran
- P441 Bioprinting of vasculature at cell-compatible conditions**
Jing Yang, Kevin Shakesheff
 Division of Drug Delivery and Tissue Engineering, University of Nottingham, UK
- P442 Creating albumin-binding nanostructured surfaces using a thrombin-inhibiting peptide**
Sidónio C. Freitas, Sílvia Maia, Ana C. Figueiredo, Paula Gomes, Pedro J.B. Pereira, Mário A. Barbosa, M. Cristina L. Martins
 Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- P443 Electrochemical deposition of calcium phosphate coatings on Ti6Al4V substrate**
Richard Drevet, Nader Ben Jaber, Ahmed Tara, Joël Faure and Hicham Benhayoune
 Université de Reims Champagne-Ardenne, France
- P444 Soft-matrices based on keratin/alginate for regenerative medicine**
Raquel Silva, Raminder Singh, Bapi Sarker, Judith A. Roether, Iwona Cicha, Joachim Kaschta, Dirk W. Schubert, Rainer Detsch and Aldo R. Boccaccini
 Department Materials Science and Engineering, University of Erlangen-Nuremberg, Germany
- P445 In Vitro Evaluation of Nanohydroxyapatite Biocompatibility in 2D vs 3D Cell Culture Systems**
Aileen Crawford, Abigail Pinnock, Veronika Hruschka, Heinz Redl, Paul V Hatton, Cheryl A Miller
 Bioengineering & Health Technologies Research Group, University of Sheffield, UK
- P446 Engineering of Staple Electrospun Fibres for Biodegradable Nanocomposites by Particle Enhanced Ultrasonication**
E. Mulky, G. Yazgan, K. Maniura-Weber, R. Luginbuehl, G. Fortunato, A. M. Buehlmann-Popa
 Chemistry & Biology, RMS Foundation, Switzerland
- P447 Electrochemically grown mesoporous titania layers**
Sureeporn Uttiya, Daniele Contarino, Sonja Prandi, Maria Maddalena Carmasciali, Ranieri Rolandi, Maurizio Canepa, Ornella Cavalleri
 Department of Physics, University of Genova, Italy
- P448 Characterisation of DNA Interactions with Cationic Polymer Brush**
Mahentha Krishnamoorthy and Julien Gautrot
 School of Engineering & Materials Science, Queen Mary, University of London, UK
- P449 Physicochemical Characterization and In Vitro Hemolysis Evaluation of UV Poly(ethylene glycol) Hydrogels**
M. Flores-Reyes, J. Flores-Estrada, M.V. Dominguez-Garcia, M.S. Camarillo-Romero, M.V. Flores-Merino
 Research Center in Biomedical Science, UAEM, Mexico
- P450 Gold-Containing PMMA Microspheres. A Route to New Highly Radiopaque Cements for Vertebroplasty**
Leo H. Koole, Ketie Saralidze, Eva Jacobs, Alex Roth, and Paul Willems
 Department of Biomedical Engineering, Maastricht University, The Netherlands
- P451 3D Direct Laser Writing of Biomimetic Structures for Osteogenesis Enhancement**
Attilio Marino, Carlo Filippeschi, Barbara Mazzolai, Virgilio Mattoli, Gianni Ciofani
 Center for Micro-BioRobotics, Istituto Italiano di Tecnologia, Pontedera, Italy
- P452 Understanding material properties of 3D poly(ϵ -caprolactone)-based ternary composite scaffolds responsible for highly improved colonization by Human Bone Marrow Mesenchymal Stem Cells**
J. Idaszek, A. Bruinink, J. Rębiś, V. Zell, W. Świąszkowski
 Faculty of Materials Science and Engineering, Warsaw University of Technology, Poland
- P453 The vascularization of porous calcium phosphate ceramics: an in vitro and in vivo study**
Ying Chen, Xiangdong Zhu, Yujiang Fan, Xingdong Zhang
 National Engineering Research Center for Biomaterials, Sichuan University, People's Republic of China

- P454 Thermal Ageing Effect on the Micromechanical Properties of Fiber-Reinforced Composites for Orthopaedic Applications**
Radek Sedláček, Tomáš Suchý, Karel Balík, Zbyněk Sucharda, Zdeněk Padovec
 Department of Mechanics, Biomechanics and Mechatronics, CTU in Prague, Czech Republic
- P455 Fabrication of a Bone Graft Substitute based on a Pre-set Bioactive Glass-Ionomer Cement**
Altair Contreras, Paul V. Hatton, Ian Brook, Abigail Pinnock and Cheryl A Miller
 Bioengineering & Health Technologies Research Group, University of Sheffield, UK
- P456 In vivo Response of Biodegradable Biphasic 3D Printed Scaffolds for Bone Tissue Engineering**
S. Ghanaati, M Barbeck, T. Serra, P. Booms, R. Sader, J. A. Planell, M. Navarro, C. J. Kirkpatrick
 Institute of Pathology, University Medical Center of the Johannes Gutenberg University Mainz, Germany
- P457 Cobalt alloy specific regulation of bone remodelling via HIF: a cause of aseptic orthopaedic implant failure?**
Yutong Li, Johannes Staufenberg, Jay Mashari, Divyahline Logitharajah and Gavin Jell
 Division of Surgery & Interventional Science, University College London, UK
- P458 Trimethyl Chitosan-Based Nanoparticles Intracellular Trafficking and Transfection: a Bioimaging Study**
Aida Varela-Moreira, Carla Pereira Gomes, Maria Gomez-Lázaro, Pedro Miguel Moreno, Ana Paula Pêgo
 Instituto de Engenharia Biomédica, Universidade do Porto, Portugal
- P459 Electrospun Polyvinylpyrrolidone Nanocomposites Mesh with Silica-coated Magnetic Nanoparticles**
Rebecca Zhiyu Yuan, Jian Ping Fan and Jie Huang
 Department of Mechanical Engineering, University College London, UK
- P460 WITHDRAWN**
- P461 Laser surface modification of anodically grown oxide of titanium for biomedical applications**
Diego Pedreira de Oliveira, Laís Tereza Duarte, Adriano Otuka, Claudemiro Bolfarini
 Departamento de Engenharia de Materiais, Federal University of São Carlos, Brazil
- P462 Fibrin-Hyaluronic Acid Interpenetrating Network Hydrogel with Improved Fibrin Stability**
Yu Zhang, Philipp Heher, Sujit. Kotala, Heinz Redl, Jöns Hilborn and Dmitri Ossipov
 Department of Chemistry-Ångström, Uppsala University, Sweden
- P463 Effect of Preconditioning on 70S30C Bioactive Glass Foam Structure and Protein Adsorption**
Gowsihan Poolagasundarampillai, Peter D Lee, Dave Clark, Julian R Jones
 Department of Materials, Imperial College, London, UK
- P464 Synthesis and Characterization of Silicate Glasses with the Sol-Gel Process Containing ZnO or SrO**
G. Theodorou, E. Kontonasaki, K. Chrissafis, L. Papadopoulou, N. Kantiranis, T. Zorba, K.M. Paraskevopoulos, P. Koidis
 Department of Physics, Aristotle University of Thessaloniki, Greece
- P465 Mechanical Stabilisation of Non-Toxic Collagen Fibres for Tendon Repair**
Anna Sorushanova, India Sweeny, Abhay Pandit, Dimitrios Zeugolis
 Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland
- P466 Cell Osteogenic Function Enhancement and Selective Apoptosis by Hydroxyapatite Nanoparticles**
Fangzhu Qing, Zhe Wang, Yanfei Tan and Xingdong Zhang
 National Engineering Research Center for Biomaterials, Sichuan University, P. R. China
- P467 Low Temperature Aqueous Precipitation of Nanocrystalline Hydroxyapatite Containing Strontium and Magnesium for Biomedical Application**
Kristine Salma-Ancane, Liga Stipniece and Liga Berzina-Cimdina
 Rudolfs Cimdins Riga Biomaterials Innovation and Development Centre, Riga Technical University, Latvia
- P468 Controlled release of nucleic acid to enhance bone regeneration**
Bita Sedaghati, Alexander Ewe, Achim Aigner, Michael C. Hacker, Michaela Schulz-Siegmund
 Pharmaceutical Technology, University of Leipzig, Germany
- P469 Determination of Anti-Cancer and Anti-Bacterial Efficacy of Selenium Doped Hydroxyapatite Coating on Titanium Alloy**
Bengi Yilmaz, Zafer Evis, Aysen Tezcaner and Sreeparna Banerjee
 Department of Biomedical Engineering, Middle East Technical University, Turkey
- P470 Microfluidic neuronal circuitry – towards therapies for Huntington’s disease**
Munyaradzi Kamudzandu, Paul Roach and Rosemary A. Fricker
 Institute for Science and Technology in Medicine, Keele University, UK
- P471 Nanoscale Analyses of *Parawixia bistriata* Synthetic Spider Silk Fibres**
Valquíria A Michalczechen-Lacerda, Giovanni R Vianna, André M Murad, Luciano P Silva, Elibio L Rech
 Department of Cell Biology, University of Brasília, Brazil
- P472 Characterization and *In Vitro* Testing of Calcium Phosphate Coatings on Dense and Porous Substrates**
Alexandre Antunes Ribeiro, Roseli Marins Balestra, Mônica Calixto de Andrade, Emanuela Prado Ferraz, Adalberto Luiz Rosa, Paulo Tambasco de Oliveira, Marize Varella de Oliveira
 Powder Technology Laboratory, National Institute of Technology, Brazil
- P473 Synthesis and Characterization of Novel Chitosan Hydrogels for Biomedical Applications**
Krzysztof Pazdan, Kinga Pielichowska, Jan Chłopek
 Department of Biomaterials, AGH University of Science and Technology, Kraków, Poland
- P474 Silver Nanoparticles Modified Titanium for Medical Implants**
Barbara Szaraniec, Magdalena Oćwieja, Marta Kujda and Bartosz Piec
 Department of Biomaterials, Faculty of Materials Science and Ceramics, AGH – University of Science and Technology, Poland
- P475 Synergistic Reinforcement of Poly(e-caprolactone)/Gelatin Nerve Tissue Engineering Scaffolds by Graphene Oxide Nanosheets**
S. Soltanian-Zadeh, Z. S. Ghazali, M. Rabiee, F. Moztarzadeh, M. Mozafari
 Biomedical Engineering Department, Amirkabir University of Technology, Tehran, Iran

- P476 Mechanical reinforcement of chitosan-poly(lactic-co-glycolic) acid scaffolds by 58S bioactive glass**
Katayoun Nazemi, Fathollah Moztarzadeh, Masoud Mozafari
 Biomedical Engineering Department, Amirkabir University of Technology, Iran
- P477 Co-culture of human monocytes and mesenchymal stem cells in order to simulate the bone remodelling processes**
Claudia Kleinhans, Freia Schmid, Franziska Schmid, Petra J. Kluger
 Institute for Interfacial Process Engineering and Plasma Technology, University of Stuttgart, Germany
- P478 Electrospun Poly(ϵ -caprolactone)/Gelatin Scaffold Electrophoretically Coated with Graphene Oxide for Nerve Tissue Engineering**
Z.S. Ghazali, S. Soltanian-Zadeh, F. Moztarzadeh, M. Mozafari
 Biomedical Engineering Department, Amirkabir University of Technology, Iran
- P479 Morphometry of bone tissue around endossal implantation of Hap/TCP granules and autologous mesenchymal cells in rabbits with experimental osteoporosis**
Aleksandrs Grishulonoks, Vita Zalite, Inese Cakstina, Arvids Jakovlevs, Andrejs Skagers
 Department of Oral and Maxillofacial Surgery, Riga Stradins University, Latvia
- P480 A Study On 45S5 Bioglass® Foam Dissolution**
V. Melli, L.-P. Lefebvre, L. Altomare, L. De Nardo
 Dipartimento di Chimica, Materiali e Ingegneria Chimica G. Natta, Politecnico di Milano, Italia
- P481 Biocompatibility of Poly High Internal Phase Emulsion Scaffolds prepared using Stereolithography**
Atra Malayeri, Ilida Ortega, Frederik Claeyssens, Colin Sherborne, Neil R Cameron, Paul V. Hatton
 School of Clinical Dentistry, University of Sheffield, UK
- P482 Implantable hybrid composite for reducing inflammation in age related macular degeneration**
E. Chinarro, L. Pires, Ana P. Pêgo and B. Moreno
 Instituto de Cerámica y Vidrio, CSIC, Madrid, Spain
- P483 Hypoxia inducible factor-1 α (HIF-1 α) stabilization for enhanced cell and tissue construct survival**
Wai Ho, Barry Fuller and Gavin Jell
 Division of Surgery and Interventional Science, University College London, UK
- P484 Practical fixation issues of multifunctional bioresorbable miniplates for osteotomies**
Karol Gryń, Anna Morawska-Chochół, Barbara Szaraniec, Magdalena Ziąbka, Jan Chłopek
 Department of Biomaterials, AGH University of Science and Technology, Krakow, Poland
- P485 Dynamic Surfaces for Stem Cell Differentiation and Retention of Stem Cell Phenotype**
Laura E. McNamara, Jemma N. Roberts, Jugal Sahoo, Karl V. Burgess, Jake Hay, Hilary Anderson, Richard O.C. Oreffo, Rein Ulijn and Matthew J. Dalby
 Centre for Cell Engineering, University of Glasgow, UK
- P486 Cytotoxicity control of SiC nanoparticles introduced into polyelectrolyte multilayer films**
Aldona Mzyk, Roman Major, Bogusław Major
 Institute of Metallurgy and Materials Science, Polish Academy of Sciences, Poland
- P487 Effects of Plasma Electrolytic Oxidation Treatment of Titanium and Titanium-Niobium-Zirconium alloys on Leucocyte Inflammatory Response and Human Osteoblast Mineralization**
Constantin-Edi Tanase, Mehdi Golozar, Kim Hoenderdos, Serena M. Best, Roger A Brooks
 Division of Trauma & Orthopaedic Surgery, Addenbrooke's Hospital, University of Cambridge, UK
- P488 Development of new bioactive phosphate-based glasses and study of the particle size effects on osteoblasts response for bone implant applications**
Martin Stefanic, Xiang Zhang
 Lucideon Ltd., Stoke-on-Trent, UK
- P489 Backside wear in fixed-bearing total knee arthroplasty : the effect of liner locking mechanism and surface roughness of tibial tray**
Łukasz Łapaj, Jacek Markuszewski, Justyna Wendland, Adrian Mróz, Jacek Kruczyński
 Department of General Orthopaedics, Musculoskeletal Oncology and Trauma Surgery, Poznan University of Medical Sciences, Poland
- P490 Paraffin versus frozen sectioning in the histologic evaluation of biomaterial implants – a pilot study**
Volker H. Schmitt, Christoph Brochhausen, Dominic Schwarz, Christine Tapprich, Andreas Mamilos, Helmut Hierlemann, Heinrich Planck, C. James Kirkpatrick
 Institute of Pathology, University Medical Centre, Johannes Gutenberg-University Mainz, Germany
- P491 WITHDRAWN**
- P492 Composition-Property Relationships for Gallium-Borate Glasses**
K. O'Connell, H. O'Shea, Muhammad Hasan, D. Boyd
 Department of Oral Sciences, Dalhousie University, Canada
- P493 RF-Magnetron Sputter Deposited Cap-Based Coatings on the Surface of Titanium**
Maria A. Surmeneva, Roman A. Surmenev, Oleg Prymak, Matthias Epple, Irina I. Selezneva
 Department of Theoretical and Experimental Physics, National Research Tomsk Polytechnic University, Russia
- P494 Electrochemical Surface Treatment for Making Antibacterial Porous Oxide Layer on Ti**
Yusuke Tsutsumi, Naofumi Niizeki, Peng Chen, Maki Ashida, Hisashi Doi, Kazuhiko Noda and Takao Hanawa
 Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University, Japan
- P495 Imaging the structure, dissolution, and bone ingrowth into Bioactive Glass scaffolds**
Peter D. Lee, Taek Bo Kim, Wouter van den Bergh, Hua Geng, Sheng Yue, Christopher Mitchell, Julian Jones
 School of Materials, University of Manchester, UK

- P496 Bioactive hydrogels supporting angiogenesis produced by EB-irradiation**
Bozena Rokita, Slawomir Kadlubowski, Piotr Komorowski, Bogdan Walkowiak, Janusz M. Rosiak
 Institute of Applied Radiation Chemistry, Technical University of Lodz, Poland
- P497 Nanostructured Organic Layers via Polymer Demixing to Control Mesenchymal Stem Cell Response**
Mohammed Khattak, John Hunt and Raechelle A. D'Sa
 Department of Musculoskeletal Biology, Institute of Ageing and Chronic Disease, University of Liverpool, UK
- P498 Role of Gallium doped phosphate-based glasses in the Management of Periodontitis**
Bernadette Lackey, Rohan Sahdev, Quentin Nunes, Tahera Ansari, Susan Higham, David Fernig, Sabeel Valappil
 Department of Health Services Research, University of Liverpool, UK
- P499 Antibacterial TiO₂ nanotubes incorporated with silver nanoparticles**
Zhijun Guo and Li Zhang
 Research Center for Nano-biomaterials, Sichuan University, China
- P500 Bone Nodule Formation by Osteoblast-Like Cells Incubated with a Novel Silane Modification of Glass**
Sandra Fawcett, Nicholas Rhodes, John Hunt and Judith Curran
 Department of Musculoskeletal Biology, University of Liverpool, UK
- P501 Manufacturing of AZ91D Implants with Micro-Scale Features by Powder Metallurgy Route**
Aydin Tahmasebifar, Said Murat Kayhan, Zafer Evis, Yusuf Usta and Muammer Koç
 Engineering Sciences, Middle East Technical University, Turkey
- P502 Nerve Tissue Engineering Using Blends of Polyhydroxyalkanoates**
L.R. Lizarraga-Valderrama and Ipsita Roy
 Faculty of Science and Technology, University of Westminster, London, UK
- P503 Polyethyleneimine-iron oxide hybrid nanomaterials – structure and biocompatibility**
Roxana Mioara Piticescu, Laura Madalina Popescu, Alexandrina Burlacu, Ana-Maria Rosca, Eugeniu Vasile, Andrea Danani
 Laboratory of Nanostructured Materials, National R&D Institute for Non-ferrous and Rare Metals, Romania
- P504 Regulation of Sclerostin Expression by ATP and PTH at Different Stages of Human Bone Development**
Osman M Azuraiddi, Peter J Wilson, Nicholas P Rhodes and James A Gallagher
 UK Centre for Tissue Engineering, Department of Musculoskeletal Biology, University of Liverpool, UK
- P505 Hemocompatible Biomaterial Based on Fibrin Coatings**
Ondřej Kaplan, Tomáš Riedel, Milan Houska, and Eduard Brynda
 Department of Biomaterials and Bioanalogous Systems, Academy of Sciences of the Czech Republic, Prague
- P506 Inflammation-modulating biomaterial impacts neutrophil-monocyte juxacrine and paracrine regulation**
Hannah Caitlin Cohen, Tyler Jacob Lieberthal, W. John Kao
 Pharmaceutical Sciences Division, School of Pharmacy, University of Wisconsin-Madison, USA
- P507 A Heterotypic Microfluidic Model of PDAC Microenvironment for Investigating Stroma-Tumor Interactions and Therapeutic Evaluations**
Cole Drifka, Kevin Eliceiri, Agnes Loeffler, Sharon Weber, W. John Kao
 Department of Biomedical Engineering, University of Wisconsin, Madison, USA
- P508 Enhanced migration of Mesenchymal stem cell spheroids towards glioma**
Smruthi Suryaprakash, Hon Fai Chan and Kam W Leong
 Department of Biomedical Engineering, Duke University, USA
- P509 Feasibility study of developing mosaic and tissue engineering pulmonary valved conduits**
Xiufang Xu, Jinhui Ma, Wenbin Li, Haiping Guo, Sheng Wang, Haifeng Shi, Yi Xin, Xuejun Ren, Zifan Zhou
 Department of Cardiac Surgery, Beijing Anzhen Hospital, Capital Medical University, China
- P510 A Novel Soft Tissue Model for Biomaterial-Associated Infection and Inflammation – Bacteriological, Morphological and Molecular Observations**
Sara Svensson, Margarita Trobos, Maria Hoffman, Birgitta Norlindh, Sarunas Petronis, Jukka Lausmaa, Felicia Suska and Peter Thomsen
 Department of Biomaterials, Sahlgrenska Academy at University of Gothenburg, Sweden
- P511 Pore Structure and Imaging of Collagen- and Elastin-based Scaffolds for Vascular Grafts**
H. Frank, J. Shepherd, S. Best, R. Cameron
 Department of Materials Science and Metallurgy, University of Cambridge, U
- P512 Sustained Release of Naproxen Sodium from Electrospun Aligned PLLA/PCL Scaffold for Tendon Tissue Regeneration**
Yuan Siang Lui, Mark P. Lewis, Joachim Say Chye Loo
 School of Materials Science and Engineering, Nanyang Technological University, Singapore
- P513 Analysis of cells proliferation after dynamic culture on cross-linked synthetic collagen peptide based microcarriers**
M. La Marca and Suzan van Dongen
 Fujifilm Manufacturing Europe, The Netherlands
- P514 Cell Response on the Ti-15Mo alloy Surface after Nanotubes Growth**
Ana Paula Rosifini Alves Claro, André Luiz Reis Rangel, Nathan Trujillo, Ketul C. Popat
 Materials and Technology Department, University of Estadual Paulista, São Paulo, Brazil
- P515 Elaboration of degradable PCL-based shape memory materials**
Thomas Defize, Raphaël Riva, Jean-Michel Thomassin, Michaël Alexandre, Bernard Gilbert and Christine Jérôme
 Center for Education and Research on Macromolecules, University of Liege, Belgium
- P516 Surface immobilization of a green fibronectin-like protein onto cold plasma modified polystyrene substrates**
O. M. Ba, A. Ponche, O. Gallet, P. Marmey, A.C. Duncan, K. Anselme
 Institut de Science des Matériaux de Mulhouse, UMR CNRS 7361, France
- P517 Peptide-Polysaccharide Based Injectable Hydrogel for Sustained Delivery of Active Agents**
Cem Bayram, Ekin Çelik and Emir Baki Denkbaş
 Chemistry Department, Aksaray University, Turkey

- P518 Characterisation of Freeze-Dried Collagen-Fibrinogen Constructs**
Jennifer Shepherd, Charlotte Rasser, Serena Best, Ruth Cameron
 Department of Materials Science and Metallurgy, University of Cambridge, UK
- P519 Nanosized grooves controlling neuronal cell-organization and axonal outgrowth for cochlear implant optimization**
Alexey Klymov, Joost te Riet, John A Jansen and X Frank Walboomers
 Department of Biomaterials, Radboud University Medical Center, Nijmegen, The Netherlands
- P520 The effectiveness of tetra sodium EDTA as an anti-biofilm agent for use in biomaterials**
Steven L Percival and Peter Kite
 Institute of Ageing and Chronic Disease, University of Liverpool, UK
- P521 Composite scaffolds from gelatin and elastin-like block polypeptides for tissue engineering**
Duc H. T. Le, Tatsuya Okubo, Ayae Sugawara-Narutaki
 Department of Chemical System Engineering, The University of Tokyo, Japan
- P522 Pelvic Floor Repair Materials Releasing Vitamin C to Promote Extracellular Matrix Production**
Naside Mangir, Anthony J Bullock, Sabiniano Roman, Nadir Osman, Christopher Chapple, Sheila MacNeil
 Department of Materials Science Engineering, University of Sheffield, UK
- P523 Synthetic collagen peptide based microspheres/ hydrogel hybrid system for bone growth factor delivery**
L. de Miquel, G. van Osch and S.G.J.M. Kluijtmans
 Fujifilm Life Sciences, Tilburg, the Netherlands
- P524 Development of a Novel Composite Polymer Material to Facilitate Regeneration of Chronic Non-Healing Wounds**
Alma Akhmetova, Matthew Illsley, Timur Saliev, Gulsim Kulsharova, Talgat Nurgozhin, Sergey Mikhailovsky, Iain Allan
 Department of Translational Medicine, Longevity and Global Health, Nazarbayev University, Kazakhstan
- P525 The effect of amphiphilic and anionic β -sheet peptides on blood clotting**
Ziv Azoulay and Hanna Rapaort
 Avram and Stella Goldstein-Goren Department of Biotechnology Engineering, Ben-Gurion University of the Negev, Beer - Sheva, Israel
- P526 Processing and Mechanical Properties of Biodegradable β TCP-15Fe15Mg Composites**
Sanjaya K. Swain, Irena Gotman, Elazar Y. Gutmanas
 Department of Materials Science and Engineering, Technion, Haifa, Israel
- P527 Economical Production of Medium Chain Length Polyhydroxyalkanoates**
Yiangos Psaras
 Faculty of Science and Technology, University of Westminster, London, UK
- P528 A New Method to Rapidly Retrieve Encapsulated Cells from Alginate Hydrogels using Pyrophosphate**
David C. Bassett and Pawel Sikorski
 Department of Physics, Norwegian University of Science and Technology, Norway
- P529 Stable Electrospun Hyaluronan Matrices: Production and In Vitro Characterization for the Evaluation as Skin Substitute**
Annalisa La Gatta, Marcella Cammarota, Antonella D'Agostino, Agata Papa, Stefano Guido, Chiara Schiraldi
 Department of Experimental Medicine, Second University of Naples, Italy
- P530 Collagen and PNIPAM Hydrogels: An Injectable Solution to Repair the Knee**
Amanda Barnes, J Lapworth, Mark Coles, Stephen Rimmer and Paul Genever
 Biomedical Tissue Research Group, University of York, UK
- P531 WITHDRAWN**
- P532 Antimicrobial efficacy and biocompatibility of silver-including nanocomposite carbon coatings**
Dorota Bociaga, Piotr Komorowski, Witold Jakubowski, Anna Jędrzejczak, Anna Olejnik
 Division of Biomedical Engineering and Functional Materials, Lodz University of Technology, Poland
- P533 The Impact of Serum, Plasma, and Platelet-Rich Plasma Derived After Exposure to Exercise, Altitude and Recombinant Human Erythropoietin (rHuEpo) on Mesenchymal Stem Cells**
C. Coombs, P. Watt, A. Guildford, G. Bruinvels, Y. Pitsiladis
 Brighton Centre for Regenerative Medicine, University of Brighton, UK
- P534 Towards a 3-Dimensional Model of Neural Tissue with Integrated Recording Sites**
H. Lancashire, C. Pendegrass, A. Vanhoestenbergh and G. Blunn
 Institute of Orthopaedics and Musculoskeletal Science, University College London, UK
- P535 Indirect Prototyped Polyurethane Urea Scaffolds for Cardiac Tissue Engineering**
Roberto Hernandez-Cordova, Donna A Mathew, Alberto Ceballos-Villanueva, Hugo J Carrillo-Escalante, Araida Hidalgo-Bastida, Fernando Hernandez-Sanchez
 Manchester Metropolitan University, UK
- P536 RF Magnetron Sputtering of Multicomponent Ion Doped Phosphate Glasses**
Bryan Stuart, M. Gimeno-Fabra, D. Grant, I. Ahmed and J. Segal
 Department of Mechanical, Materials and Manufacturing Engineering, University of Nottingham, UK
- P537 Manufacture of Bioresorbable Fibre Reinforced Composites for Fracture Fixation Devices**
Fernando Barrera Betanzos, Miquel Gimeno-Fabra, Joel Segal, David Grant and Ifty Ahmed
 Department of Mechanical, Materials and Manufacturing Engineering, University of Nottingham, UK
- P538 Development of a Soft Tissue in vitro Model for Ameloblastoma**
T. Eriksson, S. Fedele, R. Day, V. Salih
 Eastman Dental Institute, University College London, UK
- P539 Porous Electrospun PCL fibres for Osteo-Differentiation**
Selene Alcantara-Barrera, Zandra Flores, Ricardo Vera-Graziano, Alfredo Maciel-Cerda, L. Araida Hidalgo-Bastida
 Manchester Metropolitan University, UK

P540 Atomic Layer Deposition of Silver on High Aspect Ratio Structures for Medical Implants

Zahra Golrokhi

Department of Materials Science and Engineering, University of Liverpool, UK

P541 Characteristics and Cytocompatibility of Novel Borophosphate Glasses

Chenkai Zhu, Ifty Ahmed, Xiaoling Liu, Andy Parsons, Jingsong Liu, Chris Rudd

Division of Materials, Mechanics and Structures, University of Nottingham, UK

YSF Rapidfire Presentation Programme

Rapidfire Session I Hall 2, Sunday 31st August 12:30 - 13:30

Chairs: Nicholas Bryan, University of Liverpool
Theun van Veen, University of Liverpool
Lorenzo Moroni, University of Twente
Sandra van Vlierberge, University of Gent
Anna-Finne Wistrand, KTH Royal Institute of Technology

- 1-1 Carlos Elias**
Mechanical Properties of Zirconia 3-Unit Fixed Dental Prostheses Machined on a CAD/CAM System
- 1-2 Sandra Fawcett**
Bone Nodule Formation by Osteoblast-Like Cells Incubated with a Novel Silane Modification of Glass
- 1-3 Annika Jokinen**
MP-SPR New characterization method for interactions and ultrathin films
- 1-4 Prabhjeet Kaur Dhillon**
Nanoscale Roughness Influences on Cell Proliferation
- 1-5 Kasai Nahoko**
Neuronal growth on nano-pillar substrates
- 1-6 Annabelle Chan**
Patient Specific Implants Using a Novel Rapid Template Approach
- 1-7 Stéphanie Metzger**
Mobilization of Mesenchymal Progenitor Cells to Improve Bone Healing
- 1-8 Febriyani Damanik**
Incorporation of Elastin Enhancement Agents on Nano-scale Fibers
- 1-9 Helena Grady**
Central Venous Catheters Functionalised with Chlorhexidine-Hexametaphosphate Nanoparticles for Prolonged Anti-Biofilm Efficacy
- 1-10 Gloria Huerta-Angeles**
Development of a new biomaterial based on Hyaluronan and oleic acid for drug delivery applications
- 1-11 Natalie Wood**
Chlorhexidine-based Antimicrobial Nanoparticles as a Coating for Dental Implants
- 1-12 Matteo Gherardi**
Plasma assisted production of residual solvent free PLLA electrospun scaffolds
- 1-13 Irina Batenina**
A comparison of two approaches to the formation of antibacterial surfaces: doping with bactericidal element vs drug loading
- 1-14 Lorena del Rosario Lizarraga Valderrama**
Nerve Tissue Engineering Using Blends of Polyhydroxyalkanoates
- 1-15 Ąukasz Ąapaj**
Backside wear in fixed-bearing total knee arthroplasty : the effect of liner locking mechanism and surface roughness of tibial tray
- 1-16 Danielle Cabral**
Candida glabrata in mouthwash -coated endotracheal tubes: antibiofilm activity by electronically scanning microscopy
- 1-17 Prabhhash Dadhich**
Nano-Micro Architectural Hybrid Composite Scaffold for Bone Tissue Engineering
- 1-18 Diego de Oliveira**
Laser surface modification of anodically grown oxide of titanium for biomedical applications
- 1-19 Matteo D'Este**
Amidation via DMTMM: A New and Efficient Method for Hyaluronan Biomaterials Preparation
- 1-20 Ting Diu**
Bactericidal and cell compatible titanium surfaces with TiO₂ nanowires
- 1-21 Cyrine Dridi**
Design of Biomimetic Fibronectin Fragment Used in Multi-layer Film Coating for Tissue Engineering
- 1-22 Matthias Schumacher**
Strontium-substituted CaP bone cements for the treatment of osteoporotic bone defects
- 1-23 Farzad Foroutan**

ORAL PRESENTATIONS

A Viscoelastic, Anisotropic, Hyperelastic Model of the Human Cornea

Charles Whitford^{1*}, Natasha Movchan² and Ahmed Elsheikh^{1,3}

^{1*}School of Engineering, University of Liverpool, UK, whitford@liv.ac.uk

²Department of Mathematical Sciences, University of Liverpool, UK

³National Institute for Health Research (NIHR) Biomedical Research Centre, Moorfields Eye Hospital NHS Foundation Trust and UCL Institute of Ophthalmology, London, UK

INTRODUCTION

Numerical simulation of the cornea's mechanical performance has led to improvements in the design of diagnostic and corrective procedures for degenerative visual conditions such as Keratoconus¹. Accurate simulations require close representation of in-vivo conditions including the tissue's response to strain. The main contribution to mechanical stiffness is provided by the collagen fibrils embedded within the stroma. Over recent decades the accuracy of simulations has improved significantly with developments in fibril anisotropy representation^{2,3}. Wide angle x-ray scattering (WAXS) characterised microstructural relationships and identified that stiffness increased with fibril density⁴. In this paper, we present a constitutive model which represents stromal viscoelasticity, hyperelasticity, shear stiffness, regional variation of collagen fibril anisotropy and density, through-thickness fibril density and angular distribution, fibril cross-linking, extra-fibrillar matrix and age-related stiffening. The model has been calibrated with an extensive experimental database providing representative numerical parameters.

EXPERIMENTAL METHODS

Experimental data from 128 human donor eyes has been used in this study. The data includes WAXS data on fibril anisotropy and density, second harmonic-generated cross-section images leading to through-thickness angular distribution of fibrils, and both tissue shear and inflation tests which provided measurements of deformation vs. loading relating to stress-strain behaviour. Visual representation of the anisotropic and density relationships within the model is provided in Figure 1.

Material representation has been developed as a constitutive model based on continuum mechanics theory. This model was incorporated within finite element analysis (FEA) for the non-linear finite element solver Abaqus/Standard 6.13. Numerical parameters have been derived through an inverse analysis approach to represent the cornea at ages 40-100 years.

RESULTS AND DISCUSSION

The results simultaneously represent multiple loading scenarios (shear & inflation) and multiple strain-rates with the differences between numerical predictions and experimental data remaining below 5%.

Table 1. Tangent modulus/stiffness (E) at a selection of locations within the cornea. Values represent the stiffness at 0.02 logarithmic strain and a slow strain-rate. Key: Vertical (V), Diagonal (D), Latitudinal (La), Longitudinal (Lo) and Shear (S); reference location numbers found in Fig. 1.

Location reference	1	2	3	4	5	6	7	8	9	10	1
E(KPa)	979	541	959	894	1171	490	459	584	669	494	30
Direction	V	D	La	La	La	Lo	Lo	Lo	La	Lo	S

These results quantify previous observations which reported that the mechanical response of the cornea is significantly affected by its microstructural arrangement and viscoelastic behaviour.

CONCLUSION

Consideration of the microstructure of the stroma has improved the accuracy of numerical simulations of the mechanical behaviour of the cornea. The introduction of combined viscoelastic and anisotropic representation has particular benefit when modelling surgery, microstructure scarring, and high-speed tonometers such as the Ocular Response Analyzer and the Corvis. Work is being extended to represent the behaviour of the human sclera. While this model has been developed to represent the cornea, the methodology is adaptable for other collagenous soft tissues.

Figure 1. Output from numerical simulation representing the regional variation of fibrils across the cornea. Anisotropic weighting for each angle at each integration point was combined to form individual plots of local distribution. Directional related stiffness is a combination of the local anisotropic distribution and density. Numbered arrows are used for reference in Table 1.

INTRODUCTION

Age-related macular degeneration (AMD) is the leading cause of blindness among the elderly in industrialized countries¹⁻². Healthy stem cell derived retinal pigment epithelium (RPE)—like cells delivered as an integer epithelial sheet on a carrier substrate, represent a promising approach for RPE replacement in AMD²⁻⁴. An optimal substrate should simulate RPE natural microenvironment and maintain its phenotype, allow nutrient flow or biodegrade rapidly, among others^{2,4}. Bacterial cellulose (BC) is an interesting biomaterial for tissue regeneration applications, presenting unique structural and mechanical properties, biocompatibility, non-toxicity, high hydrophilicity, transparency and permeability for gas and fluid exchange⁵⁻⁸. In this work, we evaluated if RPE cells were able to adhere and proliferate on BC, to assess its feasibility as a novel substrate for RPE transplantation. BC substrates were also characterized according to surface and bulk properties relevant for this application. BC surface was modified via surface acetylation and polysaccharide adsorption, using chitosan and carboxymethyl cellulose, to obtain different surface profiles (ABC, CBC and CMBC) that affect differently RPE cell response^{9,10}.

EXPERIMENTAL METHODS

BC was produced in static cultures of *Gluconacetobacter xylinum*. Water contact angles were measured using the sessile drop method to assess surface hydrophobicity. Diffusion experiments were performed to evaluate substrate permeation. Substrates with known permeability (reference) were used to enable comparison and the solutes used were PEG 35 and 300 kDa. BC substrates were analysed for endotoxin using the limulus amebocyte lysate test. HTERT-RPE1 cells were seeded in BC and tissue culture polystyrene (TCP) at a density of 40 000 cells/cm². Cell viability and proliferation were evaluated using the MTS assay and LIVE/DEAD fluorescence microscopy after 3, 7, and 14 days.

RESULTS AND DISCUSSION

BC, CBC and CMBC presented a similar hydrophilic degree with contact angles ranging from 20 to 25°. ABC substrates decreased surface hydrophilicity to 65°. The permeation coefficients of permeable substrates were 4.2×10^{-6} and 3.8×10^{-6} cm²/s, for PEG 35 and 300 kDa, respectively. BC substrates presented permeation coefficients in the range $2.5 - 3.4 \times 10^{-6}$ and $1.3 - 2.2 \times 10^{-6}$ cm²/s, for PEG 35 and 300 kDa, respectively. The differences observed among permeable and BC substrates were not significant suggesting that BC is permeable and allows fluid transport. Substrates remained stable for up to 3 months

although some swelling was observed with 5, 2, 6 and 8 times its dry weight in water for BC, ABC, CBC and CMBC substrates, respectively. The endotoxin levels measured for BC, ABC, CBC and CMBC substrates were 34.0 ± 11.7 , 4.4 ± 0.4 , 31.8 ± 2.7 and 26.6 ± 17.9 mEU/device, respectively. These levels are much lower than the limit of 20 EU/device, established by the FDA for medical devices¹¹. Through viability assays it was possible to observe the formation of a cell monolayer in TCP after 7 days. Similarly, cell monolayers were observed in ABC substrates after 14 days. The other modified BC substrates presented lower initial cell adhesion, however with similar proliferation rates as in ABC. The unmodified BC showed low initial cell adhesion and no cellular proliferation.

CONCLUSION

BC modification was essential for the adhesion and proliferation of hTERT-RPE1 cells. ABC substrates showed improved properties comparing to the other modified substrates, with less swelling and lower levels of endotoxins and hydrophilicity that lead to a better initial cell adhesion. Therefore, BC seems to be an interesting substrate for RPE adhesion and proliferation. However, other studies should be performed to further confirm BC feasibility as substrate for RPE transplantation. Additionally, alternative surface modifications can be considered to further improve cell adhesion, such as the adsorption of specific proteins.

INTRODUCTION

Glaucoma is a blinding eye disease characterised by a high intraocular pressure with associated optic neuropathy.¹ It is estimated to affect 66 million people worldwide and is a leading cause of blindness.² The mainstay of treatment uses eye drops to deliver ocular antihypertensive drugs into the eye. These lower the intraocular pressure (IOP), but do not target the underlying pathology – that includes fibrosis of the main drainage portal, the trabecular meshwork (TM). The fibrogenic cytokine TGF β has been implicated in the aetiology of TM fibrosis.³ Decorin is a proteoglycan that attenuates fibrotic scarring by sequestering TGF β 1&2, directly binding to collagen and limiting fibrillogenesis and initiating fibrolysis by inducing matrix metalloproteinases against matrix molecules in both established and nascent scars.⁴ Decorin reduces TM scarring in a rat model of TGF β -induced raised IOP by reversing established fibrosis and therefore lowering the IOP. However, administration of Decorin involved bi-weekly intracameral injections that have poor translational potential. Synthetic short sequence peptide delivery vehicles easily penetrate the cornea and can be used as carriers to deliver proteins into the anterior chamber of the eye. These peptides are designed with multiple positive charges that modify the permeability of the peptide-protein complex to the corneal epithelium and the posterior corneal endothelium and are termed 'Nanosomes'. They allow active drugs attached to the peptides to access the anterior chamber of the eye.

The aim of this work is to utilise the cell penetrating ability of the Nanosomes to deliver Decorin into the anterior chamber of the eye to treat TM fibrosis in a rat model of glaucoma.

EXPERIMENTAL METHODS

Nanosomes were synthesised using standard solid phase peptide synthesis and Fmoc chemistry. The final product was purified by HPLC and characterised by mass spectrometry. Decorin was bound to the nanosomes by incubation in sterile PBS at room temperature.

In vivo experiments were carried out on male Sprague-Dawley (SD) rats weighing 175-250g under a 12 hour light and dark cycle with food and water *ad libitum*. Anaesthesia was induced under 5% isoflurane/1.5 L per minute of O₂ and maintained at 3% during surgery. Under anaesthesia, biweekly intracameral injections of TGF β 2 were given to 6 rats to induce fibrosis of the TM and raise IOP. IOP was measured every 3 days. After 3 weeks with maintained high IOP, Decorin-Nanosome drops were administered twice daily, topically to the cornea. After 5 weeks of treatment the animals were killed and perfused with 4% paraformaldehyde. The

ocular tissues were harvested for immunohistological analysis.

RESULTS AND DISCUSSION

The Nanosomes successfully entered the anterior chamber of the eye both alone and when complexed with Decorin. Each eye drop was able cross the cornea in 6 minutes (Figure 1) and delivered 17.9 \pm 3 ng/ml Decorin into the anterior chamber as measured by ELISA of aqueous humour; Decorin was also found in the posterior segment of the eye, SD rats with TGF β 2-induced raised IOP (16 mm/Hg) treated for 2 weeks with an eye drop formulation of the Decorin-Nanosome complexes had IOP lowered to normal levels (11mm/Hg).

Figure 1 Optical Coherence Tomography images of Decorin-Nanosome complexes crossing the cornea of a SD rat A) at time 0 and B) after 6 minutes.

CONCLUSION

Nanosomes are simple biocompatible carriers, that allow the delivery of large therapeutic proteins across epithelial membranes. We have successfully used them to deliver anti-fibrotic proteoglycans into the eye and have shown their efficacy at treating raised IOP in a rat model of glaucoma. This work has translational potential to be brought forward as a novel ocular drug delivery vehicle.

Emulation of Extracellular Matrix for the Development of Human Corneal Stromal Substitute

Pramod Kumar,¹ Abhigyan Satyam,¹ Xingliang Fan,¹ Brian Rodriguez,² Yuri Rochev,¹ Michael Raghunath,^{3,4,5} Abhay Pandit¹ and Dimitrios Zeugolis¹

¹Network of Excellence for Functional Biomaterials, National University of Ireland, Galway, Ireland, ²Conway Institute of Biomolecular & Biomedical Research, University College Dublin, Dublin, Ireland, ³Department of Bioengineering, Faculty of Engineering, ⁴Life Science Institute, ⁵Department of Biochemistry, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, p.kumar1@nuigalway.ie

INTRODUCTION

Scaffold free cell-based therapies are potential approaches to avoid various deleterious effect of foreign material based scaffold. However, very few products have been reached to the clinics due to prolong culture time required¹. The keratocytes required 35-84 days culture to build a cohesive stromal substitute, which is poor in extracellular matrix (ECM) and thinner than the native tissue^{2,3}. The macromolecular crowding (MMC), the addition of inert macromolecules in culture media, can accelerate the cell specific ECM deposition within 2-6 days of culture, without change in cell phenotype⁴. Herein, the role of MMC on human corneal fibroblasts (HCFs) has been demonstrated, which were cultured on a NIPAAM based thermosensitive copolymer to generate ECM-rich HCFs cell sheets.

EXPERIMENTAL METHODS

HCFs cultured under MMC (100µg/ml dextran sulphate (DxS); and 50µg/ml Carrageenan (CR)). The ECM deposition was analysed by SDS-PAGE, immunocytochemistry (ICC) and proteomic analysis. Gene expression was assessed using the RT-PCR. Intact HCFs cell sheets were developed using NIPAAM/n-tert butyl acrylamide thermal responsive polymer.

RESULTS AND DISCUSSION

Densitometric analysis of SDS-PAGE and immunocytochemistry shows that MMC (DxS and CR) significantly increased collagen I deposition ($p < 0.05$) and more ordered ECM deposition. Immunofluorescence confirmed the enhanced ECM in the presence of MMC. Proteomic and genomics analysis confirmed the increase in stromal ECM/total proteins and phenotype maintenance respectively (results not shown). Successful detachment of HCFs cell sheet was demonstrated at low temperature after MMC, which showed the transparency similar to the control samples and high ECM deposition was confirmed using various techniques.

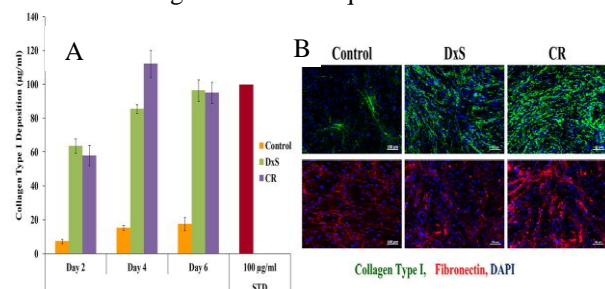

Fig. 1. (A) The densitometry for collagen type I at day

2, 4 and 6 (B) The immunofluorescence for collagen type I and fibronectin (C) at day 4 of MMC.

Fig. 2. The characterization of developed cell sheet using CR as a macromolecular crowding agents at day 4 (A) The trichrome staining for ECM (B) Picro-sirius red staining after MMC (C) Collagen type I immunofluorescence of cell sheet (D) Collagen type V immunofluorescence of cell sheet (E) Transmittance of the developed HCFs cell sheet demonstrated that there is no change in transmittance of cell layer after MMC (F) AFM analysis of HCFs confirmed the presence of collagen ECM in CR treated samples.

CONCLUSION

MMC of HCFs with DxS and CR significantly accelerates corneal specific ECM deposition without influencing the basic characteristic. The process also favours the development of ECM rich HCFs cell sheets using CR within 4 days. The thermal responsive copolymer allowed the detachment of intact, transparent and native ECM rich corneal stromal tissue substitute.

Nanostructured materials for tissue engineering: nanofibres, nanoparticles and nanofilms

Lucie Bacakova

Department of Biomaterials and Tissue Engineering, Institute of Physiology, Academy of Sciences of the Czech Republic, Videnska 1083, 142 20 Prague 4, Czech Republic; E-mail: lucy@biomed.cas.cz

INTRODUCTION

Bioartificial tissue replacements contain a cell component and a material component, which serves as a carrier for anchorage-dependent cells. The material component should actively promote the adhesion, growth, differentiation, phenotypic maturation and other cell functions in a controllable manner. The cell performance on the materials can be markedly improved by its nanostructure (i.e., nanoscale surface roughness or nanofibrous structure), which mimics the nanoarchitecture of the natural extracellular matrix.

EXPERIMENTAL METHODS

In the first part of this study, we have focused on fibrin nanofibrous layers prepared *in vitro* by a controlled simulation of a part of the physiological hemocoagulation process [1]. The layers were intended for inner coating of synthetic vascular grafts in order to improve their endothelialization.

In the second part, we have constructed (by electrospinning technique) synthetic nanofibrous scaffolds made of poly (L-lactide) (PLLA) or poly (lactide-co-glycolide) (PLGA) reinforced with hydroxyapatite or diamond nanoparticles for potential use in bone tissue engineering [2, 3].

Finally, we have created nanocrystalline diamond films for potential surface modification of metallic bone implants [4].

RESULTS AND DISCUSSION

The resulting fibrin layers were of various morphology, i.e. thin and thick, two- or three-dimensional, with short and sparse or long and dense fibrin nanofibers (Fig. 1A). Thick three-dimensional films supported cell-matrix and cell-cell adhesion of vascular endothelial cells, which was manifested by well-developed talin-containing focal-adhesion plaques (Fig. 1B), immunofluorescence of VE-cadherin at the cell edges (Fig. 1C) and formation of a confluent endothelial cell layer.

Fig. 1. A nanofibrous fibrin layer for inner modification of vascular prostheses (A), and immunofluorescence of talin (B) and VE cadherin (C) in endothelial CPAE cells in cultures on these layers. Bar 10 μm (A) or 25 μm (B, C).

Addition of diamond or hydroxyapatite nanoparticles to synthetic polymeric nanofibrous meshes improved some mechanical properties of the scaffolds (2, 3) and

supported the adhesion and growth of human bone-derived cells (Fig. 2). Scaffolds reinforced with 15 wt. % of hydroxyapatite increased the production of osteocalcin, i.e. an important marker of osteogenic cell differentiation, in these cells [3].

Fig. 2. Nanofibrous PLGA scaffolds reinforced with 23 wt% of nanodiamond (A), human osteoblast-like MG 63 cells in cultures on these scaffolds (B) and on PLLA scaffolds with 15 wt. % of hydroxyapatite nanoparticles (C). SEM microscopy (A), staining with Texas Red-C₂-Maleimide and Hoechst #33342 (B), immunofluorescence of osteocalcin (C). Bar 10 μm (A), 50 μm (B) or 20 μm (C).

Nanocrystalline diamond films also supported the adhesion, growth and osteogenic differentiation of human bone-derived cells, which was more apparent on more hydrophilic O-terminated films (Fig. 3) [4].

Fig. 3. Nanocrystalline diamond film (A) and human osteoblast-like Saos-2 cells in cultures on these films terminated with H (A) and O (B). AFM microscopy (A), immunofluorescence of talin combined with phalloidine staining of F-actin (B, C). Bar=20 μm .

CONCLUSION

All tested nanostructured materials, particularly thick nanofibrous fibrin films, nanofibrous PLLA scaffolds with 15 wt.% of hydroxyapatite and O-terminated nanocrystalline diamond films supported the adhesion, growth and phenotypic maturation of cells.

In bone tissue engineering approach, fabrication of scaffold and so the selection of materials have critical importance. Here, we describe two new biopolymers silk fibroin and citrus pectin based new functional scaffold fabrication.

INTRODUCTION

In construction of tissue engineered constructs, the scaffold plays a crucial role on regeneration of damaged tissue in body. Therefore the scaffold fabrication techniques and the selection of materials are critical decisions. In tissue engineering, both biologically and synthetic derived materials are studied. In general, biologically derived materials have an advantage because of their inherent properties like biocompatibility and adequate mechanical property¹. Silk fibroin and high methoxyl citrus pectin are natural derived structural biopolymers. Their biocompatibility, mechanical stability and properties as material are noteworthy. Both biopolymers were previously studied in bone tissue engineering individually^{2,3}. However fibroin and pectin have not been used together for scaffolding. In this study, silk fibroin and pectin are chemically crosslinked (carbodiimide crosslinking) and scaffold fabricated for the first time.

EXPERIMENTAL METHODS

Preparation of Silk fibroin and Citrus pectin solutions

Native *Bombyx mori* silk fibroin was degummed with 0.02 M NaHCO₃ solution at 100°C for 30 min. The degummed silk fibroin was dissolved LiBr solution at 60°C for 4 h. After dialysing for 2 days, the silk fibroin solution was filtered⁴. High methoxyl citrus pectin was dissolved in d H₂O and the reaction solvent was d H₂O

Preparation Silk fibroin/Pectin blend scaffolds

Silk fibroin and HMP was mixed with same amount of NaHCO₃ individually. For carboxylation of hydroxyl groups,, 5-fold excess of succinic anhydride was dissolved in DMF and added to fibroin and pectin solutions.

The reaction solutions were mixed in a flask and stirred for overnight. After blending of two modified fibroin and pectin, 4-fold molar excess of EDC to carboxyl groups was added. Ethylene diamine was then added drop wise under magnetic stirring, in ~10-fold molar excess to carboxyl group. The solution pH was adjusted to 6-7 and was monitored for 30 min. The solution was then poured into a petri plate for gelling and lyophilized after freezing at -80°C overnight for preparation of porous scaffolds. After crosslinking, the scaffolds were washed in distilled water to remove unreacted linker and crosslinker (Fig.1). FTIR and ¹H-NMR were done for confirmation..

RESULTS AND DISCUSSION

FTIR and ¹H-NMR analysis were performed to prove the carbodiimide facilitated amide bond formation between citrus pectin and silk fibroin.

CONCLUSION & FUTURE WORK

By this method, silk fibroin and high methoxylated citrus pectin were crosslinked and studied for the first time for biomedical study. The in vitro studies will be performed for these scaffolds. To enhance the crosslinking and cellular compatibility, new methods of crosslinking will be tried.

INTRODUCTION

It was reported that chondrocyte aggregation in spheroids prevented dedifferentiation of chondrocytes. However, if the diameter of the spheroids increased, necrosis may occur in the center of the spheroids due to lack of nutrient. Therefore, regulation of spheroid size is important to maintain nutrient supply into the center of the spheroid. Since we reported that mouse fibroblasts spheroids with uniform size were formed using proline-containing periodic peptides H-(Lys-Pro)₁₂-OH (KP24), it is considered that size of chondrocyte spheroids can be regulated using KP24. Therefore, the purpose of this study is to produce uniform chondrocyte spheroids using KP24 to prevent central necrosis in the spheroids.

EXPERIMENTAL METHODS

Preparation of chondrocyte spheroids: Chondrocytes were isolated from articular cartilage of femur of 6-month-old pig. Dulbecco's modified Eagle's medium supplemented with 10% bovine serum and ascorbic acid was prepared as culture medium. KP24 was added to the culture medium at concentrations of 0, 0.25, 0.5, and 1.0 mg/ml. Chondrocytes were seeded in 96-well plates at cell density of 1.5×10^5 cells/cm². Chondrocytes were cultured in the culture medium with KP24 for 3 days, and then chondrocytes were cultured in the culture medium with KP24 (KP24(+ +)) or without KP24 (KP24(+ -)) to investigate the effect of duration of KP24 supplementation on formation of spheroids for 4 more days. Morphology observation of spheroid, viability assay of chondrocytes in spheroid, and measurement of glycosaminoglycan (GAG) amount were performed after 3, 5 and 7 days of cultivation.

Evaluation of chondrocyte spheroids: Morphology of spheroid was observed using a phase contrast microscope. Equivalent circle diameter was calculated as the diameter of spheroid. In this study, cell aggregate with more than 30 μ m in diameter was defined as spheroid. The viability of chondrocytes was evaluated by observing spheroids stained with fluorescent reagents using a fluorescence microscope. GAG amount was measured using the DMMB method.

RESULTS AND DISCUSSION

Figure 1 shows microscopic images of spheroids for KP24(+ +) and KP24(+ -) at KP24 concentration of 0.5 mg/ml. Though fusion of spheroids was observed after 7 days of cultivation in the case of KP24(+ +) (Fig.1(c)), the spheroids grew larger with cultivation days in the both case. In the case of KP24(+ -), fusion of spheroids was prevented and uniform spheroids were formed after 7 days of cultivation (Fig.1(f)). Same tendency was observed in all KP24 concentration, but high KP24 concentration resulted in more rapid formation of

spheroids. The GAG amounts of the spheroids in one well increased with increasing KP24 concentration after 5 and 7 days of cultivation. According to fluorescent microscopy, number of dead cells remarkably increased in the spheroids when the diameter of spheroids was over 200 μ m. Figure 2 shows change in the diameter of the spheroids for KP24(+ -) with cultivation days. The average diameter of spheroids increased and the number of spheroids decreased with cultivation days. After 7 days of cultivation, the average diameter of spheroids for KP24(+ -) at concentration of 0, 0.25, 0.5, and 1.0 mg/ml were 232, 215, 308, and 261 μ m respectively, and the number of spheroids for KP24(+ -) at KP24 concentration of 0, 0.25, 0.5, and 1.0 mg/ml were 86, 100, 58, and 53 respectively. The number of spheroids with about 200 μ m in diameter became highest at KP24 concentration of 0.25 mg/ml. These results showed that uniform spheroids with about 200 μ m in diameter were obtained so as to prevent necrosis by changing duration of KP24 supplementation at KP24 concentration of 0.25 mg/ml.

CONCLUSION

Size of uniform spheroids was regulated to about 200 μ m in diameter in the case of KP24(+ -) at KP24 concentration of 0.25 mg/ml.

Fig. 1. Photos of chondrocyte spheroids (0.5 mg/ml). (a) KP24(+ +) at day 3. (b) KP24(+ +) at day 5. (c) KP24(+ +) at day 7. (d) KP24(+ -) at day 3. (e) KP24(+ -) at day 5. (f) KP24(+ -) at day 7.

Hyaluronic Acid Based-Hydrogels Attenuate Inflammatory Receptor and Neurotrophins in IL-1 β Induced Inflammation Model of Nucleus Pulposus Cell Cultures

Isma-Liza Mohd-Isa, David Tiernan, Akshay Srivastava, Peter Rooney and Abhay Pandit

Network of Excellent Functional Biomaterials, National University of Ireland, Galway, Ireland

I.MOHDISA1@nuigalway.ie

INTRODUCTION

Low back pain is associated with degeneration of Intervertebral Disc (IVD). Previous studies have shown that local production of neurotrophins stimulated innervation in degenerated IVD¹. High Molecular weight (HMw) Hyaluronic Acid (HA) is a potential therapeutic biomaterial for inflammatory pain of IVD as it exhibits anti-inflammatory effect and provides a better conducive microenvironment for IVD cells. The hypothesis of the study was that HA hydrogels alter inflammatory receptor and neurotrophins expression in IL-1 β induced inflammation model of NP cell culture. Specifically, to test this hypothesis an HA hydrogel system was developed and characterised for cytotoxicity and *in vitro* degradation. We further determined the effect of HA hydrogels in IL-1 β induced inflammation model in NP cell cultures by investigating activation of receptors IL-1R1, MyD88, CD44 and also examined protein and mRNA expression of neurotrophins {Nerve Growth Factor (NGF) and Brain Derived Neurotrophic Factor (BDNF)}.

EXPERIMENTAL METHODS

HA hydrogels were synthesized by using 7.5mg sodium HA Mw 1.2×10^6 Da (Lifecore Biomedical, USA) dissolved in 1mL distilled water and crosslinked with 150mg 4-arm PEG amine Mw 2000Da (Jenkem Tech, TX, USA). N-hydroxysuccinimide (NHS) (150mg) and 1-Ethyl-3-[3-(dimethylamino)propyl]carbodiimide (EDC) (100 μ L) were added to functionalise the carboxyl group of HA molecules². The sphere-shaped hydrogels were obtained through a pipetting a channel volume of 5 μ L onto a hydrophobic modified glass slide (TeflonTM, Fisher Scientific, Ireland) and incubated for three hour at 37°C to allow crosslinking reaction to complete. The gelation time of HA hydrogels was measured. The *in vitro* degradation of HA hydrogels with hyaluronidase and PBS was assessed at 1, 2, 3, 7, 14 and 21 days. The potential cytotoxicity was assessed against ADSCs by alamarBlue[®]. NP cells were isolated from disc T9-S1 of bovine tails and cultured for 10 to 20 days. The NP cell viability and distribution in 2D culture was examined for 24, 48 and 72 hours using Live/Dead[®] staining kit. The 5×10^3 cells were stimulated with IL-1 β (10ng/ml) to create an inflammatory milieu and treated with 100 μ L (5 μ L \times 20) hydrogels for day 1, 3 and 7. Activation of receptor IL-1R1, MyD88 and CD44 were determined by immunofluorescent imaging. Neurotrophins expression of NGF and BDNF were measured by ELISA and qPCR.

RESULTS AND DISCUSSION

The *in situ* gelation time for the formation of spherical shaped hydrogels were 5.5 minutes and the developed

hydrogels were stable at 4°C. Preliminary data of cytotoxicity study showed metabolic activity of ADSCs in presence of 100 μ L hydrogels ($94.75 \pm 1.18\%$, $94.02 \pm 14.10\%$, $97.95 \pm 4.69\%$) and over 73% ADSCs metabolic activity was observed in presence of 200 μ L hydrogels after 24, 48 and 72 hours in culture (Fig. 1.A). Inflammatory receptor IL-1R1 was down-regulated after treating with HA hydrogels in inflammation model of NP cell cultures (Fig. 1.C). The qPCR results showed NGF were up-regulated (fold change 3.2 and 8.1) in IL-1 β inflamed after 7 days.

Fig. 1. **A.** Percentage ADSCs metabolic activity alamarBlue[®] test shows over 90% and 73% viability in presence of 100 μ L and 200 μ L hydrogels respectively, after 24, 48 and 72 hours in cultures. **B.** NP cells metabolic activity in presence of HA hydrogels shows 100% and 91% viability for 100 μ L and 200 μ L hydrogels. **C.** Immunoreactivity of inflammatory receptor IL1-R1 and MyD88 as observed by fluorescent microscopy for day 3. Inflammatory receptor IL-1R1 and complex MyD88 showed decrease fluorescent intensity after treating with 100 μ L HA hydrogels compared to IL-1 β control group.

CONCLUSION

Crosslinked-HA hydrogels show therapeutic effect by reducing inflammatory receptor and neurotrophins expression in an inflamed *in vitro* model of Nucleus Pulposus cells.

Osteogenic Activity of Adipose Derived Stem Cells on Micropatterned Collagen-Fibroin Blend Films

E. Sayin^{1,2,3}, E. T. Baran³, V. Hasirci^{1,2,3*}

Departments of ¹Biotechnology, ²Biological Sciences, METU, Turkey

³BIOMATEN, Center of Excellence in Biomaterials and Tissue Engineering, METU, Turkey, esayin@metu.edu.tr

INTRODUCTION

Scaffold microtopography and surface chemistry can help differentiate stem cells into a specific tissue type¹. Adipose derived stem cells (ADSCs) can be collected from patients easily with fast recovery after operation unlike bone marrow mesenchymal stem cell harvest². In this study, collagen-fibroin composite biomaterials were patterned with micropillars and grooves to investigate the level, osteogenic differentiation of ADSC for bone tissue engineering applications.

EXPERIMENTAL METHODS

Micropatterned films were produced by solvent casting collagen-fibroin solution on poly(dimethylsiloxane) (PDMS) templates. After carbodiimide and N-hydroxysuccinimide crosslinking, ADSCs were seeded on the films and cultured for 7 days without osteogenic medium (OM) and which was then changed to OM. Alamar blue assay (n=3-5) was used for cell proliferation and ALP assay (n=3-5) was carried out for osteogenic activity of ADSC. Statistical analysis was performed by using one way ANOVA with Tukey test ($p < 0.05$ shows statistically significant pairs).

RESULTS AND DISCUSSION

Cell proliferation results indicated that ADSC can proliferate on micropillars (MP) more vigorously than on unpatterned surfaces or TCPS control (Figure 1a). The lowest proliferation rate was detected on microchannel (MC) patterned film. After freeze drying films were brittle unlike their wet state (Figure b-c).

Fig. 1. ADSC proliferation level on Days (a) 1, 7, 14, 21 and 28. MicroCT images on Day 28: ADSC seeded (b) MC, and (c) MP patterned composite films (between points: 500 μ m, pixel size: 2 μ m).

However, slow cell proliferation and high ALP level, on MC films indicated higher osteogenic activity on this particular surface (Figure 2).

Detection of deposited collagen type I and calcium on the blend films were performed by collagen type I immunostaining (Figures 3a-c) and Alizarin red S (Figures 3d-f) staining, respectively, showed the osteogenic differentiation of ADSCs by osteogenic medium on both pattern types.

After staining of the cytoskeleton and image analysis of MC patterned composite films higher cell alignment and more elongated cell features were observed suggesting that the patterns which induce higher cell aspect ratio might also be responsible for the higher osteogenic activity of ADSCs.

Fig. 2. ALP levels per cell were determined on Days 7, 14, 21 and 28. Statistical differences between TCPS and other groups were analyzed (* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$; *: TCPS vs unpatterned, MC and MP; #: unpatterned vs MC and MP; +: MC vs MP).

Fig. 3. Confocal laser scanning microscopy images of collagen type I immunostaining on Day 28 on (a) unpatterned, (b) MC, (c) MP patterned composite films (x10). Phase contrast microscopy images of Alizarin red S staining on (d) unpatterned, (e) MC, (f) MP patterned composite films (x20).

CONCLUSION

Collagen-fibroin composite films presented higher ADSC proliferation rates than TCPS and pillar patterns. Channel type patterns did not yield a high proliferation rate but they enhanced expression of the osteogenic differentiation marker. Secretion of collagen type I and deposition of calcium indicated ADSC osteogenic activity on all surface types. In conclusion, patterned collagen-fibroin blends appear to be suitable for ADSC growth and differentiation.

Regulation of mesenchymal stem cell differentiation by changing the molecular structure of supramolecular surfaces

Ji-Hun Seo^{1*}, Sachiro Kakinoki², Tetsuji Yamaoka², and Nobuhiko Yui¹

¹Institute of Biomaterials and Bioengineering, Tokyo Medical and Dental University, Japan, seo.org@tmd.ac.jp

²National Cerebral and Cardiovascular Center Research Institute, Japan

INTRODUCTION

Extensive research has been conducted on the regulation of mesenchymal stem cell (MSC) differentiation by altering physicochemical factors, including stiffness, microtopography, and three-dimensional mechanical strength. However, the importance of the surface mobility of polymer surfaces in a hydrated state, one of the characteristic properties of polymer surfaces, in controlling stem cell differentiation is not yet gaining much attention. A simple surface treatment capable of regulating stem cell lineages by changing the molecular mobility has great potential for many biomedical applications because it provides a simple and convenient method of directing stem cell lineage on various material surfaces without changing the bulk properties.

In the present study, we report the feasibility of directing stem cell differentiation on supramolecular surfaces that are prepared with a simple surface treatment. The underlying concept that we applied is modulating the morphology of adhering stem cells using a wide range of molecular mobility of polymer surfaces in a hydrated state. Because morphologies of adhering stem cells have been known as an important factor in determining stem cell differentiation, we hypothesized that a simply deposited supramolecular surfaces capable of changing the adhesion morphology of cells could induce different stem cell differentiation.

Polyrotaxane (PRX) is a supermolecule that contains molecularly movable host molecules [e.g., α -cyclodextrin (α -CD)] threaded on a linear guest molecule [e.g., poly(ethylene glycol) (PEG)]. By adopting this threaded macromolecular structure of polyrotaxanes, we developed polymer surfaces with a wide range of surface mobility by simple deposition method,^{1,2} and the effect of surface mobility on the differentiation of MSC was investigated.

EXPERIMENTAL METHODS

ABA-type triblock copolymers containing threaded PRX segment as B unit and surface anchoring group (A unit) were synthesized by reversible addition-fragmentation chain-transfer (RAFT) polymerization after synthesizing pseudo-PRX macro-chain-transfer agent (CTA). The surface anchoring group (A) is a random copolymer segment composed of 2-methacryloyloxyethyl phosphorylcholine (MPC) and n-butyl methacrylate (BMA) (PMB). PRX block copolymer with two different number of threaded α -CD was synthesized (PRX-A: 12threaded α -CD, PRX-B: 112 threaded α -CD) to modulate the surface mobility of polymer surface. As a non-PRX control sample, a methacrylate random copolymer containing similar chemical component with PRX block copolymer was further synthesized. The surface molecular mobility of the cast polymer was analyzed by means of quartz crystal microbalance-dissipation (QCM-D) equipment,

and MSC adhesion and differentiation was analyzed on each polymer surface.

RESULTS AND DISCUSSION

Surface molecular mobility of PRX-A, which has a smaller number of threaded α -CD, showed the highest value among the prepared polymer surfaces. In contrast, PRX-B surface, which has a larger number of threaded α -CD, showed the moderate value of surface molecular mobility. This is possibly due to the increased molecular rigidity or decreased mobility of the polymer surfaces induced by different number of threaded α -CD. The molecular mobility of the control random copolymer surface showed the lowest value among the polymer surfaces. This indicates that the PRX molecular platform is useful to prepare highly dynamic polymer surface, and the degree of molecular mobility could be easily modulated by simply changing the number of threaded α -CD.

MSCs adhering on the polymer surface with higher molecular mobility showed the narrow and protruded morphology. This resulted in the low expression value of Rho-related protein kinase (ROCK) activity, which is cytoskeletal signalling element related with the MSC differentiation, on the dynamic PRX surface (Fig.1). This indicates that the cytoskeletal signalling element is greatly affected by the surface mobility of the polymer surface. As a result, MSCs on the dynamic PRX surface were easily differentiated into adipogenic cells while those on the surface with lower molecular mobility were easily differentiated into osteogenic cells.

Fig.1 Relative ROCK activity of adhering MSC and the differentiation level of adhering MSCs

CONCLUSION

Different tendency of MSC differentiation was successfully induced by changing the surface mobility of simply deposited polymer surfaces. By adopting the threaded macromolecular platforms, we could demonstrate the importance of molecular mobility of polymer surface for regulating MSCs differentiation.

INTRODUCTION

Application of tissue engineering in site of bone defects has used scaffolds with respect to bone analogue concept, using inorganic and organic composites, and have shown cell growth^{1,2}. Preliminary studies have prepared hydroxyapatite and alginate *Sargassum crassifolium* (*S.crassifolium*) composite scaffolds with pore size up to 250 µm in diameter³. The hydroxyapatite powder was synthesized with low heat treatment temperature to obtain amorphous material^{4,5}. The alginate *S.crassifolium* powder were extracted from the macroalgae of Indonesia seas and has shown as typical alginates^{6,7}. The ability of cells to attach to the surface of the materials is important for further cellular process. The suitability for cell culture of the scaffold, however, has not been studied. The present study, therefore, aimed to observe cell viability and cell attachment in the hydroxyapatite/alginate *S.crassifolium* composite scaffolds after seeded with stem cells.

EXPERIMENTAL METHODS

Hydroxyapatite/alginate *S.crassifolium* composite scaffold samples were prepared following previous studies^{1,3}. For a control, scaffold samples from commercially available hydroxyapatite and alginate (Sigma-Aldrich, USA), were also prepared. Mesenchymal stem cells used in the present study was isolated from the medullary bone of human femur. Viability was initiated with cell culture for 24h in the presence of sterilized scaffold samples⁸. Cell viability test was conducted with extract medium concentrations ranging from 100% to 1%. The extract medium was removed and osteogenic medium with MTT assay was then added to the cultures. Incubation was conducted for 3h. Absorbance was measured in a spectrophotometer at a wavelength of 540nm. For cell attachment, sterilized scaffold samples were placed in a 24-well plate and suspended in osteogenic medium. Mesenchymal stem cells were then seeded over the whole upper surface of the sterilized scaffold samples. After 6 weeks of incubation, scaffold samples were sectioned in many planes and were then observed using a scanning electron microscope.

RESULTS AND DISCUSSION

Results of MTT assay test showed that the hydroxyapatite/alginate *S.crassifolium* scaffold samples with extract concentrations of 100% to 1% showed cell viability of 35.9% to 101.5%, in comparison to the control, i.e. 74.8% to 127%. After six weeks of cell seeding, majority of the cells were seen in the sterilized

scaffold samples, as well as, in the control. The cells were rounded morphology showing organelles appeared with extension to cell surfaces. Some cells appeared in cluster, while others were randomly solitary. Most cells were spread evenly and were well attached to the exterior and internal part of the interconnected pore walls of the scaffold samples. This cell attachment in the structure of the hydroxyapatite/alginate *S.crassifolium* composite scaffolds indicated that the materials used to prepare the scaffold did not have any negative effect on the cells.

CONCLUSION

The study showed that the hydroxyapatite/alginate *S.crassifolium* composite scaffolds have revealed with excellent cell viability to the mesenchymal stem cells used. The mesenchymal stem cells seeded onto the hydroxyapatite/alginate *S.crassifolium* composite scaffolds have presented the existence of cell attachment inside the scaffolds.

Application of Bone Morphogenetic Protein-6 and Induced Pluripotent Stem Cells in Periodontal Tissue Regeneration

Kuang-Lin Tung¹, Yung-Hsin Cheng², Shih-Hwa Chiou³, Kuang-Dah Yeh^{4*}

¹Institute of Oral Biology, National Yang-Ming University, Taipei, Taiwan

^{4*}Tri-service General Hospital, Taipei, Taiwan, amytung16@gmail.com

INTRODUCTION

Periodontal disease can result in alveolar bone loss or even tooth loss, severely impacting on the aesthetics and masticatory ability of the affected patients. Bone morphogenetic proteins (BMPs) are powerful inducers of osteogenic activity during the embryologic bone formation phase. BMP-6 has been shown to have the ability to induce periodontal tissue regeneration, including the alveolar bone, periodontal ligament, and cementum.¹ Induced pluripotent stem cells (iPSCs) has been shown to create increased alveolar bone and cementum as well as periodontal ligament formation in a periodontal defect animal model. However, the effect of BMP-6 on the iPSCs ability to regenerate periodontal tissue has not been studied. The purpose of our research was to investigate the periodontal tissue (periodontal ligament cells, cementum, and alveolar bone) regeneration ability of iPSCs under the influence of BMP-6.

EXPERIMENTAL METHODS

In this study, a self-developed injectable thermosensitive chitosan/gelatin/glycerol phosphate (C/G/GP) hydrogel was used.² The cytotoxicity of the C/G/GP hydrogel was evaluated using crystal violet assay and lactate dehydrogenase assay. The *in vitro* release study of DEX-containing (2.5 mg/ml, 5 mg/ml, and 10 mg/ml) hydrogel was investigated using UV-spectroscopy. We added BMP-6 (0.1 ng/ml and 1 ng/ml) to the osteogenic medium in order to investigate the differentiation ability of iPSCs, then the mineralization ability was studied using Alizarin red S staining. For *in vivo* study, the BMP-6-containing hydrogel cultured with or without iPSCs was used as the periodontal defect substitute. The new bone formation at the periodontal defect region of rats was determined using micro-computed tomography (micro-CT); the histomorphology of defect region was investigated using the hematoxylin and eosin (H & E) staining.

RESULTS AND DISCUSSION

Compared with the control group (extract-free medium), the experimental group (extract of hydrogel) was non-

cytotoxic to iPSCs (Fig. 1 (a)), the cumulative releasing test shows that the DEX in hydrogel could sustain releasing (Fig. 1 (b)). The iPSCs-derived osteoblasts mineralization forming ability is shown in Fig. 1 (c), indicating that the 1 ng/ml BMP-6 group had the best mineralization ability among the test groups. The H & E staining analysis results shows that the periodontal ligament like-cells could be detected

CONCLUSION

The C/G/GP hydrogel has no cytotoxicity and is suitable for sustained delivery of DEX. The presence of BMP-6 enhances the mineralization forming ability of iPSCs. Compared with the control group (hydrogel only), the micro-CT and H & E staining analysis results indicate that the presence of BMP-6, cultured with or without iPSCs, enhances the new bone formation and the periodontal ligament-like cells formation at the periodontal defect region, respectively. We conclude that combining BMP-6 and iPSCs provides a potential method for periodontal tissue regeneration.

Dynamic Polysaccharide-based Carrier Systems for the Delivery of Biotherapeutics

Denise N. Bamberger¹ and Peter R. Wich^{1*}

¹ *Institut für Pharmazie und Biochemie, Johannes Gutenberg-Universität Mainz, Germany*
wich@uni-mainz.de

Polymer-based drug, vaccine and gene delivery systems can be easily modified and are particularly attractive because of their ability to perform several critical functions simultaneously. These include delivering therapeutic or other bioactive agents to a specific site via a targeting mechanism, increasing the circulation times of drugs in the body, protecting drugs from degradation, or increasing the bioavailability of poorly soluble drugs.

Recently, a new class of modular and acid-degradable, polymeric particles using acetal-modified dextran (Ac-DEX) was developed.¹ This biocompatible material can be formulated into particles using a variety of common emulsion-based techniques enabling control over both size and morphology. Due to their pH sensitivity, Ac-DEX particles can selectively and rapidly release their encapsulated payload under mildly acidic conditions including those found in sites of inflammation, tumor tissue, or endocytic vesicles. Upon hydrolytic degradation, Ac-DEX reverts back to FDA-approved dextran

without the generation of acidic by-products that could damage the encapsulated payload or lead to inflammation, as has been observed with some other commonly used polymer systems. In addition, Ac-DEX particle degradation rate can be easily tuned within the time scale of relevant cellular processes. This release tunability combined with their low-toxicity and payload versatility make Ac-DEX particles an ideal platform for a wide range of biotherapeutic delivery applications including immunotherapy² and gene delivery.³

Amphiphilic Graft Polyester-g-polysaccharide Copolymers for Sustained Drug Release

L. Martellotto¹, J. Buisson¹, H. Van Den Berghe^{1*}, J. Coudane¹

¹Artificial Biopolymers Department, Max Mousseron Institute of Biomolecules, University Montpellier 1, France, helene.van-den-berghe@univ-montp1.fr

INTRODUCTION

Biocompatible amphiphilic copolymers with well-defined architectures are one of the challenging areas in polymer science because they are able to form nanostructures in aqueous medium with potential as drug delivery systems^{1,2}. In this field, aliphatic polyesters, such as poly(ϵ -caprolactone) (PCL), are interesting hydrophobic candidates as a result of their biodegradability, biocompatibility and FDA approval. Moreover, polysaccharides, such as dextran, are hydrophilic polymers of choice because they are renewable, biocompatible and protein repellent that confer stealth to nano-objects³. However most of the graft copolymers described in the literature and prepared from these types of polymers was constituted of a hydrophilic backbone and hydrophobic side chains due to the lack of functionalities along the hydrophobic polyester chains. Few years ago, our team described a general synthetic route, *via* anionic activation, allowing functionalising polyesters along their backbone⁴. This new strategy gave access to numerous new functional polymeric structures such as propargylated PCL⁵. The purpose of this work is first to functionalise and make “clickable” dextran in order to covalently graft it onto propargylated PCL. Nanocarrier structures were built up with this graft architecture, to be used for drug encapsulation (anti-cancer agents, antibiotics, growth factors,...) and sustained release of these drugs.

EXPERIMENTAL METHODS

Synthesis. “clickable” dextran. Dextran was chemically modified to its reductive hemiacetal chain extremity by coupling bromopropylamine or cysteamine *via* reductive amination. Typically bromopropyl-dextran was then transformed in azidopropyl-dextran by reaction with sodium azide. *Amphiphilic PCL-g-dextran copolymer.* “Clickable” dextran was covalently grafted to propargylated PCL backbone by a “click” reaction.

Preparation of nano-objects. Nanoparticles or polymeric micelles were prepared by typical nanoprecipitation technique.

RESULTS AND DISCUSSION

The synthesis of “clickable” dextran was realised *via* a reductive amination pathway. Then the functionalized dextran was covalently grafted to propargylated PCL backbone (Figure 1) according to a click reaction, under mild conditions to preserve the copolymer from degradation.

The grafting and the resulting copolymer structure were demonstrated by DOSY analysis and Size Exclusion Chromatography measurements. The percentage of hydrophilic dextran chains grafted to a hydrophobic PCL backbone was determined by ¹H-Nuclear Magnetic Resonance.

Figure 1: Synthesis of amphiphilic graft PLC-g-dextran copolymer

Nanoprecipitation route provided nano-objects (micelles or nanoparticles) in aqueous medium and characterised by quasi-elastic light scattering measurements. The resulting new nanostructures were compared to PCL nano-objects in terms of drug encapsulation load capacity and kinetic of *in vitro* drug delivery. These preliminary assays were realised with a hydrophobic drug model.

CONCLUSION

Well-defined functional PCL and “clickable” dextran were synthesised and used as building blocks for the synthesis of biocompatible amphiphilic PCL-g-dextran copolymers. Nanostructures of this new copolymer architecture were successfully prepared by nanoprecipitation and well-characterised. The versatility of the strategy developed herein paves the way for preparation of various nanocarriers, modulating the drug delivery kinetic according to the length of the native polymeric chains. Next step will consist in the covalent attachment of sugar residues (mannose, galactose) as targeting agents to the surface of micelles for site-specific drug delivery applications, for example the targeting of cancer cells.

INTRODUCTION

Micro and nano systems gained significant attractions in medical applications especially as diagnostic or therapy devices. One problem is the long term safety of these systems if they are not degradable or their degradation products are not biocompatible. One other problem is the laborious and expensive production of these systems (1-4). In this study some micro and nano systems prepared from various polymers or activated with certain polymers as drug carriers were examined. Some systems were converted to composite forms with addition of hydroxyapatite (HAp) or tricalcium phosphate (TCP) particles and added into scaffolds to use them for bone tissue engineering applications. Chemical structures, physical forms, mechanical and thermal properties and their effects on cells or tissue were examined.

EXPERIMENTAL METHODS

Various micro or nano particles were prepared from gelatin (G), chitosan (CH), polyvinylpyrrolidone (PVP), polyethyleneoxide (PEG), poly(lactic acid-co-glycolic acid) (PLGA) and poly(hydroxybutyrate-co-hydroxy valerate) (PHBV) as polymeric systems and some of them were blended with other polymers or inorganic apatite crystals. Chemotherapeutic agents as colchicine, methotrexate and 5-fluorouracil were loaded into G and CH micro particles; bone morphogenetic proteins were loaded into PLGA and PHBV nano capsules; gentamicin as an antibiotic and epidermal growth factor (EGF) as an bioactive agent were loaded in to gelatin or gelatin-TCP composite micro carriers. Release kinetics of each system was studied in vitro. Meanwhile, the effects of scaffolds containing these micro or nano systems on cells were examined in vitro and in vivo conditions implanting scaffolds in bone defects of rabbits (Figure 1).

Figure 1. Surgical operation of scaffolds containing gentamicin loaded micro carriers

RESULTS AND DISCUSSION

Release of chemotherapeutic agents from gelatin microspheres were fast because of fast degradation of the particles. Chitosan micro particles were quite stable in buffer media and the release occurred only in the presence of enzyme lysozyme.

Microparticles containing colchicine, methotrexate and 5-fluorouracil all showed significant effect on breast cells. Microparticles containing antimicrobial agents were effective to *E.coli*; and nanoparticles having growth factors showed fast and proper tissue healing. Meanwhile, PCL scaffolds containing microspheres of β -TCP/G loaded with gentamicin caused an increase in bone regeneration without any adverse effect. The cells were able to attach and proliferate on these composite scaffolds. Histological analyses demonstrated enhanced tissue integration in the composite scaffolds.

Figure 2. Results of histological scoring at 8 weeks post implantation: Scores for (A) the hard tissue response at the bone-scaffold interface; (B) the hard tissue response within scaffold; (C) bone formation within defect (Error bars represent SD for n=6; * p<0.05).

CONCLUSION

Micro nano carriers as well as scaffolds loaded with these carriers are effective tools for drug delivery and tissue engineering applications.

Fibrin-based Microsphere Reservoirs for Delivery of Neurotrophic Factors

Juhi Samal¹, Eilis Dowd² and Abhay Pandit^{1*}

¹Network of Excellence for Functional Biomaterials,

²Pharmacology and Therapeutics, National University of Ireland, Galway, juhisamal@gmail.com

INTRODUCTION

Neurotrophic factors promote the differentiation, growth and phenotypic maintenance of neurons and act as a potential means of modifying neuronal dysfunction in neurodegenerative disorders like Parkinson's disease. However, their therapeutic application is limited by their short half life *in vivo*. This calls for a biomaterial based intervention which protects the neurotrophins until they are delivered to the desired site and allows a controlled release to achieve therapeutic effects. Fibrin as a biomaterial offers the advantage of being an autologous substrate where the rate of polymerization and degradation can be well controlled. The hypothesis of this study is to establish that template charge manipulation can lead to fabrication of hollow fibrin microspheres as a reservoir for controlled delivery of the neurotrophins. Specific objectives were to fabricate and characterize the fibrin based reservoir system, evaluate the loading and release profiles, investigate interaction with cells and impact of neurotrophin encapsulation on its bioactivity.

EXPERIMENTAL METHODS

Hollow fibrin microspheres were fabricated by template charge manipulation method¹. The hollow microspheres were characterized by Scanning Electron (SEM), Transmission Electron Microscopy (TEM) and zeta potential analysis. Protein loading and release from the microspheres was demonstrated using NGF as a model neurotrophin. Loading efficiency and release profiles under different conditions were determined using ELISA. Fluorescent labelling of NGF and microspheres was done to facilitate the detection of loading using fluorescence microscopy. Impact of different concentrations of fibrin microspheres on metabolic activity and viability of rat mesenchymal stem cells (rMSCs) and PC-12 cells was shown using alamar BlueTM and live/dead assay. Bioactivity of released NGF was demonstrated by neuronal outgrowth assay in PC-12 cells which was quantified using β III tubulin immunostaining. Statistical analysis was performed using two tailed Student t-test ($p < 0.05$, $n = 3$).

RESULTS AND DISCUSSION

Manipulation of template charge followed by core dissolution resulted in the formation of hollow fibrin microspheres which were stable across a wide range of working conditions. Also the microspheres showed high loading efficiency (>80%) for all sizes of microspheres used (Fig. 1A). NGF-microsphere interaction was also shown using fluorescent labelling of growth factor and microspheres (Fig. 2). The results from alamarBlueTM and live/dead assay showed that there was no adverse impact of fibrin microspheres on cell viability even at higher concentrations (Fig. 3A,B).

Fig.1. Loading efficiency of fibrin hollow microspheres for (A) different sizes of microspheres and (B) different doses of NGF (data represents mean \pm SD, $n = 3$) (C) Fibrin hollow microspheres after core dissolution using tetrahydrofuran (SEM)

Fig.2. Fluorescence images for loading of NGF into the microspheres (green, fibrin spheres; red, NGF; yellow, colocalization of NGF and fibrin)

Fig.3 Cellular metabolic activity of (A) rMSCs and (B) PC-12 cells compared with PBS-treated cell (alamarBlueTM assay)

Neurite outgrowth assay and quantification using β III tubulin immunostaining showed that neurotrophin encapsulation into the microspheres did not alter its bioactivity.

CONCLUSION

Fibrin hollow microspheres act as a delivery platform for neurotrophic factors showing high loading efficiency, maintaining their bioactive form and no adverse interactions with cells. Also the absence of any chemical cross-linkers in this system offers an advantage over other biomaterial systems used in similar applications.

INTRODUCTION

Repair of bone defects arising from disease or traumatic injury in the oral and maxillofacial complex is a major challenge for clinicians restoring form and function in this emotionally sensitive region. Therefore, therapeutic strategies are continually being developed to enhance bone regeneration and guide bone growth. Periodontitis is an inflammatory disease affecting tooth supporting structures and may result in loss of the supporting alveolar bone necessary to maintain teeth in the jaws. Periodontitis has been reported to affect 10-15% of the adult population and this may increase to affect 85% of adults over 70 years of age. Management of tooth loss may require the placement of a dental bridge and/or a dental implant. To further complicate clinical management of tooth loss, dental implants may be compromised by peri-implantitis, an inflammatory response resulting in bone loss around the implant. The clinical success for a dental implant is compromised by poor osseointegration with alveolar bone. However, osseointegration and management of peri-implantitis may be improved by optimising the regenerative potential of adjacent bone. Currently, regeneration of the periodontium is managed by a number of approaches. These include the use of autografts, allografts, cell occlusive barrier membranes, and biodegradable hydrogels. These materials are typically used in association with bioactive molecules to assist periodontal regeneration. In the current study, we have developed an injectable mixed macromonomer system able to be polymerized *in situ* and is biodegradable, to promote regeneration of the periodontium¹ and do not require a secondary surgical intervention.

EXPERIMENTAL METHODS

A water-soluble macromonomer based on octavinyl silsesquioxane has been synthesized with vinyl-terminated PEG-400 in each of the eight arms to promote water solubility (**POSSPEGA**). The methods for synthesis of this macromonomer and the copolymers prepared from it are outlined in Scheme 1 below. The equilibrium swelling ratios, degradation and hydrogel morphology as a function of the copolymer composition have been evaluated. Cytocompatibility for proliferation, viability, immunohistochemistry and attachment of periodontal fibroblasts was conducted using freshly prepared and degraded hydrogels.

RESULTS AND DISCUSSION

The **POSSPEGA** was characterized by NMR and ATR-FTIR analysis and its solution properties were examined.¹ In water it exhibits an LCST with a cloud point at 23 °C. TEM analysis showed that **POSSPEGA** forms spherical aggregates with a diameter of 22 ± 4 nm in water.¹

Scheme 1: Synthesis and polymerization of POSS based hydrogels

The **POSSPEGA** copolymers formed with diacrylated PLA-PEG-PLA, **PEGL₅DA**, show greater extents of swelling in water than in PBS at pH 7.4 because of salting out of the PEG chain segments. The hydrogels have a porous morphology with the size of the pores dependent on the comonomer composition.² In PBS, the hydrogels undergo extensive hydrolysis over time, and the rate of mass loss is strongly dependent on the initial amount of the incorporated lactide. A cytocompatibility study using periodontal fibroblasts, isolated from a female Lewis rats, showed no effect of the hydrogels on fibroblast proliferation, viability and immunoexpression of bFGF and vimentin, either initially and after one PLA hydrolysis half-life, but a minor inhibition of attachment was observed initially.

Fig 1: Confocal microscopy images of periodontal fibroblasts on **POSS** hydrogel (scale bar = 20 μm) and Cryogenic SEM micrographs of **POSS** hydrogel (scale bars = 10 μm).

CONCLUSION

The hydrogel was shown not to inhibit the fibroblast proliferation rate, or the fibroblast attachment after hydrolysis had proceeded to some extent (see Fig 1).¹ An *in vivo* study of the hydrogels has been successful in drug delivery during the repair of artificial defects in the mandibles of rats.

Effects of Calcium Phosphate and an adhesion promoting monomer on Strength, Degree of Conversion and Adhesion of Dental Composites

Anas Aljabo¹ and Anne Young^{2*}

¹⁻² Biomaterials and Tissue Engineering/ Eastman Dental Institute, University College London, UK.
anas.aljabo.10@ucl.ac.uk

INTRODUCTION

Dental caries is one of the most common preventable diseases. It is associated with bacteria that, through acid formation, cause demineralisation of tooth structure, oral pain, and ultimately tooth loss. The acid is produced through bacterial fermentation of food. This disease is chronic but can be treated and potentially reversed at early stages (1, 2).

Once the disease has progressed through to the dentine treatment involves removal of diseased tissue and replacement with a filling. With the imminent worldwide ban on amalgam fillings arising from the Minamata agreement, alternative white dental composites and to a lesser extent resin modified glass ionomer cements will become the main tooth restorative materials. Composite failure rates, however, can be three times those of amalgam. Typically, 80% of composite restoration replacement is due to failure of the adhesive used to bond the composite to the tooth. The bond fails because during cure the composite shrinks. This then allows bacteria to penetrate (3).

The aim of this study is to develop a “smart” dental composite material that enables greater treatment rather than complete removal and filling of all caries affected tooth structure. Unlike current dental composite fillings, the new material should preferably bond to dentine without additional adhesive use. The following will assess if this can be achieved through addition of an adhesive monomer (4 Meta) and reactive mono and tri calcium phosphates (CaP).

This CaP mixture is known to promote water sorption induced swelling to compensate shrinkage and release of antibacterial chlorhexidine (CHX) (3). It can additionally promote hydroxyapatite precipitation from simulated dentinal fluid which should aid dentine repair. The aim of this study, however, is to assess what levels of CaP can be added without excessive loss of rapid controllable light activated setting or strength.

EXPERIMENTAL METHODS

Light curable dental monomers were prepared by mixing urethane dimethacrylate : triethylene glycol dimethacrylate : hydroxyethyl methacrylate : camphorquinone : dimethylparatoluidine : 4 Meta in the weight ratio 66:22:5:1:1:5. This was combined with silane – treated dental glass particles containing fibers (20wt%), CaP (0, 10, 20 or 40wt%) and CHX (10 wt%) at a powder to liquid ratio of 4.

The biaxial flexural strength of composite discs (10 mm diameter, 1 mm thick) was determined after 24 hours immersion in water. Monomer conversion (MC) (at 1 and 4 mm thickness) was checked via FTIR after 20s light cure. Depth of cure (DOC) was also obtained by condensing three specimens of each material type into metal molds (4mm diameter and 6mm deep), curing from one side for 20s and scraping away soft material

using a plastic spatula. The length of the remaining specimen (DOC) was measured. According to ISO 4049 this should be >3.0 mm. Shear bond strength (SBS) to ivory dentine was additionally determined. For comparison, a conventional commercial composite Z250 and two newer self-adhering composites (Vertise Flow (VF) and Fusio Liquid Dentine (FLD)) were utilized.

RESULTS AND DISCUSSION

Flexural strengths of experimental formulations without calcium phosphate reactive fillers were comparable with that of the commercial composite Z250. With raising CaP, strength declined but still remained higher than that of the commercial resin modified glass ionomer (RMGIC), Fuji II LC (84MPa). All composites except 40% CaP had a DOC above the required 3.0 mm minimum (Table 1). MC measurements, however, show significantly reduced monomer curing at 4 mm depth compared with 1 mm for all materials except the experimental control composite. These studies highlight that materials may appear hard with < 50% conversion. This could enable significant release of uncured monomer is possible and that additional studies to ISO tests are important. Higher levels of CaP enabled shear bond strengths comparable with self-adhering composites but below that of Z250 with ibond use.

CaP wt%	Strength (MPa)	DOC (mm)	MC (%)		SBS* (MPa)
			1 mm	4 mm	
0	175	4.2	70	68	13
10	160	3.6	71	50	15
20	149	3.0	70	40	26
40	137	2.6	70	37	33
Z250	180	5.0	50	35	40*
VF	148	4.6	65	39	32
FLD	150	5.0	66	38	35

Table 1. Comparison of experimental and commercial composite properties. * SBS was determined without use of adhesive except in the case of Z250

CONCLUSION

Monomer conversion at 4mm decreased with reactive filler addition due to decline in translucency. Although of reduced strength and monomer conversion the above composites with added CaP have improved bonding that could make placement easier, prevent bacterial microleakage and enhance restoration longevity.

furqan.ali.shah@biomaterials.gu.se

INTRODUCTION

Hierarchical surface treatments are often considered¹ for mimicking the different length scales of the constituent structures in bone, in order to improve biomechanical fixation of osseointegrated implants. Controlled micro- and nanoscale surface modification of cp-Ti surfaces by laser ablation has been shown to be favourable in this regard.² And indeed, nanoscale surface features modulate cellular behavior and differentiation.³ This study was aimed at resolving the fine structure of bone adjacent to osseointegrated, functionally loaded, nano-textured implants in human.

EXPERIMENTAL METHODS

Partly laser-modified (*Fig. 1a-c*) implants (BioHelix™; Brånemark Integration AB, Mölndal, Sweden) were retrieved after 47 months of functional loading, from the maxilla of a 66-year old Caucasian female, for reasons other than biological failure. Histomorphometry was performed by light microscopy (LM) and backscattered-scanning electron microscopy (BSE-SEM). Transmission electron microscopy (TEM) and high angle annular dark field-scanning TEM (HAADF-STEM) were used for ultrastructural analysis. Micro-computed tomography (μ CT) was employed to evaluate tissue architecture in 3D.

RESULTS AND DISCUSSION

On the histological level, well-organized osteonal lamellar bone was found within the implant threads. High amounts of mineralized bone (bone area >80%, bone-implant contact >80%) were observed within the threads by LM, BSE-SEM (*Fig. 1f*) and μ CT. HAADF-STEM showed a characteristic cross-striated pattern of collagen approximately perpendicular to and reaching up to 100 nm from the surface (*Fig. 1d*), closely following the surface micro-contour consistently up to 2 μ m away, suggesting topography-related organization of collagen. At greater distances, collagen fibrils organized into concentric bundles (ϕ =1–3 μ m). Selected area electron diffraction (SAED) revealed preferential orientation of apatite crystallographic *c*-axis, i.e. (002) or (004) reflections, aligned along the collagen fibril direction (*Fig. 1e*). Almost no (002) and (004) reflections were observed for transversally sectioned collagen fibrils (ϕ =50–70 nm). Individual fibrils were separated by multiple extrafibrillar mineral platelets 59.01 \pm 9.11 nm (length) and 5.05 \pm 0.61 nm (thickness). STEM-EDX showed at. % C/Ca=3.33 \pm 0.95 for these collagen fibrils. The mineral platelets showed at. % C/Ca=1.33 \pm 0.50 and at. % Ca/P=1.33 \pm 0.15 indicative of bone-apatite. These ultrastructural observations show that bone interfacing the implant surface is highly organized, exhibiting directional and size organization

similar to mature bone tissue.⁴ STEM-EDX also revealed an overlap of Ti, O, Ca and P signals at the interface zone, indicating gradual intermixing of bone-apatite with the TiO₂ layer. This overlapped zone has previously been resolved by electron tomography⁵ as bone ingrowth into nanoscale irregularities of the surface. Multi-scale analysis of retrieved, functionally loaded human implants is critical to extend pre-clinical understanding of osseointegration.

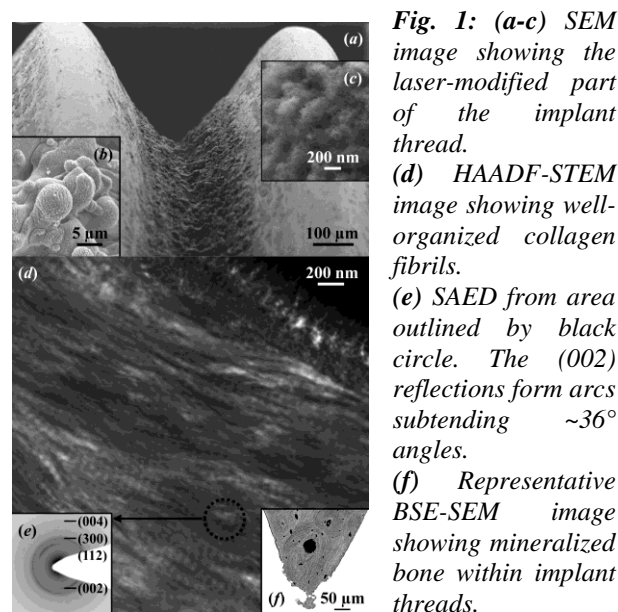

Fig. 1: (a-c) SEM image showing the laser-modified part of the implant thread. (d) HAADF-STEM image showing well-organized collagen fibrils. (e) SAED from area outlined by black circle. The (002) reflections form arcs subtending ~36° angles. (f) Representative BSE-SEM image showing mineralized bone within implant threads.

CONCLUSION

The present study demonstrates, for the first time in human, that nano-textured titanium implants promote hierarchical organization of bone, resulting in a functionally graded interface and direct bonding to the nanoscale surface TiO₂ layer.

INTRODUCTION

Nowadays the bone or tissue reconstruction is a clinical tool, particularly in dental surgery¹. The challenge is to promote the regeneration of specific cells and to prevent ingrowth of soft tissues. This goal can be achieved with non biodegradable² or degradable membranes made of polyester³ or collagen⁴. More than 20 products are available for this specific purpose. The evaluation of the clinical benefits of several commercial membranes is widely described in the literature. However no data are available concerning the physico-chemical and mechanical properties of this kind of biomedical material.

EXPERIMENTAL METHODS

In this study, seven commercially available membranes from different materials were analyzed on both faces: a synthetic non biodegradable membrane (PTFE), three synthetic biodegradable products (polyester) and three samples made of collagen.

The samples were first analyzed as received. Since most of the membranes are moistened before implantation, analyses were also performed with the samples soaked in an aqueous solution, except in the case of a contrary mention by the manufacturer.

Their morphology was investigated on both faces by scanning electron microscopy. The chemical composition and the hydrophilicity were evaluated before and after the water treatment and drying at room temperature, by X-ray Photoelectron Spectroscopy (XPS) and static angle contact measurements. The viscoelastic properties of the membranes were investigated by Dynamic Mechanical Analysis in the shear mode. The ease of handling the moist membranes was also evaluated and correlated with the dynamic mechanical analyses.

RESULTS AND DISCUSSION

Morphology

The biomaterials present various structures depending on the fabrication process: dense, fibrous or alveolar morphologies were found; an homogeneous or bilayer structure was also observed. Three membranes display asymmetrical faces (smooth and rough, respectively). It is well known that not only the chemical surface composition governs the interactions between biomaterial and cells, the surface topography is also a key factor to control the cell activity.

Hydrophilicity

Except for the PTFE membrane and one polyester membrane, the samples are either hydrophilic by nature (those made of collagen), or treated in surface or in bulk in order to improve the wettability and the water uptake.

Surface chemical composition

The elemental and functional composition of the surface layers was investigated by XPS. The detailed analysis of each peak shows the preferential segregation of specific blending components during the manufacturing process or the presence of surfactants, in the case of polyester membranes. Concerning collagen membranes, the drying stage leads to the migration of more hydrophobic species in the upper layers.

Mechanical properties

First, the hydrated samples were subjected to force-displacement experiences at 1 Hz in order to determine the range of the linear viscoelastic region. The relative position of each curve leads to a classification of commercial membranes, based on the rigidity and deformation properties. At small deformations, no dependence in frequency was observed between 0.1 and 100 Hz. The quantification of the pure elastic modulus and the loss factor leads to a better comprehension of the viscoelastic properties in the conditions of use by the periodontist.

CONCLUSION

This study devoted to the characterization of commercial membranes shows a wide variety of biomaterials for Guided Tissue Regeneration in dental surgery, regarding their morphology, surface chemistry or mechanical properties. The PTFE membrane is considered as a good barrier due to the inert nature of this biomaterial but the implant has to be removed. The membranes made of collagen display a good wettability for promotion of tissue integration but their handling strongly depends on the addition of a crosslinker. Although their morphology and wettability have been finely tuned for tissue regeneration, biodegradable polyester membranes are stiffer and less convenient to use, except by addition of a plasticizer.

INTRODUCTION

Cornea, the outer layer of the eye, is the first lens of the eye. It is composed of several distinct layers, amongst which are the corneal epithelium and the corneal stroma. The stroma accounts for around 90 % of the total thickness. It is mainly composed collagen type I^{1,2}. Collagen fibrils are ≈ 20 nm in diameter, regularly spaced and form layers reminiscent of a plywood^{3,4}. In case of corneal diseases leading to a loss of vision, corneal allografting remains the standard procedure. Alternative treatments can make use of synthetic corneal implants. Several research groups across the world are developing collagen-based implants. Our approach makes use of the lyotropic liquid crystal properties of acidic collagen solutions to generate, after neutralization, dense organized and transparent matrices.

EXPERIMENTAL METHODS

3 mg/mL collagen solutions in 500 mM acetic acid were dialyzed to reach 70 mM acetic acid and 1.25 mM hydrochloric acid. Collagen solutions were subsequently concentrated by centrifugation-filtration up to 15, 30, 60, 90 mg/mL. The concentrated solutions were then pressed into cornea-like shape and submitted to ammonia vapour during 17 h hours to increase pH and induce fibrillogenesis of collagen. Transparent dense collagen matrices were collected and stored into water at 4°C until use. Human donor cornea explants were sewed on top of the scaffolds and immersed into cell culture buffer and cultured at 37° (95% air, 5% CO₂) for 15 days. The samples were analyzed for their ultra-structures, mechanical and optical properties and for epithelium development.

RESULTS AND DISCUSSION

Transmission electron microscopy revealed that fibril density and organization increased with concentration. At 90 mg/ml fibrils were organized in layers. Using a custom made device, mechanical tests revealed that the mechanical properties improved with increasing collagen density: the Young modulus was approximately 0.5 kPa for 15 and 30 mg/ml collagen matrices, while for 60 and 90 mg/ml, values reached respectively 1 and 2 kPa. The maximum stress and strain at rupture were similar for low concentrations (20 kPa and 90%) while for 60 and 90 mg/ml, maximum stresses respectively reached 45 kPa and 80 kPa for a similar elongation of 55%. After cell culture, ultra-fine sections of collagen matrices showed that cells had

formed epithelia on the scaffolds. Transparency was measured in the visible range with a spectrophotometer and calculated using the average optical densities measured. At 30 mg/mL the matrices were transparent (e.g. 84%). Transparency increased with time and was very little affected by the epithelium.

Last, experiments in glass microchambers⁵ revealed that liquid crystals organizations obtained with this collagen solution (70 mM acetic acid and 1.25 mM hydrochloric acid) generated cholesteric organization thus different from the plywood organization found in cornea. Therefore other physico-chemical conditions are currently checked for their plywood liquid crystal organizations⁶, their transparency and mechanical properties.

Figure 1 : Cholesteric (left) and plywood (right) organizations

CONCLUSION

Matrices made with collagen at 90 mg/mL (70 mM CH₃COOH and 1.25 mM HCl) present a stabilized cholesteric organization, a Young modulus of 2 kPa and $\approx 80\%$ transparency. They allow development of Human corneal epithelium *in vitro*. New ongoing developments are promising for *in vivo* applications.

INTRODUCTION

Lanthanide ions exhibit unique spectroscopic and luminescent properties that can be applied for bioimaging and bioassay applications. The Ln^{3+} ions adapted easily to any chemical environment, thus it is ready to use as functional centers into a versatile applications. By complexation, we can increase the physico-chemical characteristics. Development of rare earths functionalization for antiamebic activity after exposed to lanthanide complex was investigated. In this study, we synthesized the $[\text{Tb}(\text{NO}_3)_3(\text{OH}_2)_3] \cdot (18\text{C}6)$ to observe biological activity of the Tb complex against *Acanthamoeba* sp. *Acanthamoeba* is a free living amoeba that can caused serious eye disease such as *Acanthamoeba* keratitis. Therefore, in this study the relationships between the dose concentrations of the Ln with the response of the test organisms, *Acanthamoeba* sp. was studied. The mode of *Acanthamoeba*'s cell death was also observed and results obtained indicated the potential of Tb complex as antiamebic agent.

EXPERIMENTAL METHODS

To 1.0 mmol $[\text{Tb}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}]$ and 1 mmol 18C6 is dissolved in CH_3CN . The $[\text{Tb}(\text{NO}_3)_3(\text{OH}_2)_3] \cdot (18\text{C}6)$ complex was isolated after one day with yield 86%. For *Acanthamoeba* cytotoxicity studies, amoeba cells were first seeded in a 96-well microplate at 1×10^5 cells/well and were incubated at 30 °C. After 8 hrs, the medium was removed and replaced with medium containing the Tb complex over a range of doubling dilutions of 0 - 30 $\mu\text{g/mL}$. Triplicate cultures were established for each treatment and incubated for 48 hrs. The Tb's IC_{50} value determination was done by MTT assay. Morphological changes on *Acanthamoeba* cells after treatment with Tb complex at their IC_{50} value was observed under light microscopy followed by assessment for *Acanthamoeba* mode of cell death by application two cationic dyes, Acridine Orange and Propidium Iodide (AO/PI) dyes and viewed under fluorescent microscopy (Leica DMire Microscope, Germany).

RESULTS AND DISCUSSION

The elemental composition and structure properties of terbium trinitrate.trihydrate.18-crown ether-6 complex, $[\text{Tb}(\text{NO}_3)_3(\text{OH}_2)_3] \cdot (18\text{C}6)$, was successfully characterized. The Tb^{3+} ion was coordinated with three of nitrate anions by bidentate mode, three of water molecules, forming a nine-coordination number. The crystal system of terbium complex is orthorhombic with space group of Pnma. This structure is similar with the structure has been previously reported [1]. The IC_{50} value for Tb complex derive from the graph was 7 $\mu\text{g/mL}$. There were significant decreases ($p < 0.05$) in *Acanthamoeba* viability with increasing concentration of Tb complex used (Fig. 1).

Fig 1: Cytotoxicity of $[\text{Tb}(\text{NO}_3)_3(\text{OH}_2)_3] \cdot (18\text{C}6)$ on *Acanthamoeba* sp. after 48 hours treatment, assessed based on percentage of cell viability by MTT assay. The data represent the mean (\pm S.E.M) of three separates experiments. The IC_{50} value obtained was 7 ($\mu\text{g/mL}$) derived from the graph.

Untreated and Tb-treated *Acanthamoeba* were observed under light and fluorescence microscopy demonstrated changes after treatment with Tb complex (Fig. 2).

Fig.2: (a) untreated *Acanthamoeba* cells, (b) *Acanthamoeba* cells treated with Tb complex, (c) AO/PI stained of viable *Acanthamoeba* cells and (d) Tb-treated *Acanthamoeba*. Magnification was 400x.

Untreated *Acanthamoeba* can be seen as irregular shape of trophozoite with numerous acanthopodia on the surface (Fig. 2a). While *Acanthamoeba* exposed to Tb complex underwent encystment with rounded form of cell with loss of acanthopodia structure as shown in Fig.2b. The most important changes that were observed after AO/PI staining on *Acanthamoeba* were on membrane integrity, nuclear and lysosomal structure. Untreated *Acanthamoeba* was found to display healthy cells as indicated by green fluoresced cytoplasm and nucleus (Fig. 2c). Observation also indicated that the amoeba retain its membrane integrity after being exposed to Tb complex. However, organellar function was disrupted due to different colour emitted after viewed under fluorescence microscope as similar observation also observed in apoptosis event (Fig. 2d).

CONCLUSION

$[\text{Tb}(\text{NO}_3)_3(\text{OH}_2)_3] \cdot (18\text{C}6)$ complex was successfully synthesized and was characterized by single X-ray diffraction. Based on the cytotoxicity test, it was found that the terbium complex could trigger apoptosis in *Acanthamoeba* cells.

c.chiappini@imperial.ac.uk

INTRODUCTION

Access to the cytosol opens up the possibility for direct biochemical interaction within the cell, improving the efficiency of therapy, electrochemistry and biosensing. Unfortunately (or fortunately) the cell has evolved to prevent direct biochemical intracellular interaction with foreign agents, and the strategies developed so far to enable it present significant shortcomings. Mainly, most of the methods available lack versatility, as they are designed solely to deliver a specific cargo to the cell. Microinjection on the flipside provides a continuous interface with the cell granting greater versatility than the other strategy, but it is inherently low throughput and not amenable to *in vivo* conditions.

Translating microinjection to the nanoscale, using large arrays of nanoneedles, provides high throughput strategies to interface with cells, which also minimize toxicity, while retaining versatility and enabling patterning. Nanoneedles can probe excitable cells, deliver biomolecules and nanoparticles to the cytosol², and effectively probe the cell's biochemical activity³. Here we focus on the fabrication of a class of mesoporous, biodegradable silicon nanoneedles⁴ that can be used to build intracellular biosensors and translate nanoneedle-based diagnostics *in vivo* thanks to the biodegradability and elevated biocompatibility of porous silicon⁵⁻⁷.

EXPERIMENTAL METHODS

The nanoneedles were fabricated by combining conventional microfabrication with metal assisted chemical etch to obtain conical nanostructures with less than 100 nm diameter and 4 micron length. The nanoneedles were functionalised with a CFKK-TAMRA peptide, specifically cleavable by Cathepsin B, and with FITC as a pH sensitive fluorophore. Alexafluor 633 functionalisation provided a stable fluorescence reference for ratiometric measurements.

RESULTS AND DISCUSSION

The nanoneedles were tested for their ability to access the cell cytosol. A nanoneedle chip was placed over cells in culture with application of force. Confocal and scanning electron microscopy of focused ion beam milled sections confirmed that nanoneedles stably penetrated the cell cytosol (Figure 1).

The nanoneedle sensor was tested in physiologically relevant buffers in the range between pH 6 and pH 8. The fluorescence ratio between FITC and AF633 increased linearly in the range between pH 6 and pH 8, allowing for calibration of the sensing element.

Figure 1 Nanoneedles penetrate the cell cytosol. (a) SEM of a cell penetrated by a nanoneedle. N indicates the cell nucleus, while C indicates the cell cytosol. Scale bar 200 nm (b) Confocal image of the cell membrane (red), nucleus (blue) and nanoneedles (green). Nanoneedles penetrate across the cell membrane. Scale bar 10 μm.

The efficiency of Cathepsin B at cleaving the substrate and releasing the fluorophore in solution was assessed in physiological buffer. Once successfully interfaced with cells in culture, the nanoneedles functionalized with FITC, AF633, and CFKK-TAMRA were able to discriminate cancer and healthy cells in co-culture by sensing their intracellular pH and Cathepsin B activity (Figure 2).

Figure 2 Confocal image of cancer cells in co-culture with healthy cells. The Cathepsin B sensing element releases TAMRA within cells with active Cathepsin B in the cytosol inducing the fluorescence of cancer cells (in yellow), while healthy cells do not fluoresce (nucleus in blue). Scale bar 15 μm.

CONCLUSION

Here we demonstrated the assembly of a porous silicon based nanoneedle platform capable of sensing the intracellular environment of cells in culture, with the ability to monitor protease activity and intracellular pH, and employ those measurements to detect cancer cells in co-culture.

INTRODUCTION

Upon vascular injury the natural response of the body is to limit blood loss via thrombus formation on an exposed protein matrix. Platelet adhesion/activation in such conditions is directly dependent upon adherence of the blood protein von Willebrand Factor (VWF). VWF binds to the exposed sub-endothelial extra cellular matrix (ECM) which consists mostly of collagen fibres. Platelets tether and adhere to the bound VWF and initiate thrombus formation. However, an inability in certain patients to regulate this process results in conditions such as von Willebrand disease (VWD). The lack of a physiologically relevant diagnostic method to detect such conditions is a major concern¹. This work reports the development of a synthetic biomimetic surface with chemical and morphological properties designed to entrap VWF from blood. The interactions of platelets from the same patient with their bound VWF are then monitored within a representative assay platform allowing for patient specific treatments. A polymer demixing spin coating methodology has been shown to produce a topography representative of that encountered by VWF *in vivo*². By tailoring and optimizing this surface condition, the potential for diagnosis of conditions such as VWD and other platelet orientated cardiovascular diseases has been addressed.

EXPERIMENTAL METHODS

Polystyrene (PS) and PMMA (Sigma, UK) were dissolved at a 50:50 ratio at concentrations of 1%, 3% and 5% w/v in chloroform. The solutions were spin coated onto clean glass coverslips at 6000 rpm for 60s. Resultant morphology was characterised using atomic force microscopy (AFM) and scanning electron microscopy (SEM). Surface chemistry was evaluated by X-ray photoelectron spectroscopy (XPS) and water contact angle. To further mimic the *in vivo* conditions, plasma modification and protein printing of collagen were applied to the polymer demixed surfaces. Blood was perfused through a novel laser patterned fluidic device at a typical arterial shear rate of 1500s⁻¹. Platelet adhesion was observed via real time fluorescent microscopy. The response of platelets to the captured autologous VWF was compared to that on a pooled human purified VWF positive control. Inhibition of platelet binding, utilizing antibodies that block VWF binding sites was performed to ensure that the platelet activity was a result of interaction with captured VWF.

RESULTS AND DISCUSSION

Detailed characterisation of the demixed surfaces showed a relationship between polymer concentration and resultant surface feature size. AFM analysis showed that the 50:50 ratio results in a pitted morphology while the XPS results indicated a surface chemistry almost identical to that of pure PMMA. This would suggest

that the PMMA has formed a raised surface layer due to its dewetting from the PS particles. Platelets were seen to bind well to this surface when compared to the positive control signifying the entrapment of VWF from the circulating blood. This effect is strongly corroborated by the results of the inhibition study with complete absence of platelet adhesion observed after supplementation with any of the (VWF/platelet) blocking antibodies. This data confirms that the featured surface is capturing circulating VWF.

Fig 1: A) Platelet adhesion of non-supplemented and B) AK2 antibody supplemented blood C) AFM of the topography and D) Platelet surface coverage for 3 polymer concentrations.

Based on the rate and percentage of surface coverage the 3% PS/PMMA demixed solution was seen to produce the optimum topography for platelet adhesion.

CONCLUSION

Analysis of dynamic platelet behaviour indicates that a surface created by the PS/PMMA demixing process has the capacity to capture circulating VWF from blood. Furthermore, surfaces produced by spin coating a 3% polymer solution have a sub-micron to nanoscale topography capable of entrapping an individual's VWF and using this to measure their platelet interactions thereon. This is significant as, for the first time, a patient's own unique interactions can be observed under dynamic shear. This is a considerable milestone in the development of a diagnostic for platelet function and the transition towards personalised medicine.

INTRODUCTION

In the present work the use of trimethyl chitosan (TMC), a partially quaternized chitosan (CH), is proposed for the development of a multi-component gene vector targeted to neurons of the peripheral nervous system. Contrary to CH, TMC has fixed positive charges and consequently it is soluble at wider pH range. This should allow the preparation of stable particles in physiological conditions, one of the major limitations of the use of CH as a gene delivery vector^{1,2}. Finally, we used molecular recognition force spectroscopy (MRFS)³ to find the optimal ligand density in the functionalized nanoparticles that mediate maximal neuron cell-specific interaction.

EXPERIMENTAL METHODS

TMC (Mn=43 kDa, DA=11% and quaternization degree of 30%) was used to prepare TMC:DNA complexes. Unmodified CH was used as control. The resulting particles were characterized in terms of size and zeta potential, complexation (SybrGold assay) and transfection (FACS) efficiency. The internalization and intracellular localization of the particles was assessed by imaging flow cytometry (ImageStream^X, Amnis, Millipore) at different time-points (0.5 to 24h). TMC was further modified with thiol groups to prepare neuron-targeted nanoparticles. The 50 kDa non-toxic fragment of tetanus toxin (HC) was grafted to the binary complex via a bi-functional poly(ethylene glycol) (PEG) linker reactive for the thiol moieties in the polymer. For the MRFS experiments either HC or nanoparticles with different densities of HC were tethered to an atomic force microscopy (AFM) tip via flexible PEG linkers. Measurements were carried out using a PicoPlus (Agilent) AFM instrument in both neuronal and non-neuronal cell lines (control).

RESULTS AND DISCUSSION

TMC complexes present higher stability under physiological conditions than CH complexes, resulting in decreased average sizes, lower polydispersion and higher DNA condensation ability. Accordingly, the transfection efficiency of the TMC particles was 15-fold higher, in comparison to CH polyplexes. When assessing the internalization process, TMC nanoparticles were found to be more abundant in the cell cytoplasm at all time-points tested (Fig.1), while CH complexes, especially at the earlier time-points, were predominantly associated to the cell membrane. In this way, at the longest time-point tested, the overall cellular uptake was 16-fold higher for TMC nanoparticles. The amount of vesicle-loaded nanoparticles per cell was also higher for TMC complexes. Moreover, after 2 h of incubation, DNA vectorized within TMC nanoparticles present higher co-

localization with cell nuclei. When taking into account the population of cells that internalized the nanoparticles, it seems at earlier time-points that for the nanoparticles based on CH a higher % of DNA in relation to the total internalized co-localizes with cell nuclei. This result is probably due to their instability in the physiological milieu (SybrGold assay). However, the total amount of DNA present in cells was always lower for CH nanoparticles, since they were less internalized (Table I).

Fig. 1. Representative image acquired on ImageStream^X.

Table I. Percentage of YoYo⁺ cells at 2h. N/C (nucleus/cytoplasm).

	Cytoplasm	Nucleus	N/C (%)
CH	4.7 ± 1.3	0.3 ± 0.1	6.3 ± 0.2
TMC	77.0 ± 2.6	2.8 ± 0.6	3.6 ± 0.3

The uptake of the targeted nanoparticles significantly decreased in non-neuronal cell lines, indicating an increased specificity to neuronal cells. In order to maximize the targeting potential of the nanoparticles, MRFS studies are being conducted. The results obtained so far confirm the interaction between HC and its receptors on neuronal cells, with a binding probability (BP) of 16.5. Both the blocking of neuronal cells with free HC or the measurement in non-neuronal cells resulted in a significant drop of the BP, confirming the specificity of the interaction (Fig. 2).

Fig. 2. AFM force-distance cycle curves. A single molecular unbinding event at 80 pN binding force between HC and ND7/23 cells. The inset shows a force-distance cycle measured after receptors blocking.

Similar experiments are now undergoing, using tips bearing nanoparticles with different densities of HC. One expects to extrapolate from the BP of the different formulations the nanoparticle gene-vectoring capacity.

CONCLUSION

The fixed positive charges on TMC facilitated their association with DNA in physiological conditions, yielding more stable particles. This resulted in higher internalization levels and DNA vectoring to the nucleus, resulting in a more efficient transfection of cells. Moreover, the functionalized particles presented an increased specificity towards the neuronal population.

INTRODUCTION

Neuroelectrodes are susceptible to deterioration via scar encapsulation following implantation. "Intelligent nanosurfaces" which mimic the biological length scale may prevent this deterioration via the modulation of protein adsorption and cell adhesion. Nanotopography may significantly enhance electrode performance via enhanced charge transfer.

Here we describe a self-assembly process for the production of aligned and dense arrays of silicon nanopillars using block copolymers. We discuss the effect of the surface modifications on cell-substrate interaction in vitro and how they may enhance electrode charge transfer and improve neuron/electrode integration.

EXPERIMENTAL METHODS

Polystyrene-*b*-ethylene oxide (PS-*b*-PEO) diblock copolymer was dissolved in 1 wt% toluene. The thin film was formed by spin cast and annealed at 50 °C exposed to toluene/water (1:1). The film was immersed at 40°C for 15h to obtain activated film. Different concentration iron (III) nitrate nonahydrate was dissolved and UV/Ozone treatment was used to oxidize the precursor and remove polymer. Surface morphologies were imaged by scanning probe microscopy in tapping mode and scanning electron microscopy. Electrochemical Impedance Spectroscopy was used to evaluate the charge transfer rate of the substrate. The effect of the surface modifications on cell-substrate interaction was carried by the culture of SH-5YSY neuroblastoma onto the surfaces and evaluating the metabolic activity (alamar blue®) for 1, 7 and 14 days.

RESULTS AND DISCUSSION

Figure 1. AFM topographic images of PS-*b*-PEO after annealing. The FFT image indicating a periodicity of 38 nm. b) After iron oxide inclusion to PEO (dark domains) to enhance the etch contrast. c) After UV/Ozone exposure to remove the matrix polymer (PS). The white domains are iron oxide arrays.

The resultant film is of regular thickness with no signs of de-wetting and is well-ordered across the entire substrate. The measured average centre-to-centre cylinder diameter is 47 ± 9 nm with a PEO cylinder height of 63 ± 20 nm and diameter of 23 ± 9 nm.

Figure 2. After pattern transfer to Si substrate following 10 s Si etch (C4F8/H2) + 90 s Si etch (C4F8/SF6) in ICP/RIE. b) Electrochemical impedance measurements. Si Nanopillar substrates were observed to reduce the electrical impedance relative to Plainer Silicon substrates ($n=3$).

Figure 3. Neurospecific differentiation was achieved up to period of seven days in culture a) Plainer Silicon b) Nanopillars Silicon c) Magnified image showing focal adhesions (white arrows). Results of % of cell growth indicate SH-5YSY cells adhere and proliferate on Nanopillars Si Silicon Substrates (T.C: Tissue Culture)

CONCLUSION

We have fabricated sub-20 nm pillar features in silicon using a block copolymer mask technique. The impedance of the plainer and nanopillars silicon substrates was evaluated showing a remarkable reduction in the impedance magnitude when the nanopillars were present.

In addition, the adhesion and proliferation of SH-5YSY cells on the substrates was assessed resulting in a viable cell growth on the nanopillars silicon substrates as well as the plainer silicon. Furthermore, preliminary results indicate that neurospecific phenotype was maintained and focal adhesion formation induced on control and experimental substrates up to seven days in culture.

INTRODUCTION

To close the wound, some kinds of tissue adhesives have been developed to shorten surgical operation time. However, these adhesives still have some disadvantages on the bonding strength and biocompatibility. Especially for the bonding strength, adhesive bonded with soft tissues is exposed in quite adverse environment, because about 70 % of our body is made up with water, and body fluids spill out during surgery. To solve these obstacles, the molecular design of tissue adhesives which can bond moisture-containing tissues has been required. We developed hydrophobically modified gelatin (hm-Gltn)-based injectable adhesive and clarified that hm-Gltn adhesive with low modification ratio strongly bonded porcine arterial media compared with original Gltn-based ones¹⁻⁵. We also found that the flat films fabricated with hm-alkali treated-Gltn (hm-AlGltn) bonded strongly onto soft tissues. The results suggested that porous films composed by hm-Gltn will also bond soft tissues strongly. On the other hand, it is well-known that porous materials composed of naturally-derived polymers, synthetic polymers and their composites can work as scaffolds for tissue regeneration. Based on those backgrounds, porous films were fabricated with hexanoyl (Hx: C₆) group modified AlGltn (HxAlGltn) by salt leaching method, and the bonding ability, fibroblast viability, and biocompatibility of the porous films were compared.

EXPERIMENTAL METHODS

HxAlGltn was obtained by reaction between Hx chloride and amino group of AlGltn (Figure 1). The modification ratio of HxAlGltn was determined using 2,4,6-trinitrobenzoic acid (TNBS). For the preparation of porous films, HxAlGltn was dissolved in 10 % lactic acid/ dimethyl sulfoxide (DMSO) and mixed with various amount of NaCl. Trisuccinimidyl citrate (TSC) was then added to crosslink HxAlGltn followed by immersion in cold water to dissolve NaCl and to remove by-product such as N-hydroxysuccinimide and then freeze-dried to fabricate porous HxAlGltn films ((P)HxAlGltns). Porous AlGltn films ((P)AlGltns) were also fabricated by similar protocol. Porosity, bulk strength, bonding strength onto porcine intestine, L929 cell viability and biocompatibility of the porous films were evaluated.

Figure 1. Reaction of Hx chloride to amino group on AlGltn molecule to obtain HxAlGltn.

RESULTS AND DISCUSSION

Amino groups of AlGltn were successfully modified with Hx groups. From the determination of residual amino groups in AlGltn by TNBS method, 27% of amino groups in AlGltn were reacted with Hx chloride (27HxAlGltn). Using 27HxAlGltn, (P)HxAlGltns those porosities were ranging from 1 to 65% were successfully obtained as shown in Figure 2. The porosities of (P)AlGltns and (P)HxAlGltns were proportional to the amounts of NaCl in those initial mixture solutions. Also, both (P)AlGltn and (P)HxAlGltn films with high porosity showed good water absorbency. From the mechanical/ adhesive strength measurement, it was clarified that (P)HxAlGltns were weak in bulk stiffness compared with (P)AlGltns, however, each (P)HxAlGltn film bonded with porcine intestine three times stronger compared with (P)AlGltn films. On the other hand, proliferation of L929 cells on (P)HxAlGltns was superior to (P)AlGltns with any porosities. Immunostaining after rat-subcutaneous implantation of porous films revealed that much CD34 marker and von Willebrand factor were expressed around the (P)HxAlGltn films indicating that (P)HxAlGltn film facilitated angiogenesis compared with (P)AlGltn.

Figure 2. Macro/ micro images of (P)HxAlGltns fabricated without (a) or with (b, c) NaCl. The diameters of the discs were 1 cm.

CONCLUSION

(P)HxAlGltns were fabricated by salt leaching method. Compared with (P)AlGltns, (P)HxAlGltns were superior in bonding with porcine intestine, L929 cell viability and angiogenesis in rat subcutaneous tissue. These results suggested that (P)HxAlGltn can work as an adhesive material as well as a scaffold for tissue regeneration.

Development of PLLA/BTO Nanofiber Sheet for Bone Tissue Engineering

A. Yamano¹, Y. Morita² and E. Nakamachi²

² Faculty of Life and Medical Sciences, Doshisha University, Japan, ymorita@mail.doshisha.ac.jp

INTRODUCTION

Scaffold for bone regeneration requires suitable structure for cell adhesion, cell proliferation and early bone formation. In this study, we fabricated biocompatible and biodegradable poly-L-lactic acid (PLLA) nanofiber sheet that mimic nanostructure of natural bone to enhance cell adhesion and cell proliferation by an electrospinning method. Electrical properties of bone are closely related to activity of bone cells and bone formation. Therefore, it is expected that stimulation of surface potential generated on the nanofibers promote cell proliferation and bone formation by adding a piezoelectric material into the nanofibers. We used BaTiO₃ (BTO) nanoparticle which is a ferroelectric material and is a lead-free material. The purpose of this study was to develop PLLA/BTO nanofiber sheet for bone tissue engineering.

EXPERIMENTAL METHODS

Electrospinning condition optimization: Mixed solvent of 1,1,1,3,3,3-hexafluoroisopropanol and 1,3-dioxolane were used to PLLA into 10 and 12 w/v% solution at room temperature. The PLLA solution was electrospun on a copper plate target to fabricate nanofiber sheet. The flow rate is 32, 96 and 159 $\mu\text{L}/\text{min}$. The surface morphology of PLLA nanofiber sheet was observed by a scanning electron microscope (SEM).

Fabrication of PLLA/BTO nanofiber sheet: PLLA and BTO nanoparticles were dissolved in the mixed solvent. Concentration of solution were 10 and 12 w/v% and PLLA/BTO ratio were 1/0, 16/1 and 6/1. PLLA/BTO solution was electrospun on a copper plate target to fabricate nanofiber sheet at the optimum spinning condition. The surface morphology of PLLA/BTO nanofiber sheet was observed by SEM. Distribution of BTO nanoparticle in the nanofiber was observed by a transmission electron microscope (TEM). Osteoblast-like cell (MC3T3-E1) were seeded at density 1.0×10^4 cells/cm² on each nanofiber sheet and cultured for 15 days to investigate cytotoxic of BTO nanoparticles.

RESULTS AND DISCUSSION

Table.1 shows the fiber diameter of the PLLA fiber. The diameters of fiber obtained from 10 w/v% solution were lower than those obtained from 12 w/v% solution under all flow rates. Though the diameters of fibers obtained from 10 w/v% solution were less than 1 μm at all flow rates, beads were observed in nanofibers at the flow rates of 96 and 159 $\mu\text{L}/\text{min}$ as shown in Fig.1. Therefore, solution concentration of 10 w/v% and the flow rate of 32 $\mu\text{L}/\text{min}$ were obtained as optimum condition. Figure.2 shows the SEM images of PLLA/BTO nanofiber sheet fabricated under the optimum condition. The fiber diameter of PLLA/BTO

(1/0), PLLA/BTO(16/1) and PLLA/BTO(6/1) nanofiber sheets were 601 ± 180 , 617 ± 172 and 573 ± 141 nm respectively, and there were no significant differences among all PLLA/BTO nanofiber sheets. Addition of BTO nanoparticles did not affect to the fiber diameter. According to TEM observation, BTO nanoparticles were dispersed uniformly in both PLLA/BTO nanofibers, and the density of BTO nanoparticle in PLLA/BTO(6/1) nanofiber was higher than that in PLLA/BTO(16/1) nanofiber. Since DNA amount and ALP activity of MC3T3-E1 increased with cultivation days for all nanofiber sheets, and PLLA/BTO nanofiber sheet had no cytotoxicity.

CONCLUSION

PLLA nanofiber sheet with uniformly dispersed BTO nanoparticles was developed in this study. PLLA/BTO nanofiber sheet had biocompatibility for cell culture.

INTRODUCTION

Scaffolds with high surface area to volume ratio have attracted much attention when used for filtration industry, drug delivery system, sensor, and tissue engineering¹. Electrospun technology can generate nanofibrous scaffolds with high surface area to volume ratio. While, the surface of fibers fabricated via electrospinning is smooth, typically. Nanofibers with porous surfaces can make more advantages for their variety of applications. Phase separation and leaching method can generate porous fibers with high porosity². The aim of this research is to generate high porous poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV) nanofibrous scaffolds through leaching hydro-soluble polyethylene oxide (PEO). The application of the porous scaffolds in bone regeneration has been explored.

EXPERIMENTAL METHODS

Electrospinning method was chosen to fabricate PHBV/PEO composite nanofibers. The procedures are as follows: 2% PHBV and PEO blend solution with different weight ratio (PHBV:PEO = 9:1, 8:2, 7:3, 6:4, 5:5) was made using 2, 2, 2-trifluoroethanol (TFE), which was fed into one syringe with 6# needle and continually driven by an advancing pump at a speed of 5 mL per hour. A 12 kV high DC voltage was applied between the metal needle and the collector at a distance of 30 cm. Films of the blends with the same ratio above were prepared by spin coating method.

Obtained five kinds of nanofibers and films were immersed in simulated body fluid (SBF) for 4 weeks and SBF was changed every 3 days. Four weeks later, SEM was used to observe the morphology of samples' surfaces and porosity of them was calculated using ImageJ software. Results are presented as mean \pm standard deviation from 10 counts for each kind of nanofibers. Weight loss of nanofibers samples was tested at the time points of 0, 2, and 4 weeks. Viability of bone marrow-derived mesenchymal stem cells (MSCs) cultured on nanofibrous surface was measured by Cell Counting Kit-8 (CCK-8, Dojindo, Japan) according to the manufacture's protocol. Six parallel repeats were tested for each sample. Morphology of MSCs on nanofibrous surface was observed by SEM.

RESULTS AND DISCUSSION

Porous PHBV nanofibers were obtained through immersing PHBV/PEO composite nanofibers into SBF for a certain period of time. From SEM images, it can be found that the morphology and diameters of fibers has changed rarely with the increasing of PEO. However, the surface of fibers became porous from smooth and the weight of fibers meshes lost sharply in

the first two weeks and then gradually in the second two weeks after immersed in SBF (Fig.1). The porous percentage of PHBV fibers with different PEO ratio (30%, 40%, and 50%) was 3.13 ± 0.51 , 7.36 ± 1.6 , 10.75 ± 0.56 , respectively. Cellular response cultured on PHBV nanofibrous meshes before and after immersed in SBF has been measured by CCK-8 and SEM. From Fig.2, it can be found that MSCs' proliferation was slowed down when PEO ratio reached up to 50%. Porous surface of PHBV nanofibers after immersed in SBF can enhance cell proliferation.

These results imply that leaching method can generate porous nanofibers conveniently and porosity of fibers can be enhanced by increasing the weight percentage of PEO. Porous property of scaffolds can enhance cell viability.

Figure 1 (A) SEM images of five kinds of PHBV fibers after immersed in SBF for 4 weeks. (A-E): PHBV:PEO = 9:1; 8:2; 7:3; 6:4; 5:5; (B) Residual weight of five kinds of PHBV fibers after immersed in SBF for 2 and 4 weeks

Figure 2 A: MSCs' viability on different PHBV scaffolds without SBF treatment after 1, 3 and 5 days of culture. B: MSCs' viability on different PHBV scaffolds in comparison to SBF treated scaffold denoted as *.

CONCLUSION

In this study, we have fabricated PHBV porous nanofibers through electrospun and leaching method. These obtained porous meshes can increase the adhesion and proliferation of MSCs and can be a good candidate for tissue engineering.

INTRODUCTION

Nanoporous anodized aluminum oxide (AAO) films are a unique class of biomaterials that can be synthesized by anodization of high purity aluminium.^{1,2} In addition to the native structure's topographic and chemical control advantages,¹ these membranes can also be coated with a conductive layer, and hence present electrical, topographic and chemical cues for the modulation of cell-material interactions. In this study we have utilized carbon (C) sputtering onto AAO films to create conductive C nanotube membranes (CNM) which were characterized by electrical, morphological and chemical characterization tools. Substantial neuron proliferation and adhesion was observed for bare AAO, collagen-coated AAO and collagen-coated CNM substrates compared with collagen-treated microplate controls. The CNM characterization studies and cellular data involving viability, adhesion and neurite growth on AAO and CNM will be presented.

EXPERIMENTAL METHODS

AAO films with 300 and 100 nm pores were produced by the two step anodization method² and coated with 10 nm C layer by a GATAN Precision Etching & Coating System. The fabricated CNMs were characterized by AFM, SEM, XPS, Ellipsometer and I-V measurements. PC 12 cell line (American Tissue Culture Collection) was used for cellular studies after they have been differentiated to the neuronal phenotype by the application of neuron growth factor (NGF 2,5S). A WST-1 kit was used to extract cell viability data of one week incubated PC-12 cells under appropriate cell culture conditions. Cell adhesion and neurite growth comparison was conducted by optical microscopy images after the cells were incubated on the AAO and CNM substrates, fixed and then stained with trypan blue.

RESULTS AND DISCUSSION

AAO and CNM substrates were characterized with SEM and AFM micrographs. Fig.1a illustrates AFM image of a CNM membrane showing nanoporous structure of the substrate. Fig. 1b is a depth profile obtained across a linear region on Fig 1a. It demonstrates that the pores are open after C deposition. The presence of this conductive C layer was further confirmed by ellipsometer, XPS, conductive AFM and I-V measurements and they will be presented.

Fig. 2a depicts cell viability data of PC 12 cells incubated on CNM membranes. It illustrates the enhanced cell proliferation obtained on the collagen-coated CNM. Similar results were also obtained from naked and collagen-coated AAO substrates.

Fig. 1. AFM image of a CNM substrate (a), and depth profile (b) across a line in the AFM image.

Fig 2b. is a representative optical image of stained PC 12 cells displaying the neurites formed on the CNM substrates. Preliminary results dictate that the AAO and CNM substrates enhance cell adhesion compared to controls.

Fig 2. a) Cell viability for CNM, b) Micrographs of neurites on CNM (Pore diameter= 300 nm).

CONCLUSION

Conductive CNM substrates were prepared by using AAO templates. After extensive characterization, the neuronal behavior against both AAO and CNM were investigated which were quite promising with increased cellular proliferation and adhesion. Current efforts are comparison of neurite formation for different substrates and under the application of electric field to CNMs.

INTRODUCTION

In tissue engineering the development of optimized scaffolds that promote cell growth and tissue development is crucial. The synthesized biomaterial-scaffolds should provide the appropriate mechanical and biochemical features to facilitate cell attachment, proliferation and differentiation. In the present study we investigated the physicochemical and nanomechanical properties of chitosan, poly(ϵ -caprolactone) and the chitosan-graft-poly(ϵ -caprolactone) copolymer as synthesized and after subjected in degradation process for three and four weeks. Furthermore, we investigated the growth of Wharton's jelly (WJ) mesenchymal stem cells (MSCs) onto these materials.

EXPERIMENTAL METHODS

We synthesized poly(ϵ -caprolactone) functionalized with a terminal carboxylic acid group and chemically grafted it to a chitosan backbone. The graft copolymer was analyzed by ATR-FTIR, ¹H NMR, SEM, and contact angle measurements [1]. For the in vitro study we used passages 1-4 of WJ-MSCs. We isolated Wharton's jelly mesenchymal stem cells from the inner lining of human umbilical cords of physiological labors from informed and consented women, immunophenotypically characterized them, and cultured them for different time periods on the grafted copolymer. We investigated cell morphology by confocal fluorescence microscopy and SEM. For the quantification of cell proliferation we used the PrestoBlue assay [2].

We fabricated two types of samples, thin films on glass substrates, and bulky discoid samples, both for the mechanical and biological testing.

RESULTS AND DISCUSSION

We measured hardness and Young's modulus values, as well as the time-dependent and viscous behavior of the as prepared samples. Furthermore, we introduced corrections on the measured modulus values in order to investigate the effect of viscoelasticity on the measured values calculated by the Oliver & Pharr model. We observed that the grafted copolymer has reduced nanomechanical properties compared to pure chitosan and poly(ϵ -caprolactone), with time-dependent and viscous behavior, attributed to the poly(ϵ -caprolactone) and the poor connectivity of the two compounds. Submersion of the poly(ϵ -caprolactone) and the grafted copolymer in α -MEM cell culture medium indicated

deterioration of the measured mechanical properties, as a result of the samples' degradation. However, after three weeks of degradation, resulting in a 35% weight loss, the grafted copolymer presented sufficient mechanical stability and elastic properties close to the ones reported for soft tissues. Additionally, we seeded Wharton's jelly mesenchymal stem cells onto the copolymeric discoids, and observed a cell proliferation increase after three and seven days in culture.

While the grafted copolymer degrades after 4 weeks in vitro, the developed WJ cell sheets support dense tissue formation as observed from the scanning electron microscopy images and the elevated values of ECM collagen production.

Figure 1 shows a strong tissue formation after four weeks, while the grafted copolymer degrades.

CONCLUSION

The present work shows the successful development of graft copolymeric discs, which demonstrate a strong cell adhesion and growth of WJ MSCs, together with mechanical properties similar to those of soft tissues. These results establish the basis for the potential use of this cell-material combination in soft tissue regeneration. Ongoing investigations on the differentiation of WJ MSCs may support this hypothesis.

Abstract

The purpose of this study is to search natural BMP modulators from TCM and applied it to control stem cell growth for bone formation. After screening from 60 of TCMs by using a surface plasmon resonance system, a potential TCM, *Gu-Sui-Bu*, was selected. *In-vitro* and *in-vivo* studies showed that GSB and *Naringin* could be good natural BMP regulators for bone tissue engineering.

INTRODUCTION

Bone morphogenetic protein (BMP) is a significant growth factor for bone regeneration. In stem cell studies, some research shows that BMP binding with different BMP receptor (BMPR-1A and BMPR-1B) will induce cell to different differentiation. Therefore, BMP is widely used in bone tissue engineering.^{1,2} Unfortunately, BMP binding is so hard to control that BMP still cannot be applied in clinical. Traditional Chinese medicine (TCM) is a high potential matter to regulate BMP signaling.^{3,4} The purpose of this study is to search natural BMP modulators from TCM and applied it to control stem cell growth for bone formation.

EXPERIMENTAL METHODS

In this study, natural BMP modulators were screening from TCMs by using immobilized BMPR and surface plasmon resonance (SPR). Selective TCMs were assessed in BMP signal pathway. Furthermore, TCM and potential compound, *Naringin* were incorporated respectively into gelatin composite (GHG) to form TCM-contained scaffolds. Physical and chemical properties of these scaffolds were analyzed by SEM and HPLC. Finally, these scaffolds were co-cultured with rabbit mesenchymal stem cells in vitro and were implanted into rabbit calvarial defect for bone repair assessment.

RESULTS AND DISCUSSION

Results show that some TCMs affect the binding of BMP and BMPR in SPR experiments. Among these, GSB is a subtle BMP modulator to inhibit the binding of BMP-2 with BMPR-1A and enhance the binding with BMPR-1B simultaneously. Otherwise, the marker compound in GSB, *Naringin*, was assessed by SPR and also showed the inhibition for BMPR-1A binding. More detail information about the mechanism of GSB in BMP signal pathway performed by monitoring phosphorylation of down-stream signals, SMAD proved

that GSB direct stem cell differentiation through inhibiting BMPR-1A signaling. As applying GSB on bone tissue engineering, GSB exhibit higher capacity to slow be released from scaffold and then promote bone formation via osteo-induction. Finally, GHG scaffold and *Naringin*-GHG scaffold were implanted into rabbit calvarial defects respectively. After 4 weeks, rabbits were sacrificed and bone regeneration in the defect were assessed. The defect containing *Naringin* scaffold showed better bone repair in X-ray image and more new bone generated in the histologic section by H&E stain. These results indicates that *Naringin* enhances bone regeneration in vivo. Combining with the results of SPR and Western blotting experiments, *Naringin* caused better bone regeneration results from BMPR-1A signaling block and BMPR-1B signaling directs cells to osteogenesis.

CONCLUSION

In this study, GSB and its marker compound (*Naringin*) can inhibit the binding of BMP-2 and BMPR-1A to control cell differentiation. Furthermore, this binding disturbance blocks BMPR-1A signaling and leads BMPR-1B signaling for osteogenesis. In order to prove this hypothesis, *Naringin* was incorporated into GHG composite to form TCM-contained scaffold for bone tissue engineering. In animal experiment, the bone defect implanted *Naringin* scaffold showed better bone repair and more new bone generated. According to these results, GSB and *Naringin* could be good natural BMP regulators for bone tissue engineering.

Substrate-Mediated Nanoparticle/Gene Delivery to MSC Spheroids and the Applications in Peripheral Nerve Regeneration

Ting-Chen Tseng¹ and Shan-hui Hsu^{1, 2*}

¹Institute of Polymer Science and Engineering, National Taiwan University, Taipei, Taiwan

^{2*}Research Center for Developmental Biology and Regenerative Medicine, National Taiwan University, Taipei, Taiwan
d00549001@ntu.edu.tw

INTRODUCTION

Peripheral nerve injuries are often caused by trauma and may result in a partial or complete loss of motor and sensory functions. Cell transplantation with a nerve conduit is one of the therapeutic approaches. Recent studies revealed that a proper biomaterial substrate such as chitosan may drive the self-assembly of MSCs to form three-dimensional (3D) MSC spheroids¹. These substrate-derived MSC spheroids showed better self-renewal properties, differentiation capacity, and engrafting potential. Our previous study has also shown that nanoparticles (NPs) or genes can be delivered to MSCs during spheroid formation on chitosan-based substrates². The repairing capacities of these substrate-derived spheroids and advantages of simultaneous NP/gene delivery have not been verified *in vivo*. In this study, the effect of substrate-derived MSC spheroids vs. single cells on peripheral nerve regeneration was investigated.

EXPERIMENTAL METHODS

MSCs were labeled with superparamagnetic Fe₃O₄ NPs or transfected with brain-derived neurotrophic factor (BDNF) gene by the substrate-mediated NP/gene uptake. MSCs were combined with a polymeric nerve conduit to bridge a 10 mm transection gap of rat sciatic nerve. The transplantation of Fe₃O₄ NP-labeled MSC single cells or spheroids was tracked by high-resolution (7-Tesla) magnetic resonance imaging (MRI) *in vivo*. The regeneration capacity of MSC single cells, spheroids, or BDNF-transfected spheroids was assessed by functional recovery and histology after 31 days of implantation.

RESULTS AND DISCUSSION

Fe₃O₄ NP-labeled MSC single cells or spheroids in the conduits were successfully tracked by MRI *in vivo*, especially for MSC spheroids. Animals receiving BDNF-transfected MSC spheroids demonstrated the shortest gap bridging time (< 21 days) and the largest regenerated nerve at 31 days (Figure 1).

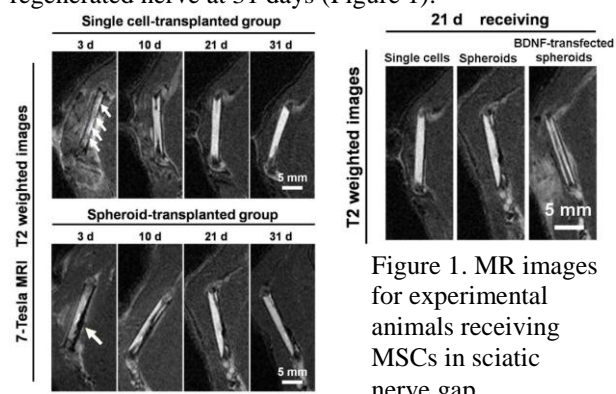

Figure 1. MR images for experimental animals receiving MSCs in sciatic nerve gap.

Compared to MSC single cells, the pristine or BDNF-transfected MSC spheroids significantly promoted the functional recovery of animals. The transplanted MSCs were incorporated in the regenerated nerve and differentiated into non-myelinating Schwann cells after 31 days.

Very early formation of fibrin cable (~ 10 days) and recruitment of MSCs along the cable were visualized for the sciatic nerve gap receiving MSC spheroids in a conduit. The gene modulation associated with neural development, neurotrophic factor, and chemokine receptor expressions may account for the observation and peripheral nerve regeneration. High-resolution MRI tracking of Fe₃O₄ NP-labeled cells offers useful information regarding how MSCs migrate during peripheral nerve regeneration.

CONCLUSION

When combined with a polymeric nerve conduit to bridge the transection gap of rat sciatic nerve, MSC spheroids (especially for BDNF-transfected MSC spheroids) were more conducive to nerve regeneration in comparison with MSC single cells. Animals receiving MSC spheroids or BDNF-transfected MSC spheroids showed significant functional recovery. The transplanted MSCs were differentiated into non-myelinating Schwann cells in the regenerated nerve after 31 days. The substrate-mediated Fe₃O₄ NP labeling for MSCs may be generally used as a bioimaging tool in animal studies. The substrate-mediated gene/NP delivery may equip MSC spheroids with extra values in carrying the therapeutic/diagnostic agents for cell-based therapy.

INTRODUCTION

Age, diseases and trauma cause damages to the central nervous system which may even end up in the creation of gaps and inhibition of signal transfer [1]. Nerve guides are used to bridge these gaps in the treatment of spinal cord injury because the severed axons need to be reconnected during the healing process and the inner architecture of the nerve guides might be important in performing this function [2]. This study aimed to study the effect of organization of nanofibrous fillers on the growth and differentiation of rat bone marrow stem cells (rBMSCs) in vitro. For this purpose, two bilayer conduits, one consisting of aligned fibers and foam (AF-Fo), and the other, consisting of random fibers and foam (RF-Fo), were constructed and tested.

EXPERIMENTAL METHODS

The bilayer nerve guide model consisted of a fiber mat on a foam structure (Figure 1). The poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV) foam was prepared by lyophilization. Aligned (AF) and randomly (RF) oriented PHBV/collagen (2:1) fiber mats were made by electrospinning directly on the PHBV foam. In situ biodegradation test was made in 10 mM PBS pH 7.4 at 37 °C. AF-Fo and RF-Fo nerve guides were seeded with rat bone marrow stromal cells (rBMSCs) and incubated with neural differentiation medium for 7 days. Cell behavior and differentiation to neural cells on these constructs was examined by SEM, fluorescence microscopy, flow cytometry, and neural specific enolase (NSE) ELISA kit.

Figure 1. Bilayer constructs. (A) Aligned PHBV5/Collagen fibers on PHBV5 foam, and (B) random PHBV5/Collagen fibers on PHBV5 foam.

RESULTS AND DISCUSSION

Mercury porosimetry showed that porosity of the PHBV foam was 85%, and the pore sizes were in the range 5-200 nm. The porosity of random fibrous mat and the aligned fibrous mat were 59.7%, and 65%, respectively. These properties were quite suitable for cell growth. The fibers were without any beads and the fiber diameter was in the range of 200-650 nm. The average angle of deviation of the aligned fibers was 46.9 ± 7.3 . In situ biodegradation test revealed minimal weight loss in uncrosslinked guides in 28 days. Cell attachment and proliferation were found to be two times higher on the RF-Fo construct at the end of 7 days. On Day 2, the

cells on AF-Fo type of construct seem to have attached to the scaffolds in an aligned fashion, on Day 16, alignment of the cells became more apparent. While, the cells on the RF-Fo construct had no alignment on Days 2 and 16 as expected, they had grown on the construct in a random fashion (Figure 2).

Figure 2. Fluorescence microscopy of (A) aligned fiber-foam (AF-Fo), and (B) random fiber-foam (RF-Fo) constructs of after Days 2 and 16 of cell culture.

Differentiation of BMSCs was studied with flow cytometry, NSE Elisa kit and immunostaining. It was seen that NSE levels increased in the rBMSC on both AF-Fo and RF-Fo type of scaffolds after 7 days of incubation in the neural differentiation medium. Flow cytometry showed that expression of neural markers, nestin and beta-III tubulin increased almost 2.5 fold after one week culture in the neural differentiation medium. Histological analysis also showed the increased expression of neural markers in the neural differentiation medium.

CONCLUSION

The effect of alignment of the inner architecture within the tubular nerve guides on bone marrow stem cell growth and differentiation showed that random fibers provided a better platform to have high cell numbers. Differentiation of rBMSCs to neurons was observed in both of the constructs when incubated with the differentiation medium. Therefore, both of these constructs have the potential for use as an implant at the nerve injury site.

Designing 3D cell niches exploiting peptide self-assembly

Victoria L. Workman¹ Aline F. Miller² and Alberto Saiani^{1*}

¹School of Material and Manchester Institute of Biotechnology (MIB), University of Manchester, UK ²School of CEAS and Manchester Institute of Biotechnology (MIB), University of Manchester, UK [*a.saiani@manchester.ac.uk](mailto:a.saiani@manchester.ac.uk)

INTRODUCTION

In the last two decades, significant efforts have been made to develop soft materials exploiting the self-assembly of short peptides for biomedical applications.¹ β -sheet forming peptides have been shown to allow the design of highly stable hydrogels with potential application in a range of fields.²⁻⁵ In particular, they offer a flexible platform for the design of 3D cell niches.

EXPERIMENTAL METHODS

We have developed a platform for the design of hydrogels with tailored properties and functionalities exploiting the self-assembly of short (4-10 amino acids) β -sheet forming peptides. The design of these peptides is based on the alternation of hydrophilic and hydrophobic residues. These novel materials have been characterized using a variety of techniques including small angle scattering and rheology.

RESULTS

The self-assembly process of these peptides was investigated and is schematically described in Figure 1. By altering the peptide primary structure, the formulation and the processing conditions the properties of these scaffolds (e.g.: modulus and functionality) can be easily controlled. We were able to design injectable, as well as sprayable, hydrogels that can be used for 3D cell culture as well as *in-vivo* cell delivery.

CONCLUSION AND DISCUSSION

We have developed a platform for the design of 3D scaffolds whose properties can be tailored to accommodate different cells' needs. We have used these novel materials for the culture of a variety of cells including chondrocytes⁵, osteoblasts, fibroblasts as well as embryonic stem cells. For the latter cell type we showed that their pluripotency is retained when embedded within the gels in 3D thus making these materials a potential ideal platform for the controlled differentiation of stem cells. Our results clearly demonstrate that our peptides offer great promise for the design of specific cell niches due to their low immunogenicity and the ability we have to control and tailor their properties.

INTRODUCTION

In a previous study, our results showed that zinc-containing tricalcium phosphate (ZnTCP) can be produced by hydrothermally converting calcium carbonate exoskeletons from foraminifera (Chou et al., 2013). The potential in the use of this material is that it naturally possesses an interconnected and uniform porous network throughout the material and this structure can be preserved during the conversion method (Chou et al., 2007). Furthermore, strontium and magnesium, which are also known metal dopants in bone cell regulations, are part of the material's natural composition (Chou et al., 2012).

In this study, as a first step to demonstrating the application of biomimetic material towards bone tissue engineering, zinc-containing tricalcium phosphate (ZnTCP) was investigated to determine its effect on the growth and osteogenic potential of MSCs.

EXPERIMENTAL METHODS

Material: Calcium carbonate foraminifera exoskeleton material was purchased commercially, cleaned in sodium hypochlorite, hydrothermally converted at 220°C for 48 hours with diammonium hydrogenphosphate adjusted to yield Ca/P molar ratios of 1.5 to produce tricalcium phosphate. Next, 30mg of zinc nitrate hexahydrate was added to the tricalcium phosphate and the samples were heated again to 220°C for 24 hours in a pressure vessel. The material was characterized by XRD and ICP-MS

Cell culture: Bone Marrow stem cells from 5 week-old Wistar rats were harvested and cultured by standard methods⁴. Cell proliferation was assessed by alamar blue staining and osteogenic differentiation by ALP expression on a per unit protein basis.

RESULTS AND DISCUSSION

The main results are shown in Figure 1 below.

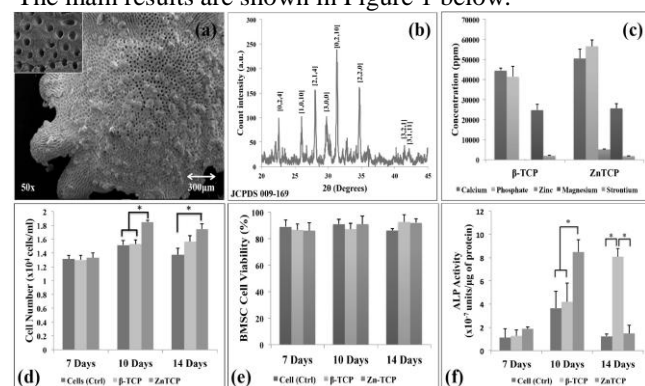

Figure 1. Scanning electron microscopy images showing (a) ZnTCP material with uniform pore distribution and (b) the corresponding XRD pattern matching JCPDS 009-169 for tricalcium phosphate. The chemical composition quantified by ICP-MS (c) shows the preservation of calcium and phosphate with the presence of magnesium and strontium. Zinc was only present after conversion. The growth of BMSCs (d) showing significantly higher cell number after day 10 and in day 14 and the complementing cell viability (e) showing >90% of BMSCs were viable after 14 days. The ALP activity level (f) showed ZnTCP to have significantly higher levels at day 10 suggesting earlier promotion of osteoblast differentiation.

CONCLUSION

In conclusion, this study was able to show that biomimetic ZnTCP can be easily produced at low temperature compared with high temperature sintering and possess the capability to induce and stimulate faster osteogenic differentiation of MSC to osteoblasts compared with β -TCP.

High-Throughput Quantitative Chondrogenic Assay for Stem Cell Differentiation

Amy Prosser¹, Colin Scotchford¹, Virginie Sottile², and David Grant¹

¹ Division of Materials Mechanics and Structures, Faculty of Engineering, University of Nottingham, UK

² Wolfson STEM Centre, School of Medicine, University of Nottingham, UK

expap3@nottingham.ac.uk

An improved cell differentiation assay for chondrogenesis has been developed integrating three robust quantitative measurements that can be used for high-throughput chondrogenic differentiation screening of stem cell populations.

INTRODUCTION

Three-dimensional (3D) cell micromass culture has been used to study *in vitro* chondrogenesis since the 1960s¹. In order to improve the throughput and reliability of this differentiation assay, we developed a cell culture protocol replacing the standard 15ml tube format with 96 well plates. In addition, three robust quantitative methods were developed and assessed to analyse chondrogenesis *in vitro*. Utilising established stains for glycosaminoglycans and proteoglycans, direct in-well methods have been developed. This method facilitates high throughput chondrogenic screening of stem cell and progenitor populations *in vitro*.

EXPERIMENTAL METHODS

Cell Culture – human bone marrow derived mesenchymal stem cells (MSCs)² were pelleted in V-shape plates by centrifugation. Standard culture conditions (Control) contained DMEM supplemented with 10% foetal calf serum, 1% L-Glutamine, 1% non-essential amino acids (NEAA) and 1 % penicillin/streptomycin (P/S) at 37°C and 5% CO₂. Chondrogenic culture conditions (CM) contained high glucose DMEM supplemented with: 1% L-Glutamine, 1% NEAA and 1% P/S, 0.1µM dexamethasone, 50µM ascorbic acid phosphate, 1mM sodium pyruvate, 40µg/ml L-proline, and Insulin-Transferrin-Selenium Supplement. TGF-β1 was used at 10ng/ml. Culture medium was manually replaced every day throughout the culture period of either 14 or 21 days.

DMMB – Pellets were washed and 100µl of water was added to each well, before plates were freeze thawed and papain digested. 50µl aliquots of each sample were transferred into a 96 well plate and combined with 50µl DMMB solution before being read at 540nm absorption.

Alcian Blue - Cultures were fixed in 4% paraformaldehyde before 100µl 1% Alcian solution was added to each well and incubated overnight. Wells were washed with PBS until all unbound dye had been removed. The stain was extracted using 6M guanidine HCl for 2 before quantifying at 650 nm absorbance.

Safranin-O – Cultures were fixed in 4% paraformaldehyde before 100µl Safranin-O in 50mM sodium acetate was added to each well and incubated at room temperature for 20 minutes. Wells were washed with PBS until all unbound dye had been removed before extraction using 10% cetylpyridinium chloride for 20 minutes. Quantification was achieved by reading the absorption of the extracted dye at 530 nm.

PicoGreen DNA Assay – was performed according to the manufacturer's instructions (Invitrogen) on plates that had been freeze thawed to lyse cells. All stain quantification results were normalised to DNA content.

Statistics – were performed in GraphPad Prism using a two way ANOVA analysis with a Tukey correction.

RESULTS AND DISCUSSION

Both Alcian Blue and DMMB stain GAGs and a comparative study was designed to test the sensitivity and reproducibility of the two assays. Figure 1 shows the level of stain per µg of DNA measured by PicoGreen analysis.

Figure 1 shows the level of Alcian Blue and DMMB stain per µg of DNA after 14 and 21 days of culture.

Parallel assays showed the same trend with significantly more stain after 21 days compared to 14 days (Fig. 1) and a significant difference between the control and chondrogenic conditions ($p < 0.01$). TGF-β1 was confirmed to significantly enhance differentiation in these assays, but only at 21 days. Interestingly, the error associated with each datapoint was low, highlighting the improved reliability of these assays.

CONCLUSION

This novel multi-parameter assay can efficiently analyse the kinetics of chondrogenic differentiation of MSCs, and can be used to assess the effects of growth factors, drugs and small molecules on the osteochondral differentiation potential of stem cell populations for regenerative medicine, which is currently under investigation as part of a larger research project.

Ioan Notingher

School of Physics and Astronomy, University of Nottingham, United Kingdom

ioan.notingher@nottingham.ac.uk

INTRODUCTION

A key challenge in tissue engineering and regenerative medicine is understanding the interaction between cells and biomaterials. The design of scaffold materials often aims to modulate the cellular activity and increase therapeutic effect. Therefore, it is important to detect molecular changes in cells that can be correlated with their phenotype and biological functions. Raman micro-spectroscopy (RMS) is a well-established analytical technique that allows label-free measurements on live cells cultured *in-vitro*; the Raman spectra can provide useful information regarding cell viability or differentiation¹. This presentation will report advances in RMS, focused on time- and spatially-resolved measurements of embryonic stem cells during osteogenic and cardiac phenotypes.

EXPERIMENTAL METHODS

Development of an optimised Raman microscope with an integrated environmental enclosure allowed the acquisition of time- and spatially-resolved Raman spectral maps of embryonic cells cultured in defined media to induce differentiation towards cardiac and osteogenic phenotype. The cells were maintained in purpose-built micro-bioreactors on the Raman microscope for 5 days (between days 5 and 9 of differentiation for cardiac differentiation) and 28 days (for osteogenic differentiation). Spatially-resolved spectra were recorded at 24 hours intervals.

RESULTS AND DISCUSSION

For osteogenic differentiation, the time-course Raman spectra of the stem cells detected the formation and mineralisation of bone nodules at days 15-20, as indicated by the increase in the intensity of the Raman band at $950\text{-}958\text{cm}^{-1}$ assigned to the PO43- symmetric stretching of hydroxyapatite (HA). The spatial and temporal analysis of the Raman spectra indicated that initially the bone nodules consist mainly of amorphous HA that transforms into crystalline HA. Amorphous HA is detected at the edges of the bone nodules even at the late stages of mineralisation, suggesting that during the development of the bone nodules, amorphous hydroxyapatite tends to form at the edges of the nodules, followed by a phase transformation.

In the case of cardiac differentiation of embryonic stem cells, the Raman spectra showed that the onset of spontaneous beating of embryoid bodies (EBs) at day 7 coincided with an increase in the intensity of the Raman bands associated to myofibrils and glycogen. The Raman spectral maps had a high positive correlation with the expression of the cardiac-specific α -actinin

obtained by immuno-fluorescence imaging of the same EBs.

Figure 1. Time- and spatially-resolved Raman spectroscopy measurements of embryonic stem cells during cardiac differentiation. (a) Comparison between Raman and immuno-fluorescence imaging of α -actinin (cardiac marker); (b) The time-dependence of the Raman spectral markers for a beating (successful cardiac differentiation) and a non-beating EB.

CONCLUSION

These results demonstrate the potential of Raman spectroscopy for performing non-invasive time-course experiments on live stem cells over periods as long as four weeks and to measure molecular changes related to differentiation.

Substrate Mediated Enzyme Prodrug Therapy

A.N. Zelikin

Department of Chemistry and iNANO Interdisciplinary Nanoscience Centre, Aarhus University, Denmark
zelikin@chem.au.dk

INTRODUCTION: Site specific delivery of drugs is crucial to achieve a higher localized effect and a lower systemic distribution of the therapeutic. Specialized systems for controlled drug delivery are therefore in high demand. Herein, we present a novel paradigm termed Substrate Mediated Enzyme Prodrug Therapy (SMEPT), according to which the drugs are synthesised locally within the biomaterial bulk or the surface coatings. This is achieved using biocatalytic (i.e. enzyme-containing) biomaterials paired with corresponding prodrugs. This ensures localized synthesis of the drug for controlled drug delivery¹⁻⁶.

EXPERIMENTAL METHODS: Biocatalytic hydrogel biomaterials were assembled using poly(vinyl alcohol).¹⁻⁴ Enzyme immobilization was achieved via mixing the protein with the polymer and exerting physical gelation via a treatment with coagulating kosmotropic salt, sodium sulphate. For biocatalytic coatings,^{5,6} enzyme immobilization was achieved using the layer-by-layer polyelectrolyte deposition technique and adsorbing the protein at a nominated location within the multi-layered architecture. The two enzymes chosen for this study were β -galactosidase (β -Gal) or β -glucuronidase (β -Glu). Cell culture was performed using surface-adhered hydrogel biomaterials or polymer coatings using commercially available prodrugs for anticancer and anti-inflammatory agents as well as fluorogenic substrates. Images were obtained using DIC/fluorescence microscopy. Quantitative evaluation was performed via fluorescence readout and standard cell culture assays. Statistics were performed by one-way ANOVA using a Turkey test as means of comparison.

RESULTS AND DISCUSSION: The attractive feature of SMEPT lies in that the same biomaterial, be it a hydrogel or a surface coating, can generate multiple therapeutic agents with dissimilar structure and function. This is possible because e.g. β -Glu would convert any glucuronide into its parent therapeutic agent. The prodrugs can be administered at a nominated concentration (which translates into the concentration of the active agent generated within unit time), and be taken individually, sequentially, or in combination. Using these tools, we used biomaterials to synthesize the rationally designed quantities of drugs for their surface mediated delivery to adhering cells. Concentration of the drug generated by the biomaterial allows to fine-tune the therapeutic effects. Sequential administration of the prodrugs made it possible to use the same biomaterial to generate e.g. anti-inflammatory response in adhering cells today followed by cytotoxic (anti-proliferative) effect at a later time-point.¹ This scenario is relevant to the treatment of atherosclerosis. A highly efficacious mode of drug delivery is that of using combinations of drugs. This is highly important

for anti-cancer and anti-viral treatments as well as for pain management. Using drug eluting biomaterials, combination therapy is tremendously hard to engineer with few if any successes. SMEPT makes it easy and administration of the prodrugs with rationally chosen concentrations produced a combination of drugs resulting in their synergistic therapeutic effect.¹

Using fluidic perfusion chambers, we further demonstrated that SMEPT generates the drugs on demand, at the nominated time (Fig. 1,A). Using this set-up for cell culture revealed a site-specific nature of drug delivery: therapeutic response was higher at the site of drug synthesis than that registered “down-stream” from the biocatalytic coating.⁵

Taken together, our data present SMEPT as a powerful tool for localized drug delivery using biocatalytic biomaterials and coatings.

INTRODUCTION: The concept of using mesoporous nanocapsules as a carrier of nucleic acids, drugs/medicines and biomolecules such as DNA, siRNA for therapeutic applications is a promising approach in medical biotechnology. The wet chemical synthesis method is indeed a new era for designing new materials in the form of nanocapsules for various biomedical applications. The surface modification of nanocapsules is essential for using it in biomedical applications like targeted drug and gene delivery, cancer therapy etc. The drug/medicines molecules are usually loaded into the functionalized/non-functionalized capsules mechanically or with some external forces and delivered into the infected sites for killing/repairing the cells with in a time periods. However, none of the reported nanocapsules for delivery applications are ideal and individuals have their own limitations. Hence, there is a lot of scope to do in the same field.

EXPERIMENTAL METHODS: In this work, mesoporous SiO₂-ZnO nanocapsules have been synthesized using zinc acetate (ZnAc) and tetraethyl orthosilicate (TEOS) through a controlled wet chemical process and ultrasonication where the tiny ZnO nanocrystals are distributed throughout the SiO₂ matrix. We create the micelles first and then **drop wise** a mixture of ZnAc and TEOS was added (feeding rate 100µl/min) under ultrasonication condition. A network of precursors **is** formed, where the mesopores are formed after removal of the micelles through calcinations at higher temperature. Essential characterization were conducted with HRTEM, HRTEM, BET, UV-Vis-NIR, PL and for testing the biocompatibility MTT assay was performed. Finally small biomolecules and DNA molecules were loaded in mesoporous SiO₂-ZnO nanocapsules to form SiOZO-plex and tested the efficiency to kill the cancer cells with a time scale.

RESULTS AND DISCUSSION: This work represents a new materials mesoporous SiO₂-ZnO composite anocapsules of SiO₂ and ZnO with sizes of 40-60 nm and represents their potential applications in encapsulation of small biomolecules for possible uses in drug and gene delivery. The capsule size and morphology have been confirmed through the FESEM and HRTEM. The mesoporous structure of the novel materials has been confirmed through both BET and HRTEM and observed that pore diameter is c.a. 4-6 nm. The BET surface area of mesoporous SiO₂-ZnO was found to be ~ 650 m² g⁻¹. The chemical bonding and

structure have been analyzed through FT-IR spectroscopy and Energy dispersive X-ray spectroscopy (EDX). To demonstrate the biocompatibility, cell viability of the nanocapsules, normal and cancerous lymphocyte cells have been studied in a systematic way. Fluorescent dye (Rhodamin 6G), anticancer drug e.g., Doxorubicin (DOX) and EtBr-labelled DNA molecules were loaded efficiently into the nanocapsules to manifest the mesoporous nature of the nanocapsules and the efficiency to load the small molecules. The release kinetics of Rhodamin 6G, DOX and DNA were studied. The results highlight the potential of novel functional mesoporous SiO₂-ZnO nanoparticles for using as the carrier of drugs and formation of 'SiOZO-plex', a complex of mesoporous SiO₂-ZnO with DNA for gene delivery applications.

Fig. 1: Formation mechanism of SiOZO-plex (complex of mesoporous SiO₂-ZnO with DNA) useful for gene delivery

CONCLUSION: In conclusion, the important of the mesoporous nanocapsules in biomedical applications is growing significantly. Due to the increasing demands of suitable cargo nanocapsules for drug and gene delivery, herein, mesoporous SiO₂-ZnO nanocapsules were synthesized by newly adopted modified wet-chemical-sonochemical synthesis method. The critical advantages of the new nanocapsules are the biocompatibility and efficient ability to load small molecules and DNA inside the mesopores lead to the formation of 'SiOZO-plex', a SiO₂-ZnO and DNA complex. The resulted 'SiOZO-plex' is useful for gene delivery applications.

Estimation of Drug Loading Efficiency in Microspheres by “Shake Flask” Method

C.Y. Tham, Z. A Abdul Hamid¹, Z. Ahmad¹, H. Ismail¹

¹School of Materials and Mineral Resources Engineering, Universiti Sains Malaysia, Seri Ampangan 14300 Nibong Tebal Seberang Perai Selatan Pulau Pinang, Malaysia, szuratulain@eng.usm.my

INTRODUCTION

Drug loading efficiency (DLE) in polymeric microspheres (MS) has always been compared in different fabrication techniques, wherein high loading was desired with minimum drug lost in the system.¹ Thus, an estimation technique of DLE in MS prepared through emulsion and solvent evaporation (ESE) technique was discussed in this paper. The estimation technique applied was a “shake flask” (SF) method using in determining the drug’s partition coefficient.² ESE technique involved two immiscible liquid phases. It was hypothesized that higher drug retention in phase responsible for MS formation will leads to higher DLE in MS. This paper was aimed to investigate the potential of “shake flask” method in estimating the DLE in MS.

EXPERIMENTAL METHODS

Rhodamine B (RhB) and methyl orange (MO) dispersed in distilled water were used as model drugs. In ESE process, firstly, drug model solution dispersed in poly(lactic acid)/dichloromethane solution (PLA/DCM). Next, the mixture was emulsified in poly(vinyl alcohol)/water solution (PVA/water). The emulsion was continuously stirred for 24 hours for solvent evaporation.

In SF process, both immiscible DCM and water was vigorously shakes in flask until not distinct boundary observed. The mixtures were placed in rest for 24 hours for phase separation and stabilization. Phase being studies was extracted and diluted by using respective solvent.

RESULTS AND DISCUSSION

SF method gives promising results in estimating the DLE in PLA MS. The presence of MO in PLA MS was not detectable by UV-Vis spectrometer, while RhB was detected. This outcome was consistent with the SF observation obtained in Fig.1, where MO have limited tendency to dissolve in DCM as compared to RhB.

Fig. 1: Distribution of dye (a) MO and (b) RhB in both water and DCM phase in after SF

The effect of RhB concentration in both SF and PLA MS was studied. The changing trend of DLE for both SF (PLA/DCM phase) and PLA MS was consistent (Fig. 2). As RhB concentration increased, DLE in both SF PLA phase and PLA MS increased. The different in DLE between SF-PLA phase and PLA MS concentration shown in Fig. 2 was due to the presence of PVA in MS preparation. By using SF method in our studies, it was also proven that RhB content in water phase increased in the presence of PVA.

Fig. 2: DLE of SF-PLA phase and PLA MS in vary RhB concentration

CONCLUSION

“Shake flask” method was suitable to be used in estimating the drug loading efficiency in ESE technique. This method can be adjusted according to the materials (e.g. drugs, polymers, solvents and stabilizers) involved in each particular ESE processing. This estimation could use to evaluate the suitability of the fabrication system to encapsulate desired drug molecules.

Suzuki Coupling-Functionalized Boronic Acid Nanoparticles for Drug Delivery

André J. van der Vlies and Urara Hasegawa*

Graduate School of Engineering, Osaka University, JAPAN
andre.vandervlies@chem.eng.osaka-u.ac.jp

INTRODUCTION

We prepared cross-linked phenyl boronic acid (PBA)-containing nanoparticles (NPs) by a simple surfactant-free emulsion polymerization method. By adjustment of the feed ratio of monomers the particle size can be controlled in the range 50-200 nm, which is particularly suited for drug delivery application¹.

The presence of PBA groups on the NPs allow for further functionalization using the well-known Suzuki coupling reaction². Here we present the functionalization of the NPs using aqueous Suzuki reaction and couple the well-known drug Doxorubicin (Dox) via an acid-labile hydrazone linkage³. Upon endocytosis the decrease in pH leads to release of Dox intracellularly. We show that the Dox-NPs are bioactive in different cell lines.

EXPERIMENTAL METHODS

NPs were prepared in phosphate buffer pH 7 by free radical polymerization of PEG-acrylamide, a PBA-containing monomer and cross-linker. The NPs were characterized by dynamic light scattering (DLS) and transmission electron microscopy (TEM). Suzuki couplings were carried out with aryl iodides at 70°C using Na_2PdCl_2 and a water-soluble phosphine ligand as the catalyst and K_2CO_3 as the base. Conversion of the PBA groups was confirmed by the Alizarin Red fluorescence assay. In case of iodobenzoic acid as the coupling partner the carboxylic acid groups were reacted with hydrazine using standard EDC/sulfo-NHS coupling chemistry in MES buffer pH 5. Infrared spectroscopy (IR) was done with lyophilized samples. Dox was conjugated to the NPs in DMF in the presence of CF_3COOH as acid catalyst. Dox-NPs and free Dox were separated by size exclusion column chromatography using Sephadex LH20 and finally dialyzed in phosphate buffer pH 7.4. Dox-NPs were concentrated using an Amicon filter and sterile filtered before incubation with different cell lines. Cell viability was evaluated with the MTT assay.

Figure 1 TEM picture of the PBA-NP (negative staining).

RESULTS AND DISCUSSION

DLS showed that the NPs were 190 nm in diameter and had a spherical shape as confirmed by TEM. Quantification of the number of PBA groups by the Alizarin Red Assay showed that 80-90% of the boronic acid monomer was incorporated into the NPs. Suzuki coupling between the NPs and iodobenzoic acid showed quantitative conversion and the presence of carboxylic acid groups was confirmed by IR. Functionalization with hydrazine and reacting the formed hydrazone with the ketone functionality of Dox afforded Dox-NPs. DLS showed that the size of the NPs was 200 nm. When incubated with RAW 264.7 macrophages and HT-29 colon cancer cell lines Dox-NPs showed a difference in cellular toxicity.

Figure 2 Dox-NP have increased cellular toxicity in RAW 264.7 compared to HT-29 cells.

CONCLUSION

We prepared PBA-containing NPs and showed successful modification using the Suzuki reaction. To show the potential of this NP platform for drug delivery application we conjugated Doxorubicin via a hydrazone linkage and showed cell-type dependent toxicity.

Polymeric Micelles for Hydrogen Sulfide-Based Therapy

Urara Hasegawa* and André J. van der Vlies

Graduate School of Engineering, Osaka University, Japan
urara.hasegawa@chem.eng.osaka-u.ac.jp

INTRODUCTION

With the discovery of important biological roles of endogenously-produced gases, their use as therapeutic agents has attracted growing attention. Among them, hydrogen sulfide (H_2S) has recently emerged as the third gaseous signaling molecule in mammals. H_2S has been shown to regulate inflammation, relax vascular smooth muscles, promote angiogenesis and mediate neurotransmission.¹ Recently, several organosulfur compounds, including dithiolethiones, have been reported as H_2S donors and used to explore the therapeutic potential of this gas.² However, poorly-controlled pharmacokinetic profiles of these donors often result in adverse effects and low therapeutic efficiency which limits their practical applications.

In the field of drug delivery, polymeric micelles as drug carriers have been extensively studied and shown to be powerful in overcoming many intrinsic problems of small drugs including rapid diffusion throughout the body, short circulation time in the blood stream and low bioavailability.

Here we report a novel H_2S delivery system based on polymeric micelles carrying anethole dithiolethione (ADT) moieties which is known to release H_2S in the body via metabolic digestion.

EXPERIMENTAL METHODS

Amphiphilic diblock copolymers containing ADT moieties (PEG-PADT, Figure 1(a)) were synthesized via reversible addition-fragmentation chain transfer (RAFT) polymerization followed by CTA end group removal, deprotection of *tert*-butyl ester group and conjugation with amino group-modified ADT derivatives (ADT- NH_2). ADT micelles were prepared by adding a PEG-PADT/DMF solution dropwise to milliQ water followed by dialysis. The micelles were characterized by dynamic light scattering (DLS) and transmission electron microscopy (TEM). H_2S release from the ADT micelles was detected using ISO-H2S100 hydrogen sulfide sensor. The effects on gardiquimod (GDQ)-induced nuclear factor- κB (NF- κB) activation and the cytokine production in RAW Blue cells were assessed by Quanti Blue and ELISA assays.

RESULTS AND DISCUSSION

PEG-PADT block copolymers were dispersed in water to form ADT micelles. DLS showed that the micelles were monodisperse with a diameter of 36 nm (Figure 1 (b)). Further characterization by TEM confirmed that the polymers formed spherical micelles (Figure 1 (c)).

Figure 1. Characterization of ADT micelles. (a) Chemical structures of PEG-PADT. (b) Size distribution of ADT micelles by DLS. (c) TEM image of ADT micelles.

We investigated the H_2S release property of the ADT micelles. The ADT micelles released H_2S in cell lysate from murine RAW Blue macrophages, but not in PBS and 10% fetal bovine serum. This result indicated that the micelles release H_2S after cellular uptake.

The effect of the ADT micelles in inflammation was assessed using RAW Blue macrophages. Gardiquimod, a Toll-like receptor 7 ligand, was used to induce inflammation. ADT micelles exerted a synergistic effect with gardiquimod, and enhanced NF- κB activation and TNF- α production.

CONCLUSION

We developed a micellar H_2S delivery system. PEG-PADT block copolymers formed monodisperse spherical micelles. The ADT micelles were capable of releasing H_2S in the presence of cell lysate from murine macrophages. The ADT micelles exerted a synergistic effect with gardiquimod and enhanced proinflammatory responses. This H_2S releasing micelles may have potential in immunotherapy and vaccine development.

fnovio@cin2.es

INTRODUCTION

Since the publication of the first nano-/microscale amorphous coordination polymer particles (CPPs) in 2005,¹ new and promising materials based on metal-ligand coordination assemblies (Figure 1) have emerged as novel platforms with application in biomedical fields.² The more recent studies showed the potential applications of this new class of materials for therapeutic and diagnostic uses. They are presented as alternative to other classical nanocarriers (liposome, polymer particle, dendrimer and inorganic particles) due to the nature of the coordination polymer that affords interesting optical, magnetic or catalytic properties. Thus the high tailorability and diversity of the CPPs can generate new multifunctional and biocompatible systems that exhibit high payload capacity to encapsulate different drugs and molecules,³ cell targeting⁴ and drug release in a controlled manner.⁵

EXPERIMENTAL METHODS

Recently in our research group we have been making progress on the control of thermal/chemical stability of the CPPs, the payload capacity for different species and the generation of stimuli-responsive nanoparticles (sensitive to pH changes, temperature or reducing environment). The design and synthesis of nanoparticles containing a specific drug integrated on the structure combined with a drug encapsulated is also reported as a dual nanocontainer with different drug release profiles. The combination of CPP with other nanomaterials such as iron oxide or gold nanoparticles allows applying these hybrid nanoplatforms for imaging or magnetic field/light-induced drug release. We have also performed in vitro cytotoxicity, surface functionalization and stability studies for different combinations to obtain an extensive knowledge about the characteristics of this type of materials.

RESULTS AND DISCUSSION

Although the research on the CPP for theranostic applications is still in an early stage, the recent results suggest the bright future for their application to biomedical field. With critical problems solved such as stability, targeting effect and controlled release profile and wide in vivo testing, CPPs will be the candidate of new generation of smart theranostic agents.

Our expertise, starting from macromolecular science, are developed to search new pharmaceutical strategies in nanomedicine based on rationally designed synthetic coordination polymers that can serve as novel antiviral medicines, detoxification agents, biosensors or drug

carriers. Our ultimate goal is to obtain a fundamental understanding of specific mechanisms of interaction of these nanoplatforms with the biological media to redirect their application to specific therapies/diagnosis. We attack this problem by synthesis of novel CPPs, the study of the physical-chemical properties in biological media and their ability to act as therapeutic or imaging agents.^{6,7}

Figure 1

CONCLUSION

The advantage of the CPPs over the traditional nanoparticles is the unique properties associated to the metal-ligand units that confer novel and interesting properties with wider spectrum of application. We anticipate that results of our research will have a profound impact on the fields of general medicine, immunology and smart drug-delivery systems. Preliminary results indicate that these new nanosystems offer platforms with low toxicity, high cellular uptake, and smart responses to an external stimulus what open a new wide variety of possibilities to be used in therapy and diagnosis.

Potential Use of 7-dehydrocholesterol coated Titanium Surfaces for Soft Tissue Integration of Dental Implants

Manuel Gómez-Florit[†], María Satué[†], Joana M. Ramis and Marta Monjo

Group of Cell Therapy and Tissue Engineering, Research Institute on Health Sciences (IUNICS), University of the Balearic Islands, Spain, m.gomez@uib.es. [†]Both authors contributed equally to the work.

INTRODUCTION

Vitamin D (VitD) plays an important role in the regulation of bone metabolism and immunological reactions. In humans, VitD is derived from dietary sources or made from 7-dehydrocholesterol (7-DHC) in the skin by exposure to ultraviolet (UV) rays. The function of VitD, via the active metabolite 1 α ,25-dihydroxyvitamin D3 (1,25D3), is to regulate the absorption of calcium and phosphorus in the intestine, and their mobilization in bone tissues. Recently, non-skeletal functions of VitD have gained notoriety [1].

Periodontal tissues consist of two hard tissues, bone and cementum, and two soft tissues, gingiva and periodontal ligament. It has been recently shown that gingival fibroblasts (HGF), the most abundant cells in the gingiva, can synthesize the active 1,25D3 [2]. In addition, there are evidences that link low VitD serum levels with increased periodontal inflammation and studies that show a positive effect of VitD on oral health [1].

Previous experiments of our group show that titanium (Ti) coating with UV-activated 7-DHC allow pre-osteoblasts to produce active VitD and to differentiate towards a mature state [3]. Furthermore, our current results prove that the addition of α -tocopherol (VitE) prevent 7-DHC oxidation whilst increase the biological potential of the coating.

The aim of the present study was to evaluate the response of HGF to 7-DHC:VitE coated titanium surfaces for improved soft tissue integration to dental implants.

EXPERIMENTAL METHODS

Machined Ti surfaces were coated with 7-DHC:VitE. Ti was also coated with ethanol (EtOH), 7-DHC or VitE, as controls. Surfaces were then exposed to UV light for 15 min and incubated at 23°C for 48 hours. Three different donors of HGF were cultured for 14 days on the different surfaces (n=6). Biocompatibility of surfaces was evaluated by a cytotoxicity assay and by cell morphology visualization (cytoskeleton and nuclei staining). Then, the expression of different genes was analysed by real-time RT-PCR.

RESULTS AND DISCUSSION

All surfaces were biocompatible although the 7-DHC control group showed increased cytotoxicity (less than 20%). HGF showed typical spindle-shaped morphology on all surfaces and were aligned to the machined texture.

After 14 days of cell culture, 7-DHC:VitE coated surfaces increased the expression of collagen III- α 1, a marker of fibroblastic maturation and scarless wound healing. Changes in the expression of matrix

metalloproteinase-1 (MMP1) and tissue inhibitor of metalloproteinases-1 (TIMP1) did not reach statistical significance. However, MMP1/TIMP1 mRNA ratio decreased on 7-DHC:VitE coated surfaces, suggesting that they may reduce MMP-related ECM destruction. Also, 7-DHC:VitE coated surfaces significantly decreased interleukin-8 mRNA levels, pointing to an anti-inflammatory effect.

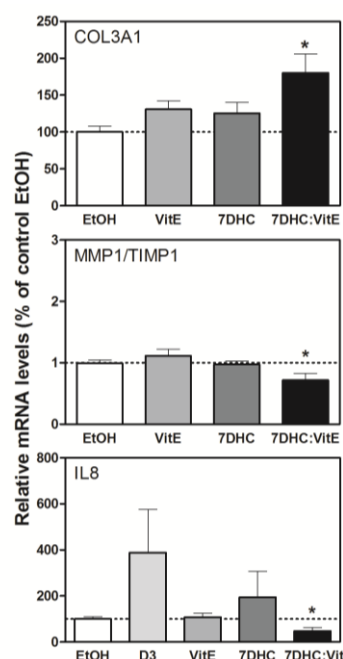

Figure 1. Gene expression levels of HGF cultured on coated surfaces. Data represent fold changes of target genes normalized to beta-actin and GAPDH (reference genes) expressed relative to cells grown on EtOH-coated Ti surfaces that were set at 100 %. Paired t-test was used to assess differences: * $P \leq 0.05$ versus EtOH.

CONCLUSION

These results suggest that UV-activated 7-DHC:VitE has a great potential to be used as a new coating for dental implant abutments to improve soft tissue integration to dental implants.

⁴Department of Medicine Laboratory, Azienda Provinciale per i Servizi Sanitari di Trento, Trento, Italy

INTRODUCTION

The installation of a titanium implant, put the severed mucosa in close contact with the implant surface. During healing, an attachment is formed between the mucosa and the titanium dioxide layer of the implant. Once properly matured, this attachment effectively separates the bone tissue from the oral cavity¹.

Experiments in the dog documented that several weeks are required to allow the establishment of an epithelial and connective tissue attachment to titanium implant¹. Corresponding data in humans are not available.

Recently, we proposed a human model to evaluate the morphogenesis of the mucosal attachment to implants². In this study we aimed at assessing the tissue at implant interface by scanning electron microscopy (SEM).

EXPERIMENTAL METHODS

Patient informed consent was obtained and after implant installation, a custom-designed experimental abutment was connected to the implant. A soft tissue biopsy and the titanium abutment were collected according to the method described by Tomasi et al.² after 12 weeks of tissue healing. The sample was fixed in 4% formalin for 48 h and stored in 70% ethanol solution. After fixation, four incisions, parallel with the long axis of the abutment, were made through the tissue to produce four portions. Each portion was separated from the experimental abutment using the previously described fracture technique¹. Samples were collected in a total six patients and one tissue unit (TU) with its experimental abutment (EA) were imaged in a XL30 FEI-Philips field-emission environmental scanning electron microscope (SEM).

TUs were re-hydrated by graded alcohol series to 100% water before analysis, and imaged in environmental mode at 10–15 keV and 60 to 95% relative humidity. The tissue surface in contact with the abutment was imaged from the apical margin to the marginal side of the biopsy collecting the signal of gaseous secondary electrons (GSE).

EAs were dehydrated, dried, gold sputtered and imaged at 15 keV in high-vacuum mode. Back scattered electron signal was acquired showing compositional contrast between titanium surface and biologic debris.

Figure 1: The experimental abutment at the end of the healing period (a, b). Samples obtained after fixation (c) and fracture technique (d, e)

RESULTS AND DISCUSSION

The sulcular epithelium showed exfoliating cells (Fig 2a). The analysis of the connective tissue interface revealed a surface topography that resembled that of the abutment. Collagen fibres induced a shirking of the sample during imaging (Fig. 2b). Results are in agreement with previous histological data² and were confirmed by the SEM observation of the tissue adhering to EA surface (Fig. 3a). From marginal to apical side, besides plaque on the emergent portion, we found a uncovered titanium band, an area with polygonal mono-layered cells (Fig. 3b) and a thicker tissue with fibrous appearance (Fig. 3c).

Figure 2: Surface of TU at marginal (a) and apical (b) side. Environmental SEM, GSE signal, 1000x.

Figure 3: Surface of EA at marginal (a) and apical (b) side. Dashed line indicate mucosal margin. High vacuum SEM, BSE signal, 250x.

CONCLUSION

SEM characterization of tissue at implant interface showed two different tissue morphologies (epithelium-like and connective-like) on both biopsy and experimental abutment surface. This techniques associated to image analysis can provide quantitative data to complement the histological characterization of the oral mucosa in contact with titanium implants.

Synthesis and Characterisation of Novel Diopside Glass-Ceramics for Dentistry

J. Almuhamadi, N. Karpukhina and M. Cattell

Institute of Dentistry, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, UK
j.m.a.almuhamadi@qmul.ac.uk

INTRODUCTION

Yttria Tetragonal Zirconia Polycrystalline ceramics (Y-TZP) have been stated as a successful all-ceramic system, regardless of the clinical indication¹. However, chipping of the veneering ceramic on zirconia restorations continues to be a problem² and is reported to be the most common clinical failure of these all-ceramic restorations. Rogers et al., 1970³ suggested that compositions which crystallise to form solid solutions are capable of controlling the thermal, chemical, physical and mechanical properties of the produced material. Diopside (Di, $\text{CaMgSi}_2\text{O}_6$) is an important member of *clinopyroxene* mineral family. It has a single chain silicate structure and is known to form a solid solution on cationic substitution for Ca^{2+} and Mg^{2+} . In particular, the solid solution forms as a result of coupled substitution of $\text{Ca}^{2+}/\text{Mg}^{2+}$ with $\text{Na}^+/\text{Al}^{3+}$ when $\text{CaMgSi}_2\text{O}_6$ is diluted with a stoichiometry of $\text{NaAlSi}_2\text{O}_6$. The aim of the study was to produce new diopside glass-ceramics based on this solid solution to prevent chipping of zirconia restorations.

Objectives were to:

Synthesise new glass/glass-ceramic formulations.

Characterise/optimize these materials.

Test the biaxial flexural strength.

EXPERIMENTAL METHODS

A series of glass compositions with varying amounts of sodium and aluminium oxides were synthesised using a melt-quench route, re-homogenised and processed into powders. Glass powders with a controlled particle size ($\text{PS} < 125\mu\text{m}$) were heat treated via two-step heat treatment cycles (nucleation and crystal growth) then held for 1 hour, quenched and ground to a powder. Glass-ceramic disc specimens ($15 \times 2\text{mm}$) were fabricated via sintering at variable sintering temperatures and holding times. Disc specimens ($n=30$) were tested using the Biaxial Flexural Strength (BFS, ball on ring) at a crosshead speed of 1mm/min . The BFS data were statistically analysed using (Dunn's multiple comparison tests, $p < 0.05$). Glass-ceramics were characterised using X-ray Diffraction (XRD), Dilatometry, Solid-State Nuclear Magnetic Resonance (NMR) and Scanning Electron Microscopy (SEM).

RESULTS AND DISCUSSION

XRD results of glass-ceramics revealed the diopside as the major crystalline phase. Platelet and dendritic diopside crystals with no signs of matrix micro-cracking were produced. Nano-scale fibres were also visible in the glassy matrix after sintering. Glass-ceramic (75Di-25Jd) and (50Di-50Jd) showed significantly higher BFS than all tested glass-ceramic groups ($p < 0.05$).

The mean (SD) and the median (Q1, Q3) BFS MPa results of the test groups are given in Table 1 where different superscript letters indicate significant differences between groups ($p < 0.05$). The measured thermal expansion coefficient of sintered specimens ($\text{TEC} \times 10^{-6} \text{K}^{-1}$, $100-400^\circ\text{C}$) was; 100Di-0Jd: 9.12, 85Di-15Jd: 9.22, 75Di-25Jd: 9.11, 50Di-50Jd: 8.65, 25Di-75Jd: 8.66. From the ^{27}Al NMR a sharp crystalline peak at -4ppm corresponding to Al(VI) species is present in all glass-ceramic formulations which was attributed to the formation of diopside solid solutions.

Glass-ceramic	Median BFS MPa (Q1, Q3)	Mean BFS MPa (SD)
100Di-0Jd	58.04 ^a (53.33, 61.22)	57.80 (7.26)
85Di-15Jd	125.14 ^b (105.17, 134.98)	119.62 (20.42)
75Di-25Jd	175.33 ^c (160.05, 204.33)	180.68 (28.62)
50Di-50Jd	164.45 ^c (145.22, 182.37)	168.11 (32.82)
25Di-75Jd	117.84 ^b (100.10, 143.38)	118.40 (29.44)

Table 1: BFS results of the experimental glass-ceramics

The results suggested that the formation of diopside solid solution led to remarkable increases in the BFS and TECs values in comparison to the 100Di-0Jd glass-ceramic which make the produced glass-ceramics suitable for all-ceramics diopside restorations.

CONCLUSION

New diopside glass-ceramic with acceptable mechanical strength and TECs compatible with Y-TZP ceramics were successfully produced. These glass-ceramics can be useful as a veneering material for Y-TZP ceramics and for all-ceramic diopside restorations. The produced glass-ceramics might also be a potential candidate for bone replacement materials.

Functionally graded Guided tissue regenerative (GTR) membrane for periodontal lesions

S Qasim¹ R Delaine-Smith, A. Rawlinson, I. Rehman¹

¹Materials Science and Engineering Department, KROTO Research Institute, University of Sheffield, United Kingdom
sqasim@sheffield.ac.uk

INTRODUCTION

Chronic periodontal lesions largely heal by repair, with the formation of a long junctional epithelium and a limited amount of true regeneration of lost periodontal ligament, cementum and alveolar bone. Recently, a considerable amount of research has focused on increasing the regeneration of lost supporting tissues by the use of Guided Tissue Regeneration (GTR) membrane or the incorporation of biologically active molecules on the surface of membranes which will encourage regeneration. Both non-resorbable and resorbable GTR membranes are available, but with the limited success rate.¹ Consequently, there is a need for further research to develop bioactive functionalized GTR membranes (FGM) that may lead to improved regeneration of periodontal tissues lost due to the progression of disease.^{1,2}

The aim of this work is to design a biologically active, spatially designed, and functionally degradable occlusive membrane for periodontal lesions.

EXPERIMENTAL METHODS

Bioactive membranes, with controlled porosity and non-porous layers were developed using a combination of natural polymer Chitosan (CH) and Hydroxyapatite (HA). CH with two different molecular weights was used. Characterization was performed to analyze physiochemical and biological properties of the membrane. In-vitro tests (Alamar blue) assessed the viability and biocompatibility of the prepared specimens.

RESULTS AND DISCUSSION

The CH:HA membranes had a high degree of segregation of CH to HA. Other components of the FGM prepared were porous membranes and fibres obtained through freeze gelation and electrospinning. Scanning electron microscopy images showing prominent HA particles visible on one side of the membranes, freeze gelated membranes with a pore size of 150 to 200µm. (Figure 1). Highly oriented and random chitosan fibers were obtained by using ultrahigh molecular weight polyethylene oxide as a cross linker. Fourier transform infrared spectroscopy data (Figure 2) showed high degree of segregation in between the polymer and hydroxyapatite from the spectra collected on the top and bottom surfaces of various combinations used. Cell viability data (Figure 3) showed low molecular weight CH:HA 30:70 membranes had higher viability over a 7 day time period..

Figure1. (a, b) Top, bottom surface of CH:HA membranes, (c, d) Top, Cross section freeze gelated, (e, f) Random, aligned CH fibers

Figure 2 Top image of top surface of LMw CH:HA membranes, (a) 100:0 (b)70:30, (c) 50:50, (d) 30:70, Bottom image of bottom spectra (a)70:30, (b) 50:50, (c) 30:70).

Figure 3 Alamar Blue on Day 1, 4 and 7

CONCLUSION

Functionally graded layers were successfully prepared. Membranes had bilayer surface, with CH dominating on top and HA on the bottom surface. Freeze gelated porous membranes and random and aligned CH fibers were prepared using nontoxic solvents. Bottom surface of membranes were biocompatible, which should be of value in periodontal regenerative procedures.

Abstract

Different composite mixtures containing calcia-magnesia have been processed with addition of alumina, silica or zircon. These system powders were formed and fired at two different temperatures. Phase composition, microstructure, and physico-mechanical properties of these composites were determined. The in vitro bioactivity of these sintered composites were investigated by analysis of apatite-formation ability in the simulated body fluid (SBF) using SEM-EDS. The composite compositions termed “I”, “II” and “III” gave clear tendency toward the formation-ability of hydroxyapatite (HA). Composite “I” gave cubic and spindle HA crystallite, however, composites “II” and “III” fired at 1300 and 1400°C were formed typically “cauliflower” morphology and their evaluated physico-mechanical properties are similar to the properties of human cortical bone. Thus, composites “II”&”III” might be a promising bone implant materials. Besides the bioactivity of composite “I”, it contains highly cementing phase (CA) and bioinert (MA) phases, therefore, it might be nominated as a promised bioceramic material for different purposes such as scaffold, bone replacement, bone repair and coating.

Characterisation of Partially-Demineralised Dentine is a Prerequisite for Remineralisation Studies

Eleanor Ashworth*, Cheryl Miller, Christopher Deery and Nicolas Martin

School of Clinical Dentistry, University of Sheffield, UK

*mba07ema@sheffield.ac.uk

INTRODUCTION

There is a wide range of acids involved in the demineralisation of dentine but it is unknown how they differ in their effect on the remaining collagen matrix. There is increasing research interest in the development of a remineralisation technique for the management of partially demineralised dentine that enables the preservation and remineralisation of the affected collagen matrix¹. Understanding the effect of the different acids is key to the development of appropriate remineralisation strategies. Current remineralisation studies of acid-affected dentine are based on the presumption that all acids affect dentine in the same manner. In this way, research models of partially-demineralised dentine with formic acid, phosphoric acid or EDTA have become a ubiquitous standard used for remineralisation studies². The aim of this study is to fully characterise the partially-demineralised dentine matrix following exposure to a range of bacterial, dietary, gastric and laboratory acids.

EXPERIMENTAL METHODS

Dentine blocks were prepared from caries-free human premolars with a slow-speed precision saw. The dentine samples were divided into 8 groups: (1) water storage (control), (2) lactic acid (caries), (3) acetic acid (dietary), (4) phosphoric acid (dietary), (5) citric acid (dietary), (6) formic acid (laboratory), (7) EDTA (laboratory) and (8) hydrochloric acid (gastric). Each sample was immersed in 10 ml acidic solution for 14 days and refreshed every 24 hours. Demineralisation was terminated by alternating washes in 0.1 M cacodylate buffer and distilled water. Collagen integrity was analysed using scanning electron microscopy (SEM), surface micro-hardness (SMH) and hydroxyproline assay. Mineral content was measured using x-ray diffraction (XRD), energy dispersive spectroscopy (EDS) and micro computed-tomography (MCT).

RESULTS AND DISCUSSION

The characterisation techniques reveal a differential effect of the acids on the dentine structure and mineral content. Lactic acid causes the most demineralisation. Following lactic acid treatment, SEM images demonstrate that the collagen network becomes very exposed (Fig.1) and SMH results reveal the greatest decrease in hardness values. Additionally, EDS and MCT data reveal that the mineral content of dentine after treatment with lactic acid decreases the most (Fig.2).

Although lactic acid appears to demineralise the dentine samples the most, it does not appear to damage the

collagen network. EDS and XRD results show that citric acid has the least effect on mineral loss (Fig.4) but the hydroxyproline assay and SEM analysis (Fig.3) suggest that citric acid affects the collagen structure the most severely. Citric acid, in contrast to lactic acid, preserves mineral content but appears to degrade collagen the most.

Figure 1: SEM of dentine after lactic acid treatment

Figure 2: Calcium and phosphorous levels after lactic acid treatment

Figure 3: SEM of dentine after citric acid treatment

Figure 4: Calcium and phosphorous levels after citric acid treatment

CONCLUSION

Dentine demineralisation cannot be characterised by observing the collagen structure or measuring the mineral content alone. Complementary assays that analyse collagen integrity, surface hardness and mineral levels should be undertaken. The acids studied in this investigation have a markedly different effect on the dentine and this should be considered in the development of remineralisation strategies. This is especially relevant for studies that require a partially demineralised dentine model.

INTRODUCTION

An inefficient or inexistent treatment of periodontal disease can ultimately result in tooth loss due to progressive destruction of surrounding soft and hard tissues¹. Despite not being totally predictable or surgically practical², Guided Tissue Regeneration (GTR)³ is the most widely used regenerative procedure for treating this disease. This study investigated the ability of an osteoconductive biphasic scaffold produced by combination of melt electrospinning and fused deposition modelling to simultaneously regenerate alveolar bone, periodontal ligament and cementum. The scaffold's design aimed at maximizing periodontal GTR treatment efficiency as well as the ease of handling by surgeons and commercial viability.

EXPERIMENTAL METHODS

An in-house melt electrospinning device (patent application in preparation) was utilized to produce medical grade polycaprolactone (PCL) (Lactel, USA) electrospun meshes. PCL was electrospun at 80°C, 20 µl/h feed rate, 7 kV voltage and 4 cm tip-to-collector distance. The obtained circular meshes reached 8 mm diameters after 4 min electrospinning periods onto aluminium foil covering the collector. The meshes were then attached to scaffolds produced by fused deposition modelling (FDM) through a quick melt and press-fitting process. The FDM component was composed of medical grade PCL and β -tricalcium phosphate (20% wt) (Osteopore Inc., Singapore), possessed 100% interconnectivity, 70% porosity and a 0/90 degrees lay-down pattern. Prior to attachment to the electrospun mesh and in order to increase osteoconductivity, the FDM scaffold was submitted to a calcium phosphate coating process by successive immersion into sodium hydroxide and simulated body fluid. Scaffold's morphology and coating composition were assessed by scanning electron microscopy (SEM) and X-ray diffraction (XRD) analysis, respectively. Biphasic scaffolds were seeded and cultured *in vitro* for 6 weeks with sheep primary osteoblasts on the FDM compartment and characterized by alkaline phosphatase activity/DNA content quantification, SEM and confocal laser microscopy. Micro computerized tomography (Micro-CT) analysis was also employed to assess the degree of mineralization. The cultured constructs were further tested in an ectopic *in vivo* study in rats. Briefly, the constructs were complemented with the placement

of several sheep primary periodontal cell sheets over the construct's electrospun mesh, attached to a dentin block and subcutaneously implanted into athymic rats for 8 weeks. The construct's *in vivo* performance was assessed by micro-CT and histological analysis.

RESULTS AND DISCUSSION

SEM and XRD analysis showed that the scaffold's bone compartment was homogeneously coated with a 600-800 nm calcium phosphate layer. The periodontal compartment was composed of randomly orientated PCL fibres with diameters of 100-400 µm. It was also visible that the fusion-press-fit scaffold assembly was not detrimental to the physical integrity of each individual component. The *in vitro* cell culture study showed that the coating of the scaffold's bone compartment resulted in significant increase in alkaline phosphatase activity and enhanced mineralization. Similar results were found *in vivo* where scaffold coating resulted in significantly greater bone formation. Histological analysis showed periodontal attachment at the dentin interface and that periodontal compartment's large pore size permitted vascularization of cell sheets. The developed scaffold technology is currently being commercially explored by the startup company Biofabrication Design Solutions Pty Ltd.

CONCLUSION

The studied biphasic scaffold displayed suitable properties for periodontal regeneration and promoted integration of tissues from both compartments. As well, high vascularization levels and tissue orientation were seen in the bone and periodontal compartments, which is of high significance for fibre attachment formation.

Development of a pro-angiogenic cell-delivery vehicle based on RGD-alginate hydrogels

Sílvia J. Bidarra¹, Fátima R. Maia, Joana Gesta, Cristina C. Barrias¹

¹ INEB - Instituto de Engenharia Biomédica, Universidade do Porto, Portugal,
sbidarra@ineb.up.pt

INTRODUCTION

Neovascularization is a critical step towards recovery of injured and ischemic tissues. Cell-based approaches of endothelial cells (EC) transplantation are attractive, but clinical trials have not resulted in consistent benefit. The outcome might be improved by using biomaterial vehicles to protect cells from the harsh in vivo environment, enhancing their survival and engraftment. Alginate hydrogels are ideal candidates to mediate cell delivery and accommodate cells in a 3D microenvironment due to their ECM-like features¹. Embedded in this type of matrix, cells are expected to develop tissue-like order intercellular structures (cell-matrix and cell-cell interactions). This process is dependent on several matrix cues, such as cell-adhesion sites and matrix stiffness, which will in turn modulate cell-cell interactions. The potential of these hydrogels as vehicles for EC and mesenchymal stem cells (MSC)^{2,3} has been previously demonstrated. Considering the reciprocal regulation and functional relationship between both cell types and their role in the angiogenesis process, the aim of this work was to optimize 3D microenvironments for EC and MSC that could be further explored in the co-entrapment of both cell types as a pro-angiogenic therapeutic strategy.

EXPERIMENTAL METHODS

PRONOVA ultrapure sodium alginates LVG and VLVG (hereafter designated as high molecular weight, HMW (≈ 150 kDa) and low molecular weight, LMW (≈ 25 kDa); respectively) with a high guluronic acid content ($>67\%$) were purchased from FMC Biopolymers and further modified through grafting of RGD peptides to promote biofunctionality^{2,3}. Human umbilical vein endothelial cells (HUVEC, ScienCell) and MSC (Lonza) were entrapped within RGD-alginate combined with calcium carbonate, and gel formation was triggered by adding a fresh solution of gluconate delta-lactone. EC and MSC were entrapped alone or in co-culture within RGD-alginate under different conditions: 1 and 2 wt.% alginate with 100% HMW or 50%HMW/50%LMW (HLMW), with cell densities ranging from 5 to 30 million cells/mL and RGD densities from 50 to 250 μ M. Cell viability and metabolic activity were assessed by the trypan blue dyes exclusion assay and the resazurin assay, respectively. Cell morphology was analysed by CLSM (F-actin staining). To assess MSC migration through the hydrogels, cells were first seeded on PS beads that were then embedded in alginate. In some studies, cells were labelled CellTracker Blue (MSC) and Green (EC) and with Ac-Dil_LDL (EC). Fibronectin expression was analyzed by immunostaining.

RESULTS AND DISCUSSION

EC were only able to spread and form multicellular networks when entrapped in the softer matrices (1 wt.% alginate), containing RGD, at high cell densities (≥ 15 million cells/mL in HMW hydrogels, and ≥ 10 million cells/mL in HLMW hydrogels). Under these conditions cell viability remained high ($>70\%$). On the other hand, MSC were able to contract the matrix and form multicellular aggregates within 1 wt.% RGD-alginate (≥ 100 μ M RGD), but not within 2 wt.% RGD-alginate. Cell migration and matrix contraction were facilitated in HLMW as compared with HMW hydrogels (Fig. 1). In view of the previous results, MSC and EC co-cultures in 3D were established using 1 wt.% HLMW RGD-alginate hydrogels. Both cell types were able to rearrange inside the matrix, forming multicellular structures stabilized by a fibronectin mesh. Moreover, EC were able to align into tubular-like structures within these microtissues.

Figure 1. MSC sprouting from PS beads embedded within 1 wt.% HLMW RGD-alginate after 20 days in culture.

CONCLUSION

The combination of soft RGD-alginate matrices with co-entrapped MSC provides an adequate 3D microenvironment for EC, and might be a suitable strategy to create adequate vehicles for EC-based pro-angiogenic therapies.

INTRODUCTION

The inflammatory environment that arises from the immune response towards an infection, or in inflammatory diseases is believed to be detrimental for bone and exert negative effects on bone forming cells and their progenitors, the mesenchymal stem cells (MSCs). At the same time it has been demonstrated that MSCs act on the immune systems by for example suppressing the expression of pro-inflammatory cytokines.¹ Furthermore, monocytes of a pro-inflammatory phenotype, activated by inflammatory stimulus lipopolysaccharide (LPS), secrete both soluble factors and exosomes that have positive effects on the osteogenic response of human MSCs.^{2,3} However, the communication between immune cells and MSCs, especially in the context of regeneration in the presence of a pathogen or other molecules triggering inflammation, is a key process that is incompletely understood. The aim of the present study was therefore to investigate the effects of different immune-stimulatory molecules such as membrane vesicles (MVs), isolated from gram-positive bacteria *S. aureus* and *S. epidermidis* on the osteogenic differentiation and secretory response of hMSCs.

EXPERIMENTAL METHODS

- hMSCs were isolated from bone marrow aspirates taken from the *iliac crest*. The hMSCs were expanded *in vitro* and subsequently osteogenic differentiation was induced.
- MVs were isolated from *S. aureus* and *S. epidermidis*. MVs, and reference stimuli LPS and lipoteichoic acid (LTA) were added to osteogenic cultures of hMSCs.
- The secretion of cytokines by the hMSCs was determined by multiplex assay. Two time points were investigated, 72 hours and one week.
- The progression of the osteogenic differentiation, in the presence of inflammatory stimuli, was evaluated by measurement of ALP-activity and matrix mineralization quantification.
- The progression of the osteogenic differentiation, in the presence of inflammatory stimuli, was evaluated by measurement of ALP activity and quantification of matrix mineralization.

RESULTS AND DISCUSSION

All stimuli used in this study promoted osteogenic differentiation of hMSCs. This was demonstrated by significantly increased levels of ALP activity and matrix mineralization. ALP levels in the stimulated

cultures were up to three times higher compared to the control condition.

In response to stimulation with LPS, hMSCs significantly up-regulated the gene expression of TLR2 as well as the production of a majority of the cytokines analysed. Bacterial MVs had distinct effects on TLR gene expression and cytokine secretion. The levels of IL-17 and TNF- α were elevated in cultures treated with *S. epidermidis* MVs compared to unstimulated cultures. This stimulation also resulted in an up-regulated gene expression of TLR2 and TLR3 whereas this gene expression was unaffected by *S. aureus* MV-stimulation. However, *S. aureus* MV-stimulation of osteogenic hMSC cultures resulted in increased IL-4 secretion. Over time, a majority of the stimuli, including the osteogenic medium alone, resulted in an increase in IL-2, IL-4, IL-17 and TNF- α .

CONCLUSION

- Pro-inflammatory and immune-triggering molecules can promote the osteogenic differentiation and alter the cytokine secretion of hMSCs *in vitro*.
- Bacterial MVs released from gram-positive bacteria *S. aureus* and *S. epidermidis* promote osteogenic differentiation of hMSCs *in vitro*.
- Bacterial MVs affect the secretion of both pro-inflammatory and immunomodulatory cytokines by hMSCs, indicating that these cells may have a role in host defence processes.

Influence of Sintering Conditions on the Properties of Porous TiO₂ Bone Scaffolds

Katarzyna Reczyńska^{1,2}, Håvard J. Haugen² and Hanna Tiainen^{2*}

¹Department of Biomaterials, AGH University of Science and Technology, Poland

^{2*}Department of Biomaterials, University of Oslo, Norway, hanna.tiainen@odont.uio.no

INTRODUCTION

Microstructure typically has a strong influence on both the mechanical properties of bioceramics and the cell behaviour on their surface. Since the typical sintering process of previously developed TiO₂ scaffolds (20h at 1500°C) results in large and relatively inhomogeneous grain sizes,¹ the objective of this study was to evaluate the influence of different sintering conditions on the grain growth in highly porous TiO₂ bone scaffolds and the impact of the grain size on the material properties and cell behaviour on such scaffolds.

EXPERIMENTAL METHODS

Highly porous TiO₂ scaffolds were produced using polymer sponge replication as previously described.³ Sintering temperature, dwell time, and cooling rate were varied to examine the effect of these parameters on the grain growth and densification of the material. SEM imaging and micro-CT analysis were used to examine the microstructural features of the scaffolds, while the mechanical properties were assessed by compression test. An in vitro cell study using SaOs-2 cell line was performed to evaluate the impact of the altered grain size on the behaviour of osteoblast-like cells on the TiO₂ surface using fluorescent microscopy. Due to the complex 3D structure of the 3D scaffold, TiO₂ discs with three different average grain sizes (small: <5µm, medium: <10µm, and large: <50µm) were prepared using similar TiO₂ slurry and sintering conditions as for the porous scaffolds.

RESULTS AND DISCUSSION

In order to curb the grain growth in TiO₂ scaffolds, multistep sintering was applied in which the sintering is initiated at a temperature favouring after which the densification is completed at a lower temperature. The optimal temperature for initiating the sintering of the ceramic particles was found to be 1350°C, as higher temperatures resulted in exceedingly increased grain growth rate without significant increase in densification, while dwell time of 20h at 1250°C was required to achieve maximum densification of the TiO₂ material.

By multistep sintering the mean grain diameter was reduced tenfold from >50µm of the reference scaffolds sintered 20h at 1500°C to <5µm. Although finer and more uniform grain size generally improves the mechanical properties of ceramic materials, the refined microstructure did not increase the compressive strength of the TiO₂ scaffolds as the average strengths of all scaffold groups prepared by multistep sintering were less than 93% of that of the reference scaffolds. The high compressive strength of the scaffolds sintered for >20h at 1500°C can be attributed to folding of the

strut walls that partially eliminates the triangular void created by the polymer foam template,¹ which could not be achieved during any of the multistep sintering condition applied in this study (Fig 1). This was seen as a slight but not statistically significant increase in closed porosity in the scaffold structure.

Fig.1: Cross-section of the scaffold struts after sintering.

The grain size of the TiO₂ material was also found to influence the cell behaviour of SaOs-2 cultured on TiO₂ discs. A considerably larger number of cells was present on the surface of the TiO₂ discs with large and medium grain sizes in comparison to the smallest tested average grain size at day 3. The cells on these surfaces were also more clustered, while the cells cultured on the small-grained samples tended to only cluster around superficial cracks in the material. In addition to having the highest number of cells at day 7, the cells on the large-grained TiO₂ discs were most clustered and spread on sample surface. This may be related to the distances between the grain boundaries as the cells are likely to use the grain boundaries as anchorage points onto the surface. No statistically significant differences were detected in ALP activity at any on the tested time points between the three different groups (1d, 3d, 7d; *n* = 3).

CONCLUSION

TiO₂ scaffolds with considerably refined microstructure were produced by optimising the sintering conditions. However, the folding and full densification of the strut structure could not be achieved during the multistep sintering, which limits reduction of closed internal porosity within the scaffold, thus reducing the mechanical strength of the scaffold struts. Furthermore, larger grain size appeared to favour the proliferation and spreading of SaOs-2 cells on TiO₂ surface.

Biomaterials for 2D and 3D bio-hybrid robotic devices

Leonardo Ricotti* and Arianna Menciassi

The BioRobotics Institute, Scuola Superiore Sant'Anna, Italy

*Presenting author, e-mail: l.ricotti@sssup.it

INTRODUCTION

Robotics is nowadays facing emerging challenges, due to the need of designing and developing novel machines able to perform complex tasks in non-structured environments and to maintain their functionality for long periods (*e.g.* by self-repairing their structures).

Wet machines and bio-hybrid robotic components recently emerged, opening the way towards the integration of living cells and tissues within artificial devices¹. This approach allows to exploit the unique features of living elements (high efficiency, self-healing capability, glucose-based powering, etc.), although several technological challenges must be faced before achieving this objective^{2,3}.

This work aims at reporting the author's achievements in the field of bio-hybrid systems (mainly concerning bio-hybrid actuation) and at highlighting that 2D and 3D biomaterials are key components of any bio-hybrid machine.

2D BIO-HYBRID ACTUATORS

Actuation has been the most investigated function in the field of bio-hybrid systems, due to the current lack of suitable actuation technologies able to efficiently scale down in dimensions and to reproduce life-like movements in artificial devices⁴.

A possible strategy to build cell-actuated systems is to use 2D biomaterials, to be contracted by muscle activity⁵. Polylactic acid (PLA) ultra-thin films were developed by the authors to this purpose. Such structures were characterized by a high biocompatibility, easy tailorability and high stability (due to the long degradation time, typical of PLA). PLA nanofilms showing a 350 nm thickness were seeded with murine skeletal muscle cells (C2C12 cell line)⁶, achieving a good differentiation, and efficiently contracted by primary cardiomyocytes. Thinner films (down to 50 nm) were also developed by the authors, and coupled with rat cardiac precursors (H9c2 cell line)⁷.

The engineering of muscle cell behaviour on the biomaterial's surface is obviously of primary importance for achieving a functional bio-hybrid actuator. In order to tune surface electrical properties, the authors developed layer-by-layer nanofilms made of poly(sodium-4-sulfonate) (PSS) and poly(allylamine hydrochloride) (PAH). Surface charges were correlated to cell proliferation and differentiation levels⁸. Surface topography was also engineered. The authors fabricated electrospun polyhydroxybutyrate (PHB) scaffolds. The anisotropy of the produced biomaterial allowed an efficient cell alignment, which is a pre-requisite for achieving a bio-hybrid device able to exert a considerable force along one controlled direction⁹.

Recently, the authors demonstrated the synergic effects of a tuned elastic modulus (~ 14 kPa) of the substrate (made of polyacrylamide, PA), an anisotropic

topography and an intracellular stimulation mediated by active nanoparticles. C2C12 cells enhanced their electrical (and consequently their contractile) activity¹⁰.

3D BIO-HYBRID ACTUATORS

A shift towards 3D bio-hybrid actuators would allow to obtain easier-to-handle, usable and powerful machines. However, the need of a vasculature limits this ambitious objective. The recent literature reports some examples of 3D systems, but all of them are limited to small dimensions¹¹.

The authors recently reported the development of a large quasi-3D bio-hybrid system based on the self-assembly (by rolling) of a 2D polydimethylsiloxane membrane, previously seeded with muscle cells¹². The addition of a dedicated pseudo-vasculature to the biomaterials will allow to achieve really 3D functional and long-term stable bio-hybrid actuators.

BIO-HYBRID SENSORS

Bio-hybrid sensors can be fabricated by integrating living cells able to transduce signals and proper reading circuitries. Few examples of bio-hybrid sensors are described in the literature^{13,14}. Most of them do not focus on biomaterials with tuned properties, but only on the transduction mechanism assured by cells. The authors achieved preliminary results (not published) on a bio-hybrid tactile sensor. The use of a proper biomaterial as interface between the cells and the reading system can strongly modulate the signal output, thus opening new possibilities.

CONCLUSION

2D and 3D biomaterials constitute a key element for the development and maintenance of bio-hybrid systems. The combination of different material properties, able to drive cell behaviors towards the required performances, will enable a significant advancement of the bio-hybrid paradigm.

INTRODUCTION

Nanocomposites formed via non-covalent interactions between acidic proteins and metallic ions or inorganic nanoparticles show outstanding structural properties in natural nanocomposite materials such as nacre and bone¹. Therefore, non-covalent interactions have been explored to construct complex, biomimetic materials that mimic the hybrid nanostructure of such natural materials². Herein, we present a novel method to develop an injectable, robust nanocomposite based on reversible bonds between calcium phosphate (CaP) nanoparticles and bisphosphonate-functionalized hyaluronan (HA). CaP nanoparticles and hyaluronan were selected as dispersed matrix composite components due to their biocompatibility and chemical tailorability. Bisphosphonates are known to exhibit an exceptionally strong affinity to the mineral CaP phase in bone. The covalent attachment of bisphosphonate groups to the hyaluronan backbone should facilitate the formation of a hybrid nanocomposite via reversible bonds between polymer-grafted bisphosphonate ligands and CaP nanoparticles.

EXPERIMENTAL METHODS

Materials: Bisphosphonated hyaluronan polymer was prepared via thiol-ene photopolymerization between acrylated pamidronate and thiol-modified hyaluronan. CaP nanoparticles were prepared using a wet-chemical neutralization reaction between calcium hydroxide and phosphoric acid at 60 °C. Physically cross-linked hybrid nanocomposites (HABP•CaP) were prepared by mixing bisphosphonate-modified hyaluronan with suspensions containing CaP nanoparticles. Three types of HA based hydrogels that were chemically cross-linked by means of covalent hydrazone cross-links (HA, HABP, HA+CaP) were prepared as controls.

In vitro characterization: Polymers were analysed by ¹H and ³¹P NMR and CaP nanoparticles were characterized by FTIR, XRD and TEM. HABP•CaP hybrid nanocomposites were investigated using SEM, rheology, and pull-off tests to evaluate mineral adhesion. In addition, swelling and mineralization were tested upon soaking in PBS and/or SBF. (n=3)

In vivo test: Samples were implanted for 4 weeks in bone (femoral condyle defects diameter of 2.85 mm and a depth of 3.0 mm) and subcutaneous tissue (200 µL cylindrical implants) of healthy, skeletally mature male Wistar rats (n=6). Sections were stained using methylene blue and basic fuchsin followed by a qualitative evaluation of the material appearance and tissue response. The new bone formation was quantitative evaluated.

RESULTS AND DISCUSSION

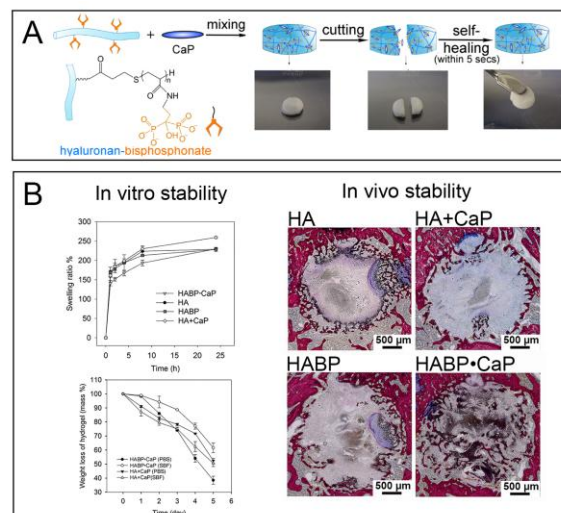

Figure 1A shows that the physically cross-linked hybrid nanocomposite formed by mixing hyaluronan-bisphosphonate with CaP nanoparticles. The hybrid materials displayed rapid (within 5 secs) and pronounced (98%) self-healing behavior. The reversible bonds between bisphosphonate groups and CaP nanoparticles were stronger than other non-covalent interactions. **Figure 1B** shows the stability of the chemically and physically cross-linked formulations in vitro and in vivo. Without the need for additional chemical -and potentially cytotoxic- cross-linking, HABP•CaP nanocomposites were as stable as chemically cross-linked HA hydrogels. Their stability increased under calcium-containing conditions (SBF and bone tissue). It indicated that the reversible bonds between bisphosphonate groups and CaP were sufficiently strong for bone regenerative applications.

CONCLUSION

We have presented a physically cross-linked hybrid nanocomposite, which outperforms conventional, chemically cross-linked analogues in terms of self-healing capacity and adhesiveness to mineral surfaces. Most importantly, these physically cross-linked composites were surprisingly robust yet biodegradable upon extensive in vitro and in vivo testing, thereby confirming that cohesive nanocomposites can be developed based on reversible bonds between polymer-grafted bisphosphonate ligands and calcium ions as present on the surface of nanoscale inorganic particles.

INTRODUCTION

The success rate of dental implant in the maxilla is poorer because quality and quantity of bone in this area is often compromised due to resorption of alveolar crest or pneumatization of the maxillary sinus. Hence, the surgical technique is used to lifting the sinus membrane and creates extra-space for grafting materials to improve the insufficient bone quantity situation in the maxillary posterior area. Autogenous bone is considered the gold standard for grafting the elevated sinus space because of its excellent biocompatibility and bone regeneration potential. However, it still exists some disadvantages¹. Recently, incorporation of osteoinductive agents into the sinus graft materials was focused to accelerate de novo bone formation within the elevated sinus. Our latest research results found that the Ling Zhi-8 (LZ-8) protein can increase wound healing and osteogenic capability^{2,3}. Therefore, the purpose of this study was to develop and evaluate a novel LZ-8 protein-containing porous composite sponge (LZ-PCS) scaffold as the grafting material to elevate the sinus.

EXPERIMENTAL METHODS

The LZ-PCS scaffold was prepared by mixing with 1 mg/ml LZ-8 protein (Yeastern Biotech Co., Ltd., Taiwan), 5 mg/ml collagen, 10 mg/ml methyl cellulose and 15 mg/ml chitosan under -80°C cryogenic freeze drying. The MTT assay (osteoblast cell (MG-63) and fibroblast cell (NIH-3T3)) was employed to test the biocompatibility of the LZ-PCS scaffold. Twelve male New Zealand white rabbits (18–24 weeks, 3.3–3.8 kg) were included in the animal study (approved LAC-100-0053). The control group (TAI YEN Medifil, Taiwan) and LZ-PCS scaffold were inserted in the standardized bony defects (created by 2.5 mm trephine bur) of the nasal bones. The rabbits were sacrificed at 1, 2, 4 and 12 weeks postoperatively. Samples were subjected to histomorphometric examination for evaluating the quantity and quality of the regenerated bone.

RESULTS AND DISCUSSION

In MTT assay, the optical density (OD) values of the control sample increased with increasing the incubation periods when cultured with two different cells. High OD value indicates that the sample possesses a better cell adhesion behavior (i.e. well biocompatibility). As the LZ-PCS sample cultured with the two different cells for 72 h, it still exhibits a high OD value as compared with the control sample. This feature demonstrated that the LZ-PCS scaffold had no influence on the cell

adhesion and proliferation behaviors. The SEM observations of cell morphology of the LZ-PCS sample after culturing for 72 h also indicated that the cells exhibited good adhesion and differentiation. Histological results found that the control sample was largely resorbed at 4 weeks postoperatively (Fig. 1(a)). However, the LZ-PCS sample was filled with newly formed bones in the porous structure (Fig. 1(b)). The new bones of the LZ-PCS sample were found to have the greatest size and density compared with the control sample. The newly formed trabeculae were the smallest in the control group and had the least amount of structure. Flattening of osteoblasts and transformation to osteocytes in the lacunae were observed in the LZ-PCS sample. After 12 weeks surgery, the control sample was completely resorbed. In contrast, the new bone of the LZ-PCS sample cannot be distinguished from the surrounding bone histomorphometrically, which indicated completion of the bone remodeling.

Fig. 1 Histomorphometric examination for the week 4 samples (H&E staining): (a) control group and (b) LZ-PCS group.

CONCLUSION

The LZ-PCS scaffold possesses good biocompatibility and well osteoinductive capability. Therefore, it can be developed as promising biomaterial for biomedical applications.

Phase Constitution and Heat Treatment Behaviour of Ti-Mn-Sn Beta Type Alloys

Masahiko Ikeda^{1*}, Masato Ueda¹ and Mitsuo Niinomi²

^{1*}Department of Chemistry and Materials Engineering, Kansai University, Japan, hikoik@kansai-u.ac.jp

²Institute for Materials Research, Tohoku University, Japan

INTRODUCTION

Titanium and its alloys are suitable to biomaterials because of high specific strength, excellent corrosion resistance and good bio compatibility¹. Unfortunately, those alloys are constituted of rare metallic elements, e.g. molybdenum and niobium. Therefore, those alloys are costly. Users of biomaterials, e.g. medical doctors and patients, do not want to use higher cost biomaterials in all treating parts. Therefore, it is very important to develop reasonable cost metallic biomaterials, especially Ti alloys. To develop low cost Ti alloys as metallic biomaterials, Mn was adopted as beta stabilizing element. Mn is one of abundance metals in earth's crust and one of relatively easily available metals because of alloying materials used in steel making. Sn, which is no toxic for human body, was also adopted as alpha stabilizing element to suppress isothermal omega precipitation. As fundamental study to develop low cost beta type Ti alloy for medical application, phase constitution and heat treatment behaviour of Ti-9mass%Mn-Sn alloys were investigated through electrical resistivity and Vickers hardness measurements and X-ray diffraction.

EXPERIMENTAL METHODS

Ti-9mass%Mn-0, 1, 3 and 5mass%Sn alloys were prepared by laboratory scale arc furnace in high purity argon atmosphere. Obtained ingots were hot-forged and hot-rolled to about 4mm thickness at about 1120K. Specimens were prepared by cutting, grinding and polishing from hot-rolled flat bars. All specimens were solution treated at 1173K for 3.6ks and then quenched into iced water (STQ). Some STQed specimens were isothermally aged at 673K. In STQed and aged specimens, electrical resistivity was measured at room and liquid nitrogen temperatures. Vickers hardness was measured using 4.9N load at room temperature. Phase constitution was identified by X-ray diffraction at room temperature. In STQed specimens, microstructures were observed by optical microscope.

RESULTS AND DISCUSSION

In solution treated and quenched state (STQed state), beta phase was identified and equiaxed beta structures were observed in all specimens. Figure 1 shows changes in electrical resistivity at room and liquid nitrogen temperatures (ρ_{RT} and ρ_{LN}), resistivity ratio of ρ_{LN} to ρ_{RT} (ρ_{LN}/ρ_{RT}) and Vickers hardness (HV) with increase of tin content. Resistivities at both temperatures significantly increased at 1Sn and gradually increased up to 5mass%Sn.

Resistivity ratio significantly increases up to 3Sn and slightly increased at 5Sn. Vickers hardness (HV) decreased up to 3mass%Sn and then increased at 5Sn.

Increase of resistivity is due to dissolution of Sn in Ti. Decrease of HV is due to decrease of athermal omega with increase in Sn content².

Fig. 1 Changes in ρ_{RT} , ρ_{LN} , ρ_{LN}/ρ_{RT} and HV with increase in Sn content.

In isothermal aging at 673K, isothermal omega was identified at aging time between 0.12 and 0.3ks in all alloys. On aging up to 300ks, alpha precipitates were identified in 0, 1 and 3Sn alloy. It is considered that isothermal omega precipitation was suppressed by tin addition. Therefore, aging time at which alpha precipitate was observed is late by tin addition.

CONCLUSION

Results obtained from investigation of phase constitution and aging behaviour of Ti-Mn-Sn alloy are shown as follows. In STQed state, only beta phase was identified in all alloys. Resistivity tends to increase and HV tends to decrease with increase in Sn content. On 673K aging, isothermal omega precipitated and then alpha precipitated.

Hyaluronic Acid Bound Bisphosphonates As A Novel Therapeutic Strategy For Osteoporosis

Sujit Kootala¹, Dmitri Ossipov¹, Xia Yang¹, Yu Zhang¹ and Jöns Hilborn^{1*}
¹Department of Chemistry/Polymer Chemistry, Uppsala University, Sweden
sujit.kootala@kemi.uu.se

INTRODUCTION

Osteoporosis affects nearly 30% of the female population and 20% of the male population worldwide. Clinically, bisphosphonates are commonly used as drugs for the treatment of osteoporosis. However, due to ineffective methods of targeting and delivery, it has been observed that administering the drug orally or intravenously leads to oesophageal cancer, osteonecrosis of the jaw and atypical stress fractures of the long bones. In this study, we demonstrate through an in vitro co-culture model that chemically linking bisphosphonates to biodegradable polymers like hyaluronic acid enhances the specificity of bisphosphonates by targeting osteoclasts and reduces off-target side effects thereby offering better delivery strategies at significantly lower dosages.

EXPERIMENTAL METHODS

Hyaluronic acid (HA) of 7.5 kDa and 150 kDa was purchased from Lifecore (U.S.A) and the fragments were linked to bisphosphonate (BP) groups as described previously (1). RAW 264.7 cells or Peripheral Blood Monocytes (PBMC's) were differentiated on one side of bone discs (Bone Slices, Denmark) according to published procedures for 21 days. MC3T3-E1 cells or Saos cells were cultured on the opposite side of the bone disc and differentiated using previously described procedures[2]. After 21 days of differentiation, the cells washed with 1X PBS and cultured for 24 hours with different doses of neutralized HA-BP in a concentration dependent manner. At 24 hrs, the cells were washed with 1X PBS, fixed with 4% PFA and cells were TRAcP stained for osteoclastic activity. Scanning Electron Microscopy (SEM) was performed post-processing the discs to observe resorption pits. [1].

RESULTS AND DISCUSSION

After the differentiation period of 21 days, the bone discs were processed to identify the extent of mineralization and resorption. Electron microscopy revealed large number of resorption pits with size range between 10µm to 100µm. TRAcP staining for osteoclast activity revealed numerous multinucleated cells. Cells with three or more nuclei were classified as osteoclasts using Image J for analysis. The HA-BP treatment on the 2-sided culture revealed a controlled reduction in the number of osteoclasts compared to discs with osteoclasts alone. The quality of mineralization by osteoblasts and the resorptive activity of the osteoclasts were unaffected in all the conditions, verified by electron microscopy and analysis of the metabolic activity of the cells.

Effects	Co-culture on same side	Co-culture on opposite side
Resorption pits	+++	++
Mineralized nodules	+++	++

Table 1 showing that the co-culture model performed equally or better than the same-sided culture with cells exerting control on each other.

Figure 1. Low molecular weight HA-BP shows high potency towards human osteoclasts on the co-culture model normalized to untreated control and free drug.

Here we demonstrate the potency of etidronate linked to low molecular weight hyaluronic acid against murine and human osteoclasts both in single and two-sided cultures. Osteoblasts and osteoclasts together in two-sided culture result in fewer mature osteoclasts that could be attributed to cellular cross talk via soluble factors.

CONCLUSION

These results encourage the possibility of applying new delivery mechanisms as well as a novel in vitro method to test the effect of soluble drugs like bisphosphonates on bone related cells. This opens up the possibility of testing drugs at a lower dose and provides more useful information on the possible interaction of the drug with the behaviour of two different cell types, therefore moving a step closer to the in vivo scenario

Influence of Anchor Strand Related Parameters on Immobilized Amount and Hybridization Efficiency in a Nucleic Acid-based Immobilization System for Titanium Implants

Cornelia Wolf-Brandstetter¹, Jan Michael², René Beutner¹, Bernd Schwenzer², Henning Schliephake³,
Dieter Scharnweber¹

¹Institute of Materials Science, MBC, TU Dresden, Germany. Cornelia.Wolf-Brandstetter@tu-dresden.de

²Chair of General Biochemistry, TU Dresden, Germany,

³Dept. of Oral and Maxillofacial Surgery, George-Augusta-University, Göttingen, Germany

INTRODUCTION

For further improvement of titanium-based implants a nucleic acid-based immobilization system was developed [1]. The approach involves two steps. The first step is the immobilization of single-stranded nucleic acids (anchor strands = AS) on the implant surface via partial regioselective incorporation into an anodically grown oxide layer (Fig. 1 a,b). The second step, to be done prior to implantation, comprises the hybridization of the anchor strands with complementary strands conjugated with bioactive molecules, selected according to the needs of individual patients (Fig. 1c)¹. Standard γ -sterilization conditions can be applied after the first step. However, strand damages may occur, which are mainly attributed to the formation of reactive oxygen species during anodic polarization and sterilization as well as to the photocatalytic activity of the titanium oxide. Aim of this study was to correlate resistance against strand damage with the AS sequence. Instead of the formerly used AS consisting of 2 identical 30mer hybridization sequences (HS)¹ a newly designed AS (also a 60mer) containing the same HS (30mer) prolonged with a homomeric 30mer spacer based on either poly A, poly T, poly C or poly G was investigated. One of these AS was chosen for further studies referring to impact of anchor strand density to stability of the coating and hybridization efficiency.

EXPERIMENTAL METHODS

The immobilization of the AS was performed on sand-blasted and dual acid etched c.p.Ti discs (KLS Martin) by anodic polarization with 7 - 14 mA/cm² until a voltage of 7.5 V_{Ag/AgCl} was reached. For quantification either the AS or the complementary strand were labelled with ³²P. Hybridization experiments were performed with 3 different strands: a 25mer complementary strand (CS) or a 20mer CS.

RESULTS AND DISCUSSION

Depending on the used AS concentration a surface density of up to 40 pmol/cm² was observed with no significant effect of the strand design. Incubation for 24 h in phosphate buffered saline (PBS) resulted in a loss of ~ 30 - 50% of initially immobilized AS, most pronounced for AS rich in C. Hybridization experiments revealed significant differences depending on the AS's spacer sequence and on the treatment conditions between immobilization and hybridization. In general, higher amounts of CS could be hybridized to AS rich in A. The lowest degree of damage, on the other hand, was observed for AS rich in C especially under conditions with

increased damage by radicals due to prolonged anodization or photocatalytic effects.

Fig. 1: Schematic figure of the immobilization system: a) adsorption of anchor strands on native oxide layer, b) regioselective fixation by anodic oxide growth, c) immobilization of bioactive molecules conjugated to complementary strands, d) release of bioactive molecules by degradation of DNA or direct interaction with target cells.

An increase in anchor strand density for pA resulted for the 25mer CS in increased hybridization efficiency, in particular if the samples were sterilized prior to hybridization. In contrast, hybridization with a 20mer CS resulted in overall higher hybridized amounts but reaching saturation at lower anchor strand density.

CONCLUSION

Our results show that the electrochemical fixation of AS differing only in the design of the spacer region leads to different hybridization behavior with the same complementary strand. The best performance was observed with poly A spacer and can probably be attributed to nucleotide staggering resulting in an elongated shape protruding from the surface and allowing for enhanced hybridization. Further hybridization experiments on immobilized pA imply that in case of the 25mer hybridization occurs via neighbored AS in close vicinity. Improved hybrid stability over several days could be achieved by use of the shorter 20mer CS.

Functional octapeptide hydrogel to bone repair applications

Luis Castillo¹, Alberto Saiani², Julie Gough² and Aline Miller¹

¹Manchester Interdisciplinary Biocentre & The School of Chemical Engineering and Analytical Science

²The School of Materials, The University of Manchester, UK. luis.castillodiaz@prostadgrad.manchester.ac.uk

INTRODUCTION

Bone tissue is frequently damaged by diseases, which generally leads to its degradation, hence the regeneration of bone is currently attracting significant interest¹. The octa-peptide FEFEFKFK, where F is phenylalanine, E glutamic acid and K lysine is known to spontaneously self-assemble into β -sheet rich fibres that self-associate to form a rigid hydrogel when above a critical concentration². Here, the 3D culture of human osteoblasts (HOBs), the mechanical properties and the subsequently production of collagen type I inside FEFEFKFK, RDGFEFEFKFK, and RGDFEFEFKFK gels is explored.

EXPERIMENTAL METHODS

30 mg ml⁻¹ RGDFEFEFKFK, RDGFEFEFKFK (scrambled sequence), and FEFEFKFK hydrogels were prepared. Primary HOBs were grown in DMEM with 10% FBS, and 1% antibiotics, at 5% of CO₂/37°C. LIVE/DEAD, and Picogreen assays were carried out to determinate qualitatively cell viability proliferation respectively. The viscoelastic behaviour of FEFEFKFK gels, was determined using an ARG2 rheometer. ~150 μ L of gel was load onto the bottom plate. The elastic (G') and viscous (G'') moduli as function strain (0.01-100%) at 1 Hz and oscillatory frequency (0.01-100 Hz) at 1% strain. The expression of Collagen I was studied using a standard immunocytochemistry procedure³.

RESULTS AND DISCUSSION

HOBs viability (Figure 1) is similar for the three different gels, where living cells are predominant after 14 days of culture. It is also observed a clear cell spreading inside the RGDFEFEFKFK gel, which might have a positive impact on the attachment and subsequent cell proliferation rate.

Figure 1. LIVE/DEAD assay. Green represents (alive cells), red (death cells). Scale bars = 250

The rate of cell proliferation is higher inside RGDFEFEFKFK gel (Figure 2). This might be favoured by the presence of attachment sites provided for the RGD sequence incorporated along the nanostructure of the gel.

Figure 2. DNA content after two weeks of culture. *** Denotes $p < 0.001$ for comparison of DNA content between the different gels and time intervals.

When the mechanical properties of FEFEFKFK, RDGFEFEFKFK and RGDFEFEFKFK gels were explored, it is clear that G' modulus of the gels with cells, trend to increase the first 7 days under cell culture conditions, however after this time the strength of all gels decreased possibly due to the natural shrink that gels suffer due to the regular exchanges of media (Figure 3). The highest G' modulus values were observed for the FEFEFKFK gel.

Figure 3. Mechanical properties of 3wt% FEFEFKFK, RDGFEFEFKFK, and RGDFEFEFKFK gels. The G' modulus is recorded with and without cells (control), over 14 days.

On the other hand, HOBs were able to produce and deposit collagen type I inside the three different type of gels in a similar rate. This is visually shown by immunocytochemistry images (Figure 4).

Figure 4. Immunocytochemistry representing the production of collagen I (red), and cell cytoskeleton (green) over 14 days of culture. Scale bars = 250 μ m.

CONCLUSIONS

The incorporation of the RGD motif to the FEFEFKFK peptide sequence, improved the cell spreading, attachment and proliferation of HOBs 3D cultured inside the gel during 14 days. The mechanical properties of the gel allowed to the cells not only proliferate even so, to maintain a sustained production of collagen I, which also was clearly deposited inside gels. Thus, the RGDFEFEFKFK system has potential to be used as 3D scaffold to culture HOBs with regenerative applications.

INTRODUCTION

After implantation of polymer-based materials into the body, a cascade of inflammatory host reactions starts, initiating the regeneration of the injured tissue. Besides a myriad of cytokines and growth factors, various cell types play a major role during these different stages of tissue response, like macrophages and endothelial cells. Here, we studied gelatin-based polymer networks with tailorable elastic properties and degradation behavior due to different degrees of crosslinking with lysine diisocyanate ethyl ester. Preliminary experiments revealed good biocompatibility, appropriate cell adhesion and cell infiltration of these hydrogel films depending on their crosslinking degree. Now, investigations on their potential to activate human macrophages and endothelial cells in a pro-inflammatory manner will reveal further insights into biomaterial-cell interactions.

EXPERIMENTAL METHODS

Solutions of 10 wt.-% gelatin were crosslinked with 3- (G10_LNCO3) or 8-fold (G10_LNCO8) excess of isocyanate groups of lysine diisocyanate ethyl ester. Primary human aortic endothelial cells (HAEC) and human leukemia THP-1 cells, differentiated to macrophages (Mφ), were seeded either directly on biomaterial films or cultivated with material eluates in order to simulate hydrolytical or enzymatical degradation *in vivo*. Expression levels of the inducible inflammatory protein cyclooxygenase-2 (COX-2) and its constitutively expressed isoform COX-1, tight junction proteins occludin and claudin-5, and anticoagulant thrombomodulin (TM) were quantified via Western blotting. Additionally, profiles of secreted cytokines and matrix metalloproteases (MMP) were determined using magnetic bead- or color-coded microparticle-based multiplex assays.

RESULTS AND DISCUSSION

In both HAECs and Mφ no influence of hydrolytic or enzymatic eluates on COX-2 expression was observed. In contrast, direct contact to the materials enhanced COX-2 expression, indicating a possible pro-inflammatory reaction. The higher crosslinked material (G10_LNCO8) induced a higher COX-2 expression,

compared to G10_LNCO3. As expected, the expression of COX-1 remained constant (Figure 1).

Figure 1: COX expression in HAEC after contact to hydrolytic (hydr) or enzymatic (enz) material eluates of G10_LNCO3 (CO3) or G10_LNCO8 (CO8), as well as after direct contact to the materials. M: medium control, TPA: inflammation control after treatment with 0.1 μM TPA for 48 h.

The expression of tight junction proteins and TM in HAEC, as well as their cytokine and MMP secretion, were not influenced by the materials, suggesting a maintained endothelial cell function.

In contrast, Mφ altered their cytokine secretion profile after material contact, depending on the crosslinking level of the material.

CONCLUSION

These results point out that direct contact between cells and the hydrogels investigated, but not contact to their hydrolytic or enzymatic degradation products, induced inflammatory reactions in the cells. This indicates an impact of the material surface structure. In general, the materials did not induce endothelial cell dysfunction, whereas macrophages showed inflammatory activation.

INTRODUCTION

Extracellular matrix signals regulate in a complex manner cell behaviour *in vivo* and *in vitro*. We modulate important matrix parameters including 3D topology, mechanics as well as composition and presentation in respect to matrix proteins and glycosaminoglycans (GAG) to dissect their specific impact on macrophage phenotype. We apply defined collagen I-based matrices as well as long-term single cell tracking of the heterogeneous cell populations to reveal the dynamics and fate of macrophages in migration and differentiation. Based on these investigations we envision to reveal fundamental regulating parameters of macrophages function in wound healing.

EXPERIMENTAL METHODS

Immobilized layers (100 - 300 µm) of 3D fibrillar collagen I networks were reconstituted with defined topology and stiffness and functionalized with GAG (hyaluronan, sulfated hyaluronan, heparin). The new automated topological analysis provides quantitative measures (pore size distribution, fibril diameter).¹ Mechanical properties were determined by colloidal probe force spectroscopy. GAG content was quantified by fluorimetry and ELISA. CD14⁺ human monocytes were isolated from peripheral blood and differentiated into inflammatory macrophages by granulocyte macrophage colony-stimulation factor and lipopolysaccharide stimulation. Cell migration and differentiation was analysed within the 3D context of the biomimetic matrices using long-term time-lapse microscopy over 5 days. Our automated single cell tracking analysis revealed in-depth information on migration characteristics of the heterogeneous cell population on single cell level as well as population averages. Differentiation of macrophages was determined by IL10 and IL12 expression using ELISA and immunofluorescence supplemented by morphological analysis for single cell tracking.

RESULTS AND DISCUSSION

Biomimetic 3D collagen I networks could be engineered with a defined topology and mechanics. Pore sizes and Young's moduli were controlled in a

range of 0.5 µm to 5 µm and 10 Pa to 400 Pa. Covalent and non-covalent binding of hyaluronan, sulfated hyaluronan and heparin within the 3D networks provided various GAG presentation modes (immobilized vs. adsorbed) with up to 10% mass content of GAG per collagen I matrix.

Invasion and migration studies of monocyte-derived macrophages indicate distinct characteristics in dependence of matrix parameters. Enhanced invasion and modulated migration type was found for matrices with sulfated GAG. Single cell analysis of migration characteristics further indicated a strong spread of typical migration parameters, which was also reflected in the local expression of differentiation markers IL10 and IL12 determined by immunofluorescence as well as morphology features. These findings suggest a specific impact of matrix topology and GAG functionalization on macrophage characteristics.

CONCLUSION

Our studies demonstrated the advantage of analysing cell behaviour on a single cell level within defined biomimetic matrices *in vitro*. It allows to reveal the impact of topology, mechanics and GAG presentation on macrophage phenotype. Further, it can be concluded that the defined control of matrix parameters as well as single cell characteristics of heterogeneous cell populations is needed to correlate matrix parameters to cell characteristics.

Carbon Monoxide Releasing Nanoparticles

Ryosuke Inubushi, André J. van der Vlies, Hiroshi Uyama and Urara Hasegawa*

Graduate School of Engineering, Osaka University, Japan
r_inubushi@chem.eng.osaka-u.ac.jp

INTRODUCTION

Carbon monoxide (CO), one of the byproducts of heme catabolism via heme oxygenase-1 (HO-1), has recently been recognized as an important signaling mediator in mammals despite its bad reputation as an air pollutant. CO plays versatile roles in tissue protection via anti-inflammatory, anti-proliferative and anti-apoptotic effects. Toward therapeutic application of this gas, several transition metal carbonyls such as $\text{Mn}_2(\text{CO})_{10}$, $[\text{Ru}(\text{CO})_3\text{Cl}]_2$, and $\text{Ru}(\text{CO})_3\text{Cl}(\text{glycinate})$ have been reported as CO donor molecules that release CO under physiological condition.¹ Despite their beneficial effects *in vitro* and *in vivo*, the solubility and toxicity of these molecules remain issue in therapeutic application of this gas. In addition, this kind of small drugs in general has pharmacokinetic problems such as quick clearance from the body and lack of tissue specificity.

To overcome this disadvantage, we previously reported CO-releasing polymeric micelles prepared from triblock copolymers containing ruthenium carbonyl moieties.² The micelles successfully attenuated the inflammatory response in human monocytes and reduced toxicity of the ruthenium carbonyl complex. Although these micelles showed promise in immunotherapy, the complicated preparation limited their practical application.

Here we report novel CO-releasing nanoparticles (CONP). Catechol-bearing CO donors ($\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$) were conjugated to the phenylboronic acid-bearing nanoparticles (PBANP) via reversible covalent linkage. The anti-inflammatory effects of CONP were also assessed.

Figure 1. CO-releasing nanoparticles

EXPERIMENTAL METHODS

$\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$ was prepared by complexing tricarbonyl dichlororuthenium (II) dimer with L-3,4-dihydroxyphenylalanine (L-DOPA). PBANP were prepared by the surfactant-free emulsion polymerization method. The nanoparticles were mixed with $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$ in buffer solution to yield the CONP. The nanoparticles were characterized by dynamic light scattering (DLS) and transmission electron microscopy (TEM). The amount of loaded $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$ was determined by inductively coupled plasma atomic emission spectrometry (ICP-AES). The amount of released CO was determined by using the myoglobin (Mb) assay.³ The anti-

inflammatory effect of the CONP was assessed in murine macrophages RAW 264.7 cells.

RESULTS AND DISCUSSION

The PBANP of 85 nm diameter were loaded with a catechol-bearing CO-donor, $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$, through the reversible covalent linkage between phenylboronic acid and the catechol moiety. Under physiological condition (pH 7.4), the particles showed high loading capacity (0.7 $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$ per phenylboronic acid group). DLS showed that the particle size increased to 188 nm after loading of $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$. The Mb assay revealed that the CONP were capable of releasing 0.8 mol of CO per mol of loaded $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$.

Figure 2. CO release from $\text{Ru}(\text{CO})_3\text{Cl}(\text{L-DOPA})$ and the CONP as a function of time (Mb assay).

Furthermore, the anti-inflammatory effect of the CONP was assessed in RAW264.7 macrophages. Upon the addition of the CONP, the production of inflammatory cytokines and nitric oxide was suppressed in lipopolysaccharide (LPS)-induced inflammation.

CONCLUSION

CONP (188 nm diameter) were successfully prepared. These particles exerted anti-inflammatory effects in murine macrophages. This novel CO-delivery system may show promise for therapeutic applications of CO.

TAGUCHI.Tetsushi@nims.go.jp

INTRODUCTION

Tissue adhesive is a biomedical material that can bond tissues together after surgical operations. It is also applied as a surgical sealant to prevent air or body fluid being released from organs and vascular tissue after the operation. There are three main types of tissue adhesive, however, commercial adhesives still have disadvantages on biocompatibility and bonding strength.

Recently, we have developed a tissue adhesive consisting of human serum albumin and an organic acid-based crosslinker, disuccinimidyl tartaric acid, and reported that this adhesive showed both high bonding strength and good biocompatibility¹. Furthermore, we have shown that tissue adhesives containing hydrophobically modified porcine-derived gelatins showed excellent bonding strength onto fresh vascular media compared with non-modified gelatin^{1,2}. However, porcine-derived gelatin solution with high concentration has low fluidity at room temperature because of its high contents of imino acids such as proline and hydroxyproline and is required to heat to use as a tissue adhesive^{2,3}.

Based on these backgrounds, we have chosen cod-derived gelatins (cGln) instead of porcine-derived gelatin as a base material for surgical adhesives because it has low transition temperature due to its low contents of imino acids including proline and hydroxyproline. We synthesized various hydrophobically modified cGlns (hm-cGln) with different hydrophobic groups and introduction ratios and evaluated their bonding effects on fresh arterial media by combining hm-cGlns with polyethylene glycol-based, four-armed crosslinker (4S-PEG)⁴.

EXPERIMENTAL METHODS

The modification of cGln with hydrophobic groups was carried out using a reaction of active ester of fatty acid chloride or cholesteryl chloroformate with the primary amine of cGln in the presence of triethyl amine. Modification ratio of cGlns with hydrophobic groups was calculated by determination of residual amino group using 2,4,6-trinitrobenzensulfonic acid. The measurement of bonding strength was performed using fresh arterial media as an adherend. The bonding strength was then measured using a Texture Analyzer (TA-XT2i, Stable Micro Systems, Godalming, UK). The hm-cGln concentration was fixed at 40 w/v% and fixed 4S-PEG concentration. After the bonding strength measurement, each sample was fixed with a 10% formalin neutral buffer solution followed by hematoxylin-eosin (HE) staining. Cross sections of the stained samples were observed with an optical microscope (BX51, Olympus, Tokyo, Japan).

RESULTS AND DISCUSSION

Hm-cGlns were successfully synthesized by the method as we reported previously^{2,3} (Figure 1). By changing initial concentrations of fatty acid chlorides or cholesteryl chloroformate, each hm-cGln with three different modification ratios of hydrophobic groups was obtained. The bonding strength of stearyl group modified cGln (Ste-cGln)-based adhesives against fresh arterial media increased with increasing modification ratio up to 9.6 mol% then decreased. This highest bonding strength of Ste-cGln based adhesive was 2-fold higher than that of original cGln (Org-cGln)-based adhesive and 10-fold higher than commercial adhesive. Bonding strength of hm-cGln increased with an increase of alkyl chain length under similar modification ratio. From the observation of HE staining sections after bonding strength measurement, dense adhesive layer was observed on the surface of arterial media, meaning that modified alkyl chains effectively work for the enhancement of interfacial strength between adhesive and arterial media. Also, we clarified that these hm-cGln based adhesives completely degraded within 8 weeks without causing any strong inflammation after the subcutaneous implantation in mice.

These results indicated that the introduction of hydrophobic groups effectively enhanced the interfacial strength between tissue and adhesive.

Fig. 1 Modification of cGln with various hydrophobic groups.

CONCLUSION

Tissue adhesive composed of hydrophobically modified cGln and 4S-PEG group-modified was developed. Resulting adhesive containing Ste-cGln had 10-fold high bonding strength compared with commercial adhesive. Ste-cGln based adhesive degraded within 8 weeks after subcutaneous implantation in mice without causing any inflammation.

INTRODUCTION

Collagen is the main component of the connective tissue extracellular matrix and frequently used for tissue engineering and different biomedical purposes. The main collagen sources are bovine and porcine skin and tendon. However, mammalian collagens potentially carry a risk of transmitting infectious diseases like BSE. Furthermore, bovine and porcine products are rejected in different cultural areas due to religious motives.

Marine animals provide an alternative collagen source without these problems. Jellyfish has a collagen amount of more than 60% of the solid content which is easy to extract. However, a prerequisite for using jellyfish collagen (JC) for biomedical purposes is an examination of its in vivo behaviour regarding biodegradation as well as induction of local and systemic inflammatory and immunological reactions. Therefore, this study aimed at investigating these aspects after implantation of JC matrices into rats.

EXPERIMENTAL METHODS

Preparation of matrices. Fibrillated jellyfish collagen from *Rhopilema spec.* was obtained from CRM GmbH, Kiel, Germany. Matrices were prepared by lyophilization from a 0.5% (w/v) solution and subsequent crosslinking with EDC/NHS. The matrices (JC content: 0.5mg, pore size: 20-200µm) were rigorously washed, stored in phosphate buffer and sterilized by gamma irradiation prior to implantation.

Examination of local tissue response. In a 1st series, one JC sample was implanted into the neck musculature of 24 male Lewis rats. After 7, 14 and 56 days, tissue samples were retrieved from 8 animals respectively. Cryosections were stained with antibodies for total macrophages/monocytes (ED1), tissue macrophages (ED2), total (R73) and activated (OX39) T lymphocytes, antigen-presenting cells (OX6), activated NK cells (ANK61) and nestin (rat-401) using the APAAP method. Cellular reactions were quantified by digital image analysis software ImageJ.

Investigation of systemic immune response. In a 2nd series, five rats received one JC sample implanted into the neck musculature. Additional implantations were performed after 14 and 28 days while the previous implants were removed. Blood was collected pre-OP and weekly post-OP until day 56. Detection of IgG and IgM antibodies against JC was performed using standard ELISA with the antigen (1% w/v) solid-phase coated in 96-well microplates, incubation of rat sera and detection of antigen-bound antibodies with Ig-class-specific anti-rat HRP conjugates.

Statistics. The non-parametric Mann-Whitney test was used for data analysis (GraphPad Prism 4.03).

RESULTS AND DISCUSSION

Biodegradation. In the 1st series, JC samples were still found in tissue of 7/8 animals after 7 days, 4/8 animals after 14 days but none of the 8 animals after 56 days, indicating complete biodegradation within 2 months. However, even in tissue sections with no detectable JC sample, the implant site was always identifiable.

Local tissue reactions. Within the matrices, more ED1-positive M1-type pro-inflammatory macrophages, T lymphocytes, antigen-presenting cells and NK cells were found on day 14 compared to day 7. This increase was probably associated with the biodegradation. On the other hand a concurrent increase of ED2-positive M2-type anti-inflammatory macrophages and nestin expression indicated ongoing tissue regeneration. Inflammatory reactions in the peri-implant tissue were generally not as strong as within the matrices and did not increase significantly from day 7 to day 56 for any cell type. While ED1-positive macrophages around the implants had a moderate non-significant increasing trend, a transient decrease on day 14 was found for T lymphocytes and ED2-positive macrophages.

Humoral response. A broad individual variability in humoral immune response against JC was observed. Regarding anti-JC IgG antibodies, 2/5 animals were positive after the 2nd implantation and 4/5 animals after the 3rd implantation, while 1 animal remained negative throughout the study. Occurrence of anti-JC IgM antibodies was usually short-lived and observed in 2/5 animals after the 1st implantation, in all 5 animals after the 2nd implantation and in 4/5 animals after the 3rd implantation. Anti-JC IgM levels generally increased after each implantation, and 3 animals had a longer-lasting response after the 3rd implantation. Taken together, the anti-JC IgG and IgM response clearly demonstrated a boost effect after repeated implantation.

CONCLUSION

The examined jellyfish collagen samples were completely biodegraded in vivo within 2 months. The local inflammatory response caused by their implantation was strictly confined to the implant site, particularly to the sample matrix, and accompanied by tissue regeneration. Examination of anti-JC IgG and IgM antibodies revealed that a pronounced humoral immune response was only observed after repeated implantation. These results demonstrate the potential of JC for tissue regenerative applications, with further work being required to optimize its in vivo behaviour.

Sulfated Hyaluronan Derivatives Interfere with TGF- β 1 Signalling

V. Hintze¹, A. van der Smissen², S. Samsonov³, L. Huebner¹, S. Rother¹, D. Scharnweber¹, S. Moeller⁴, M. Schnabelrauch⁴, M. T. Pisabarro³, U. Anderegg²

INTRODUCTION

Sulfated hyaluronan (HA) derivatives are promising candidates for functional biomaterials since sulfate groups modulate the binding of growth factors and thereby influence their bioactivity. The interaction of differently sulfated HA derivatives (sHA) with TGF- β 1 in a sulfation dependent manner has previously been described¹. Collagen-based artificial extracellular matrices (aECM) containing sHA have been shown to have several effects on cells relevant in healing processes^{2,3}. In this study the influence of sHA on the binding of TGF- β 1 to its receptors TGF β receptor-I (TGF β R-I) and -II (TGF β R-II) and the resulting biological consequences on growth factor signalling were investigated by *in vitro* cell culture of human dermal fibroblasts (dFb), *in silico* molecular docking and surface plasmon resonance (SPR).

EXPERIMENTAL METHODS

Artificial ECM coatings were produced by *in vitro* fibrillogenesis of collagen-I in the presence of polymeric HA and sHA derivatives. Human dFb were cultured on aECM for 72 h either untreated or with recombinant human TGF- β 1 added to the cell culture medium after cell seeding or in the presence of aECM-adsorbed TGF- β 1 (10 ng ml⁻¹). TGF- β 1 was added to aECM for 2 h at 37°C to enable growth factor adsorption. The supernatant was removed and used for TGF- β 1 quantification by ELISA. After brief washing, wells were used for cell seeding. In an additional experiment dFb were exposed to TGF- β 1, solute non-sulfated HA or sHA as well as pre-incubated combinations of growth factor and HA derivatives. The synthesis of marker proteins for differentiated myofibroblasts (MFb) was analysed on mRNA (qRT-PCR) and protein level (immunofluorescence). The nuclear translocation of the second messengers Smad 2/3 was examined by immunofluorescence. Molecular docking experiments with non-sulfated HA and sHA tetrasaccharides to TGF- β 1 and to the complex TGF- β 1/TGF β R-II were done using Autodock 3 and spatial clustering with the DBSCAN algorithm. SPR analysis was performed with a BIACORE™ T100 instrument, using C1™ sensor chips. TGF- β 1 was pre-incubated with different concentrations of HA or sHA. The preformed complexes were injected over the immobilized TGF β R-I and TGF β R-II, respectively.

RESULTS AND DISCUSSION

Solute and aECM associated sHA prevented TGF- β 1-stimulated α SMA, collagen I (α 1) and ED-A fibronectin expression. Data suggest an impaired TGF- β 1 bioactivity and downstream signalling in the presence

of aECM containing sHA, shown by massively reduced Smad2/3 translocation to the nucleus. *In silico* docking experiments suggest the occupation of the TGF β R-I binding site by sHA, which is supported by SPR experiments. The latter demonstrate that pre-bound sHA prevents binding of TGF- β 1 to TGF β R-I. In addition SPR analysis proved that the binding of TGF- β 1 to TGF β R-II is also impaired by pre-bound sHA.

Fig. 1: Sulfated HA prevents TGF β 1-mediated signal transduction. (A) Molecular docking of non-sulfated HA (red) and sulfated HA (blue) tetrasaccharides on the surface of TGF β 1. The TGF β 1/TGF β R-I/TGF β R-II complex is shown (TGF β 1: yellow, TGF β R-I and -II: dark and light grey); (B) Immunofluorescence staining of dFb cultured with 5 ng ml⁻¹ TGF β 1 or growth factor pre-incubated with 50 μ g ml⁻¹ sHA to analyze nuclear translocation of Smad2/3 (red). Bar 100 μ m.⁴

CONCLUSION

The bioactivity of TGF- β 1 is significantly reduced by sHA. Data suggest that sHA prevents TGF- β 1 signalling by occupying the receptor binding sites and thereby reduces TGF- β 1 driven MFb differentiation.

Vascular network generation in hyaluronic acid by micromolding and photoimmobilization of fibronectin

A. Kömez^{1,4}, E. T. Baran⁴, N. Hasirci^{1,3,4}, V. Hasirci^{1,2,4*}

Departments of ¹Biotechnology, ²Biological Sciences, ³Chemistry, METU, Turkey

⁴BIOMATEN, Center of Excellence in Biomaterials and Tissue Engineering, METU, Turkey, komez.aylin@metu.edu.tr

INTRODUCTION

Microfabrication techniques are used to construct hydrogels with the desired architecture to control cell behavior and formation of tissue. Especially, micromolding and soft lithography are widely applied and easy to use methods.¹ Vascularization is very important for tissue constructs in terms of providing delivery of nutrients and elimination of waste products.² In this study, we aimed to construct microvascular network in methacrylated hyaluronic acid (MeHA) by using micromolding technique and the formed channels were modified with fibronectin by photoimmobilization for restricted area cell attachment.

EXPERIMENTAL METHODS

Micropatterned elastomer mold was obtained by casting and curing of silicone prepolymer on a photoresist (SU-8) coated glass which was developed by UV irradiation through a pattern printed photomask and wet etching. Then, MeHA solution was cast on the mold and crosslinked with UV. Fibronectin in benzoate solution was placed on the patterned gel and activated by exposure to UV through the mask with negative image for immobilization of the fibronectin only in the microchannels (Fig 1).

Figure 1. Micromolding of MeHA with microcapillary network and fibronectin photoimmobilization on the channels for cell attachment and vascularized tissue formation.

Human vascular endothelial cells (HUVEC) were seeded on fibronectin immobilized microchannels and incubated in DMEM medium after cell adhesion. At predetermined time points gels were analyzed under light and confocal microscope for analyzing cellular organization in the microchannel network.

RESULTS AND DISCUSSION

Microchannel network resembling a fractals tree pattern was successfully developed in MeHA gel (Fig 2A). Fibronectin was photo-immobilized on the pattern subsequently for guiding endothelial cells by physical and chemical cues, respectively. Light microscope images (Figs 2B and 2C) showed that cells could selectively adhere on the patterned area and organize on the capillary network.

Figure 2. Image of MeHA hydrogel and HUVEC in microchannel network. (A) MeHA hydrogel, (B) Light microscope images of HUVEC in microchannel network at day 0 and (C) after 7 days of culture. Magnification: X50 (B); X100 (C).

Light reflection (Fig 3A) and confocal (Fig 3B) microscopy showed that cells can be both in elongated and aggregated state in the microchannel space. Confocal examination of the same region further showed that HUVEC adhered into the track of microchannel (Fig 3C) and filled concave space of microchannel (Fig 3D).

Figure 3. Light reflection and confocal images of cultured HUVEC. (A) Light reflection image, (B) and (C) confocal images showing HUVEC in the microchannel, (D) cross section of a channel with HUVEC. Blue and green luminescence show nucleus and actin staining by DAPI and Alexa Fluor-Phalloidin, respectively.

CONCLUSION

MeHA gel can be transformed into a vascular gel construct by microcapillary network patterning and photoimmobilization of fibronectin to study vascularization of tissue engineered constructs.

INTRODUCTION

Myocardial infarction is the leading cause of death worldwide¹. A potential treatment is cardiac tissue engineering which requires a scaffold that would allow cell attachment, spreading, and maintains their differentiation status. In terms of biomaterials, novel materials have been designed. Mimicking the extracellular matrix (ECM) by fibrous structure enhances the cell attachment. In this study we investigated a novel electrospun collagen incorporated fibrous blend of poly(glycerol sebacate) (PGS) and poly(butylene succinate-co-butylene dilinoleate) (PBS-DLA) as a candidate for cardiac tissue engineering.

EXPERIMENTAL METHODS

All materials used in this study were purchased from Sigma-Aldrich if not mentioned elsewhere.

Electrospun Collagen(I)-PGS/PBS-DLA fiber mats were fabricated by dissolving the polymer blend (20 w/v %) in dichloromethane: Methanol (7:3). Electrospinning the polymer solution with the following parameters; working distance of 15 cm, flow rate of 1.6 ml/h and a voltage of 20 V.

Cardiomyocytes (CM) were isolated from 3-days old Sprague Dawley rats as previously described². CM were pre-plated for 2 h, then re-suspended in neonatal CM medium supplemented with 0.5 % horse serum and seeded in a 24-well plate for 5 days at a density of 0.5 million cells/well. Cells were cultured in 5 % CO₂, 95 % air humidified atmosphere at 37°C. Medium was changed every other day. Cell morphology and adhesion were studied via immunocytochemistry. Cells seeded on collagen-PGS/PBS-DLA matrices were fixed with 4 % PFA in PBS for 10 min at room temperature and were permeabilized with 0.1 % Triton x-100 in PBS for 15 min at room temperature. Protein expression of CM namely alpha-actinin (α -Act) was stained with specific antibodies.

RESULTS AND DISCUSSION

The obtained fiber mats had an average thickness of 100 μ m. and fiber diameter of 1.0 ± 0.2 μ m. FTIR analysis (fig. 1) showed the indicative transmission band of collagen type I, the triple-helical structure of amide I and II at 1645, and 2060 cm^{-1} respectively. Morphological studies (Fig. 2) revealed well-developed sarcomere structures in CM on collagen(I)-PGS/PBS fibres after 5 days of culture.

Collagen type I is a natural matrix protein, in order to mimic the myocardium ECM structure and biomolecules we developed a novel electrospun PGS/PBS-DLA blend incorporating collagen type I into the fibres without the need of using highly toxic solvents like 1,1,1,3,3,3-hexafluoro-2-propanol.

Figure 1: ATR-FTIR spectra spectra of collagen-PGS/PBS-DLA (black), neat PGS/PBS-DLA (red) and collagen (I) (blue).

Figure 2: Evaluation of CM cell morphology after 5 days of culture on the indicated matrices, stained for sarcomeric α -Act (CM, red) and DAPI (nuclei, blue). Scale bars: 20 μ m.

CONCLUSION

Newly developed collagen(I)-PGS/PBS-DLA hybrid fibres were successfully fabricated by electrospinning. Immunostaining analyses showed that the hybrid fibres promoted CM adhesion, where CMs exhibited well developed sarcomeric structures comparable to those when grown on fibronectin, the natural matrix protein of CMs. Collagen(I)-PGS/PBS-DLA concludes to be a promising novel functional biomimetic nanofiber for cardiac tissue engineering.

INTRODUCTION:

Scaffold-based vascular tissue engineering aims to regenerate vascular tissue for the replacement of diseased small-calibre blood vessels (diameter < 6mm). Collagen gel is a commonly used scaffold due to its biological properties including a high potential for supporting and guiding vascular cells in the regeneration process¹. The approach we privileged consists in first reproducing the media, which provide the high elastic properties of the vessel wall, thus making it an essential and effective component for blood and nutrients transportation. Starting from an original method, reported previously², for processing collagen and smooth muscle cells (SMCs), the overall goal of this project was to design and develop an endothelialised two layers collagen cell-based scaffold in a disc shape. The underlying layer is composed of fibroblasts (FBs) seeded within collagen. The upper layer is composed of SMCs seeded within collagen and endothelial cells (ECs) are seeded on this construct. This construct is finally expected to provide vascular tissue remodeling due to cells/cells and cells/matrix interactions and to produce an engineered tissue with properties close to that of blood vessel walls. It is also expected to provide a valid in vitro model for further studies of vascular patho-physiology.

MATERIALS AND METHODS:

ECs were isolated by trypsin treatment of human umbilical cords vein (HUVEC) and expanded in HyClone Media M199/EBSS (Fisher). SMCs were isolated from human umbilical cord artery (HUASMC). Initially, the Wharton's jelly that surrounds the arteries was carefully removed by cutting with scissors. The endothelial layer was removed by scraping the artery intima and afterwards, the arteries were cut to rectangle pieces using scissors and finally placed in a Petri dish with M199 medium. After two weeks, the pieces of the artery were removed and the cells were expanded. Aortic adventitial fibroblasts were purchase from LONZA (Walkersville, MD USA).

Type I collagen was extracted from rat-tail tendons and solubilized in acetic acid solution (0.02 N) at a concentration of 4 g/L according to a protocol previously describe³. The collagen solution (2 g/L) was mixed with DMEM and SMCs or FBs (10⁶cells/ml), NaOH (15 mM), and Hepes (20 mM) in deionized water. This mixture was then poured in a specific mold and then let jellify for 30 min at room temperature. Then ECs were seeded on the surface at 10⁵cells/cm² and the construct was incubated at 37°C for 1, 3 or 7 days.

RESULTS AND DISCUSSION

After 24 hrs of growth, the non-circular morphology of endothelial cells shown by immunofluorescence staining (Fig 1A) suggests that the cells are growing and proliferating to form a monolayer on top of the collagen gel layers. The presence of SMCs in the background, inside the gel was confirmed by the 3D confocal image (Fig 1B). Histological staining on transversal section of collagen gels shows the two layers of collagen, one containing SMCs and the others FBs, nested one within the other. After one week of culture, cells density in the gels increased because of gels compaction due to SMCs activities while the ECs layer was shown to remain intact. The alignment of cells due to the specific mold anchoring retaining the compaction in one direction was also observed.

Figure 1: Immunofluorescence staining on (A) top view and (B) 3D confocal image, of cells organization right after 24h of static culture. HUVECs are stained for VE-Cadherin (green), f-actin of HUASMCs with Rhodamin Phalloidin (red) and nuclei with Dapi (blue).

CONCLUSION

Tri-culture of vascular cells were achieved on collagen scaffold without losing endothelial cells. Furthermore, the cells morphologies shown by immunofluorescence staining suggests that cells are making focal attachments. This ongoing experiment shows that it is possible to do vascular cells tri-culture using collagen gel scaffold. The interaction between cells will enhance the matrix remodeling and the properties of the arterial construct. This presentation will show the seeding parameters of all the cells on or in collagen gel. Characterization of cells localization in the collagen matrix will be also shown. Finally, hemocompatibility tests will be performed on this construct.

²Biomedical Engineering/Michigan Technological University, USA, jana.horakova@tul.cz

Small diameter vascular grafts incorporating long term nitric oxide (NO) release were prepared by electrospinning. Polycaprolactone (PCL) was modified by the addition of novel, NO-releasing compounds. An initial burst of NO was measured leading to long term release during 42 days at 37°C in PBS. This demonstrates the presence of NO-releasing groups entrapped within the fibers.

INTRODUCTION

Small diameter vascular grafts (< 6mm) demonstrate poor thrombogenicity and neointimal hyperplasia [1]. To overcome the main cause of failure for these grafts, nitric oxide (NO) release was incorporated in the grafts due to its ability to inhibit platelet activation and smooth muscle cell proliferation [2]. Small diameter vascular grafts were produced by electrospinning. Nanofibers promote cell adhesion and proliferation due to the similarity with the natural extracellular matrix [3]. The incorporation of novel NO-releasing compounds into the fibers brings new potential solutions to the problem of small diameter vascular graft failure. This incorporation of NO release will promote endothelial cell growth and proliferation to encourage the formation of a healthy vascular substitute by preventing thrombosis and neointimal hyperplasia as cells populate the graft.

EXPERIMENTAL METHODS

The custom designed electrospinning setup was used to produce small diameter vascular grafts by collecting fibers on a rotating mandrel. To incorporate NO release into the graft, S-Nitroso-N-acetylpenicillamine particles (SNAP particles) and SNAP-derivatized cyclam were added to the electrospinning polycaprolactone (PCL) solution. NO is released in the presence of catalytically active metals such as Cu^{1+} or reducing equivalents such as ascorbic acid. Therefore, double layered tubes with outer layer containing CuCl_2 were produced. Two single layered tubes (SNAP particles and SNAP-derivatized cyclam) and two double layered samples (SNAP particles- CuCl_2 , SNAP-derivatized cyclam- CuCl_2) were tested for NO release using a Siever's Nitric Oxide Analyzer. One centimeter samples were submerged in PBS to measure evolved NO from the grafts. After an initial burst of NO over 60 minutes, exogenous CuCl_2 and ascorbic acid were added to the PBS solution containing the sample and additional NO release was observed. Samples were immersed in PBS at 37°C and NO release was measured after 3, 10, 21 and 42 days in PBS for 5 minutes followed by the addition of CuCl_2 and ascorbic acid solutions (15 minutes). On the 42nd day, UV light (400 nm) was used to demonstrate continued control of NO release from

the material and determine if there was a further reservoir of NO available.

RESULTS AND DISCUSSION

Scaffolds were 5 cm in length with a 1.65 mm inner diameter. Tubes were cut at 1 cm and NO release was measured. Initially there was high NO flux after putting the tube into PBS solution. After 60 minutes, NO release decreased but when reducing agents were added, additional NO release was observed.

Fig. 1: NO release measured in PBS solution. After 60 minutes, CuCl_2 and ascorbic acid were added to the PBS solution. The blue line depicts NO release of PCL with incorporated SNAP particles, the red line depicts the double layered tube with SNAP particles- CuCl_2 , the green line PCL with SNAP-derivatized cyclam and the orange line the double layered graft with SNAP-derivatized cyclam - CuCl_2 .

After 3, 10, 21 and 42 days, measurement of NO release was carried out showing controlled NO release from the grafts after addition of CuCl_2 and ascorbic acid. After 42 days, the samples were illuminated using UV light to determine if the NO releasing reservoir was totally depleted. In all cases, NO was generated from the fibers upon exposure to UV light after 42 days.

CONCLUSION

Nanofibrous vascular grafts releasing NO were successfully fabricated using electrospinning. Addition of SNAP particles and SNAP-derivatized cyclam to the electrospun PCL fibers resulted in vascular grafts demonstrating long term NO release under physiological conditions. After an initial burst of NO (**Fig.1**), NO-releasing groups are present within the fibers, resulting in long term release. After the addition of physiologically present agents like copper ions and ascorbic acid, an increased NO release was observed after 3, 10, 21 and 42 days of incubation.

INTRODUCTION

Cardiovascular diseases are a leading cause of death. Currently available synthetic grafts are successful at the macrovascular level, but fail at smaller diameters ($\varnothing < 6$ mm) due to thrombogenicity of synthetic materials and compliance mismatches. The aim of this work was to develop an innovative small diameter vascular graft (SFt/gel) composed of an electrospun silk fibroin tubular (SFt) structure, coated by a crosslinked gelatin gel (gel)¹. SFt grafts demonstrated adequate properties as vascular grafts^{2,3}, also with a collagen coating⁴ which however can cause immune responses⁵. Gelatin may evade this problem, still promoting cell adhesion. In addition, our proprietary method for crosslinking gelatin occurs in mild conditions, giving cytocompatible gels with good stability at 37°C¹.

EXPERIMENTAL METHODS

SF tubular (SFt) structures (ID = 6 mm) were obtained by electrospinning on a rotating mandrel, as previously described². Gelatin A (from porcine skin, Sigma) was crosslinked via a Michael-type addition reaction with methylenebisacrylamide (MBA), in aqueous solution¹.

Figure 1: the home-made coating system.

For coating the SFt samples with the gelatin gel a home-made system was designed and fabricated (Fig. 1). SFt samples were mounted on a rotating glass mandrel, dipped in gelatin/MBA water solution and placed in the coating apparatus to complete the crosslinking reaction (50°C, 24h). SEM analyses were performed to investigate the coating homogeneity. Swelling and weight loss behavior were investigated at 37°C up to 25 days in water. Mechanical tensile properties of wet SFt/gel and SFt, used as control, were assessed at 37°C by circumferential, cyclic, creep/recovery, and stress relaxation/recovery tests. From the cyclic tests, compliance values (between 80 and 140 mmHg) of SFt and SFt/gel were obtained. *In vitro* tests were carried out with the L929 murine fibroblast cell line. Indirect cytotoxicity test was performed on the eluates of SFt/gel and SFt samples, by dipping them in DMEM for 1, 3 and 7 days. Direct cytocompatibility test was performed up to 7 days, by investigating cell viability with MTT assay.

RESULTS AND DISCUSSION

Electrospun matrices had a random fibrous structure with an almost uniform fiber size (755 ± 174 nm). SFt/gel structures were successfully obtained with a homogeneous coating of crosslinked gelatin (Fig.2),

which proved stability in water up to 25 days (37°C).

Figure 2: a) macro image of the SFt/gel tubular scaffold; b) SEM image of the cross-section of SFt/gel. Circumferential tensile tests showed higher stiffness (E values) for SFt (1.82 MPa) than SFt/gel (0.58 MPa) structures. Both SFt and SFt/gel proved compliance values similar to that of autografts, and higher than synthetic grafts commonly used (Fig. 3).

Figure 3: compliance values of autologous and synthetic grafts, SFt and SFt/gel structures.

Creep and stress relaxation tests evidenced a higher contribution of the viscous component for SFt/gel compared to SFt. *In vitro* cytotoxicity test revealed no release of cytotoxic substances, and cytocompatibility test showed, at 7 days, a cell viability significantly higher on SFt/gel ($p < 0.05$) than on SFt (Fig. 4).

Figure 4: cytocompatibility test: MTT assay results

CONCLUSION

Novel 6 mm I.D. composite tubular structures were successfully obtained by coating electrospun SF tubes with a homogeneous layer of crosslinked gelatin. SFt/gel mechanical properties, in particular compliance, were similar to clinically used autografts. The gelatin coating was able to improve the biological characteristics of SF.

Design and synthesis of supramolecular biomaterials for *in-situ* cardiovascular tissue engineering

Olga JGM Goor^{1,2*}, Geert C van Almen^{1,2} and Patricia YW Dankers^{1,2}

¹Institute for Complex Molecular Systems and ²Laboratory of Chemical Biology, Department of Biomedical Engineering, Eindhoven University of Technology, P.O. Box 513, 5600 MB Eindhoven, The Netherlands

INTRODUCTION

Cardiovascular and valvular diseases are a major health burden worldwide¹. Although surgical interventions to replace heart valves or arteries provide a significant improve in quality of life, long-term failure of the implants often leads to a decreased life expectancy. To this extent, *in-situ* cardiovascular tissue engineering has evolved as a potential alternative to create instructive, biodegradable scaffolds that aim at using the natural regenerative potential of the human body to engineer a replacement tissue *in vivo*². We aim to synthesize and develop cell-free vascular graft materials, using supramolecular chemistry. These scaffolds are proposed to be indistinguishable from nature with respect to their mechanical and biochemical properties. Tailor-made materials are developed based on supramolecular polymers end-capped with ureido-pyrimidinone (UPy) moieties, able to dimerize upon quadruple hydrogen-bond formation³ providing a dynamic character, spaced with polycaprolactone (PCL) blocks to meet mechanical requirements⁴. Bioactive UPy-modified peptides are incorporated via a modular approach⁵ in order to provide necessary biological signals to attract and stimulate cells inside the scaffold.

METHODS

In the design presented here, we focus on the bioactivation of our materials to endogenously capture cells from the blood into the vascular grafts. More specifically, we aim to immobilize complicated growth factors and proteins onto the scaffold, in particular transforming growth factor beta (TGFβ), which is known to play an important role in the process of EndoMT (endothelial-to-mesenchymal transition)⁶. Via two different supramolecular methods we propose to complex TGFβ onto our surfaces. These approaches are all based on the expansion of our toolbox of UPy-polymers and UPy-peptides in order to gain temporal control at the surface of our biomaterials. Via our traditional approach we bioactivate our surfaces with TGFβ-derived peptides modified with UPy-units. As a new approach, we synthesized UPy-heparin binding peptides that can be incorporated into our UPy-scaffold materials. Upon immobilization of heparin onto the heparin binding peptides, we aim at complexation of TGFβ at the surface via its heparin binding domain.

RESULTS

UPy-functionalized peptides were synthesized using Fmoc protected solid phase peptide synthesis (SPPS). In the traditional approach we successfully synthesized and purified UPy-TGFβ derived peptides based on the LYIDFRKDLG sequence, yielding 72.2 mg (24%). Our heparin approach required the synthesis of UPy-heparin binding peptides, bearing the previously reported heparin binding GLRKKLGA motif⁷, which provided us 74 mg (20%) after purification. Heparin-FITC immobilization onto our supramolecular PCLdiUPy surfaces with 4 mol% incorporation of UPy-heparin binding peptides, showed a 6 fold increase in fluorescence in contrast to the PCLdiUPy control without peptide. In ongoing experiments we aim to immobilize complex proteins that contain a heparin binding domain (e.g. fibronectin) onto the heparin functionalized surfaces and moreover translate this towards *in vitro* cell studies.

CONCLUSION AND DISCUSSION

The two experimental approaches will allow for temporal control at the surface of biomaterials as a next step in the development of supramolecular biomaterials for cardiovascular tissue engineering purposes. Moreover, the strategy presented here to synthesize UPy-based biomaterials with UPy-modified peptides to immobilize full-length growth factor proteins onto these materials can easily be generalized and can also be applied in the field of for example renal regenerative medicine.

INTRODUCTION

Biomaterials can be implanted in not self-healing, i.e. critical size defects, substituting temporarily for the extracellular matrix and assisting the healing process. The material of choice should be degraded in different time frames, depending on the tissue to be replaced, to allow for an optimal ingrowth of cells and support wound healing. Extracellular matrix (ECM) derived materials like gelatin-based hydrogels are degraded under biological conditions and, therefore, are particularly suitable for the regeneration of tissue. However, gelatin-based biomaterials are foreign matter to an organism, which can lead to adverse tissue responses. Using dedicated small animal multimodal imaging the rate of degradation as well as inflammatory responses to biomaterial implantation as important part of the biological evaluation of a biomaterial was studied *in vivo*.

EXPERIMENTAL METHODS

The hydrogels were synthesized by crosslinking a 10 wt.-% aq. gelatin solution using different amounts of ethyl lysine diisocyanate. Two gelatin-based hydrogels with different crosslinking levels (3-fold and 8-fold molar excess of isocyanate groups - G10_LNCO3 and G10_LNCO8) were implanted subcutaneously in immunocompetent SKH-1 mice and degradation was compared. The volume of implanted biomaterial was determined using dedicated 7 T small animal magnetic resonance imaging (MRI) with a specially designed T2 weighted TRARE measuring sequence. The used matrix was 256×128 pixel with a field of view of 4×2 cm. Slice thickness was 0.8 mm. After the measurement a voxel-based evaluation method was applied. Formation of reactive oxygen species (ROS) and induction of cyclooxygenase-2 (COX-2), two markers of pro-inflammatory reactions, were followed by dedicated small animal optical imaging. L-012, a luminol derivative, was used to detect ROS. To visualize the induction of COX-2, a rhodamine coupled indomethacin-based selective COX-2 inhibitor was used. The substances were injected intraperitoneally. Both tracers were preliminary evaluated in SKH-1 mice using a 12-O-tetradecanoylphorbol-13-acetate inflammation model.

RESULTS AND DISCUSSION

G10_LNCO3 and G10_LNCO8 showed different degradation properties. After an initial degradation

period the samples showed significant differences in degradation from day 14 onwards. G10_LNCO3 showed faster degradation compared to the material with the higher crosslinking degree (G10_LNCO8). The less crosslinked material was almost completely degraded ($V < 5\% V_{\text{day 1}}$) after 5 weeks while G10_LNCO8 still remained in the body for at least 8 weeks (Figure 1).

Figure 1: Degradation of gelatin-based hydrogels with different degrees of crosslinking in immunocompetent SKH-1 mice quantified by MRI.

Within the implantation *situs* production of ROS and induction of COX-2 could be observed up to 7 days post implantation around the surgical incision but not within the area of the implant. Onwards no further ROS production and COX-2 induction could be observed.

CONCLUSION

This multimodal imaging study revealed that the crosslinking level of gelatin-based biomaterials determines the degradation time of the material. This allows for targeted modification of the material according to the respective tissue that needs to be replaced. Furthermore, except for minor pro-inflammatory reactions at the incision site, no adverse tissue response could be observed during and after the degradation which is consistent with good biocompatibility of these novel materials.

INTRODUCTION

Nanomedicine is an emerging field of research partly driven by the pressing medical need for effective cancer therapy. Despite a significant level of development, conventional chemotherapy still fails to address the challenges of cancer treatment i.e., achieving high local concentration of the therapeutics at the vicinity of the tumour while minimizing adverse toxic effects on healthy tissues or cells. To overcome these drawbacks, we present a new class of carrier system, termed Quantum Rattles (QR), made of hollow mesoporous silica shells encapsulating two different populations of gold nanostructures - gold nanoclusters (AuNC) and gold nanoparticles (AuNP). AuNC, in particular, have generated a lot of attention thanks to their unique optical and magnetic properties.¹ Their strong photoluminescence, combined with good photostability, large Stokes shift and high emission rate make them good candidates for optical imaging. However, their instability, chemical reactivity and tendency for agglomeration prevent their widespread use since their properties critically depend on their stability.² The QR embodies a breakthrough for the use of AuNC in the biological setting. QR represents a simple, “one-pot” method for the synthesis of AuNC templated by mesoporous silica shells, conferring them stability in biological media. Moreover, the silica shell of the QRs can host a therapeutic payload. Overall, QR is a holistic platform for cancer theranostics, enabling multimodal imaging and combination therapy.

To further our aim in developing QR as injectable drug delivery system (DDS), we report the development of stimuli-responsive drug-delivery carriers based on QR by using the layer-by-layer (LbL) technique. Sequential deposition of thermoresponsive polymers is used to coat the QR. This facilitates effective encapsulation of therapeutics while allowing controlled release of the cargo only upon stimuli when the polymer layers undergo a conformational change caused by a local increase of the temperature, induced by gold nanoparticles-mediated hyperthermia.

EXPERIMENTAL METHODS

Properties of QR: Experimental techniques such as photoluminescence, UV-vis absorption, TEM imaging and size analysis by Dynamic Light Scattering were used to analyse the properties of QR. Cytotoxicity of QR against HeLa cells was evaluated by an MTS assay.

QR as Stimuli-Responsive Drug Delivery Carriers: The build-up of the polymer layers was demonstrated on planar substrates using Quartz Crystal Microbalance (QCM) and on QR using flow cytometry. Release of encapsulated therapeutics was monitored by fluorescence spectrophotometer.

RESULTS AND DISCUSSION

We describe the novel synthesis of QR and analyze QR properties (Figure 1), conferring QR great potential for *in vivo* imaging.

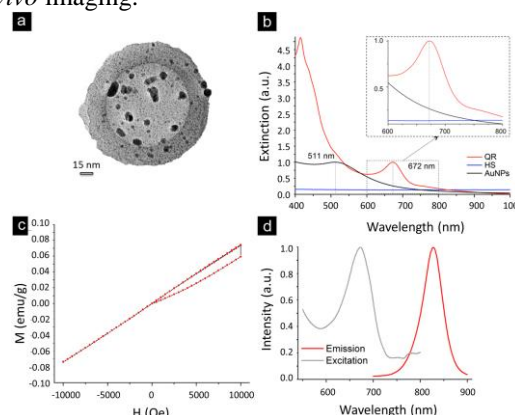

Figure 1: a) TEM image of QR (scale bar is 15 nm). b) UV-Vis absorption spectrum of QR. c) The M vs H magnetisation curves of QR at 2 K showing that QRs exhibit paramagnetic behaviour. d) Photoluminescence excitation (grey) and emission (red) spectra of QR.

We also show the potential of QR for combination therapy *via* both release of anticancer drug and photothermal therapy (PTT). When irradiated by a laser emitting in the NIR, QR generate gold nanoparticle-mediated hyperthermia, and we show the efficacy of QR PTT *in vitro* against HeLa cells.

We develop QR as injectable DDS by showing that coating QR with an optimized lipid bilayer³ promotes the stability of the dispersion at physiological conditions, which is crucial for ensuring a good biodistribution. We further emphasize the use of QR for triggered release of therapeutics, by demonstrating the build-up of thermoresponsive poly[tri(ethylene glycol) methacrylate] (pTEGMA) layers onto these colloidal substrates. The polymer multilayer films assembled on QR are stable at both assembly and physiological conditions as confirmed by flow cytometry. We then investigate the temperature-triggered release of doxorubicin.

CONCLUSION

Quantum Rattle, a novel smart drug delivery system, represents a promising multifunctional platform for cancer treatment, which combines thermally-triggered drug release and gold-mediated hyperthermia.

INTRODUCTION

Superparamagnetic iron oxide nanoparticles (SPION) are of considerable interest as contrast agents due to their nanoscale dimensions, non-toxic nature and magnetic properties. Currently, two SPION are clinically approved, namely: ferumoxides (Feridex in the USA, Endorem in Europe) and ferucarbotran (Resovist). SPION effect is observed mainly on T_2^* relaxation and thus MRI is usually performed using T_2/T_2^* - weighted sequences in which the loss of tissue signal is due to the susceptibility effects of the SPION oxide core. In this study, we aim to develop a novel approach to prepare uniform polymeric particles, by stabilizing iron oxide nanoparticles within dextran nanogels - a class of nanocarriers well suited for numerous specific delivery applications [1]. Nanogels can be formulated by self-assembly of amphiphilic polymers. In such a typical self-assembled formulation, the hydrophobic nanodomains formed within nanogel can be loaded with a variety of therapeutic molecules or imaging agents.

EXPERIMENTAL METHODS

A nanomagnetogel (Figure) that consists on superparamagnetic iron oxide nanoparticles stabilized within hydrophobized-dextran nanogel was produced and characterized regarding physico-chemical (Transmission Electron Microscopy, Cryo-Scanning Electron Microscopy, Dynamic Light Scattering, Small Angle X-ray Scattering), magnetic (relaxometry, MIAplex) and biocompatibility (interaction with cells) properties.

RESULTS AND DISCUSSION

In this study, we have shown that the nanomagnetogel production is simple, reproducible, and exhibit long-term colloidal stability (in water dispersions), at least up to 8 weeks. Our first goal was to explore nanogel loading efficacy, using different nanogel/ γ -Fe₂O₃ ratios and nanogels with different degrees of substitution with alkyl chains (hydrophobic part). The inner structure of the nanomagnetogel was elucidated by combining dynamic light scattering, transmission electron microscopy and small-angle X-ray scattering analysis. The nanomagnetogel has a diameter of around 100 nm and comprises superparamagnetic nanoparticles randomly distributed within the polymer structure. The surrounding corona of dextran allows iron oxide

stabilization avoiding aggregation at physiological pH. The nanogel with the lowest degree of substitution with alkyl chains (NG1) 2.0 mg/mL and 10.0 mM of initial iron concentration was selected as the most interesting formulation, which corresponds to a nanomagnetogel with about 4.0 mM of iron content. Incorporation of iron oxide within the nanogel structure results in promising relaxometric properties, essentially as T_2 contrast agent for MRI [2].

The nanomagnetogel demonstrated non-toxicity for 3T3 fibroblast cultures and was efficiently internalized by bone marrow-derived macrophages, therefore bearing potential as contrast agent for MRI of the organs associated to the reticuloendothelial system (spleen, liver).

CONCLUSION

The nanomagnetogel exhibits r_2 values superior to those of commercially available formulations. The production is simple and easy to scale up, thus offering great technological potential.

INTRODUCTION

Drug-eluting bioresorbable vascular scaffolds are currently changing the landscape of percutaneous coronary intervention (1). The well-known *ABSORB* everolimus-eluting scaffold has struts from poly(L-lactic acid), and its drug-containing surface coating consists of poly(D,L-lactic acid). Bioresorbable vascular scaffolds are clinically successful. Recently, early (< 6 months), late (6-12 months), and very late (> 12 months) angiographic follow-up on 101 patients has shown 6 binary cases of in-segment restenosis, which are due to anatomical or procedural factors. Perhaps the only remaining drawback of these scaffolds is that they are radiolucent. Small platinum markers have to be introduced to visualize the scaffold fluoroscopically, during and after implantation.

We have developed a new contrast agent that can be blended into poly(lactic acid)s without inducing phase separation (2). The additive, (S)-2-hydroxy-3-(4-iodobenzoyloxy) propanoic acid, bears structural resemblance to lactic acid, and also contains covalently bound iodine. Toxicity of the new compound was studied, and found to be comparable with toxicity of L-lactic acid in numerous *in vitro* cell growth assays. We believe that the new contrast agent can be used to manufacture bioresorbable vascular scaffolds with whole-body X-ray visibility.

EXPERIMENTAL METHODS

The new contrast agent was synthesized in 3 steps from Boc-L-serine and 4-iodobenzyl bromide. Purity and identity of the crystalline compound were established by NMR spectroscopy and elemental analysis. Furthermore, the X-ray crystal structure was determined. In the crystal, the molecules are hydrogen bonded to form a one-dimensional chain along the crystallographic a-axis. The contrast agent was blended with a commercial poly(D,L-lactic acid): PURASORB PDL 20 in two ratios: 5 % and 10 % (by mass)., and circular specimens were prepared by hot-pressing. Comparisons were made (e.g., regarding cytotoxicity, hemocompatibility) with blends of PURASORB PDL 20 and Na-ditriazoate (a common X-ray contrast agent).

RESULTS AND DISCUSSION

The blends of the new contrast agent and poly(D,L-lactic acid) showed clear radiopacity (Figure 1). They were transparent materials, whereas the counterpart blends of Na-ditriazoate were white-opaque. This already provided evidence for structural compatibility in the first case, and phase separation in the control blends. This was confirmed by differential calorimetry and X-ray electron spectrometry, which showed homogenous distribution of iodine in the new materials, but not in the blends containing Na-ditriazoate.

Figure 1. X-ray images of 10 stacked aluminium foils (a), two partially overlapping specimens of PURASORB PDL 20 (b), idem of blend 5 % Na-ditriazoate (c) idem of blend 10 % Na-ditriazoate (d), idem of blend 5 % new contrast agent (e), and idem of blend 10 % new contrast agent.

CONCLUSION

The new contrast agent from this study allows, by design, the manufacture of homogeneous radiopaque biodegradable blends of poly(lactic acid)s. Avoiding phase separation is mandatory to achieve control over the degradation kinetics. The concept may be used to manufacture bioresorbable implants with whole-body X-ray fluoroscopy. This is especially relevant for bioresorbable vascular scaffolds. Enhanced fluoroscopic visibility will help to improve accuracy and safety of coronary stenting.

INTRODUCTION

The identification and quantitative grading of early degenerated regions over an entire articular surface remains a challenging quest. However, mechanical testing has proved its efficiency for estimating early degeneration of articular cartilage¹. The objective of this study was to investigate the ability of a novel technique to automatically characterize mechanical properties of entire articular surfaces in indentation in order to rapidly and non-destructively discriminate between damaged and healthy articular cartilage regions.

EXPERIMENTAL METHODS

The distal femurs of eight human tissue donors were obtained and articular lesions were graded with a visual classification system². Mechanical properties were mapped ex vivo, using a novel technique allowing for automated alignment and indentation mapping of articular surfaces. Subsequently, the thickness was measured with an adapted version of the needle technique³. The instantaneous modulus at each position was obtained by fitting the load-displacement curve (with corresponding thickness) to an elastic model in indentation⁴. Osteochondral cores were harvested from visually healthy and osteoarthritis-like regions and tested in unconfined compression where mechanical properties were extracted from the stress relaxation curve⁵.

RESULTS AND DISCUSSION

OA-like regions were identified mechanically and were wider than the regions identified by visual assessment (Blue-green regions in Fig. 1). A strong correlation ($r=0.84$, $p<0.0001$) was observed between the mechanical properties measured in indentation and in unconfined compression (Fig. 2).

Figure 1: Mapping of the instantaneous modulus to identify early OA-like articular cartilage

Figure 2: Significant correlation between the instantaneous modulus and fibril modulus

CONCLUSION

This indentation mapping technique provides fast, efficient and non-destructive measurements of the mechanical properties of the entire articular surface. We also successfully applied this novel technique to mice, rat, rabbit and sheep articular cartilage samples and would be of great use in the identification of wear patterns in osteoarthritis progression and for use in cartilage repair studies.

Introduction: Since the late 90's, medical devices such as meshes are used for the soft tissue reinforcement in the surgical treatment of genital prolapse. One of the major drawbacks of these meshes is their erosion that occurs with time, and the lack of efficient imaging technique to follow erosion and/or motion of the device. As Magnetic Resonance Imaging (MRI) is the gold standard for abdomen and female pelvis imaging¹, we developed MRI visible meshes. The aim of this work was to synthesize a new MRI visible polymer by grafting a MRI contrast agent on the skeleton. The MRI visible polymer can be then coated or integrated into meshes allowing its *in vivo* MR visualization.

Materials and methods: Anionic activation of poly(methyl acrylate) (PMA) chain was performed by removing a proton from the methylene group in α -position of the ester carbonyl, using a non-nucleophilic base². The resulting macropolycarbanion can then react with the electrophile group of an activated DTPA (diethylene triamine pentaacetic acid) leading after hydrogenolysis to a polymer able to chelate Gd^{3+} ions. Grafted polymer was characterized by ¹H NMR and SEC. Coating was characterized by Environmental scanning electron microscope (ESEM). Influence of this MRI-visible polymer cytotoxicity was evaluated *in vitro* on fibroblast cells viability and pro-inflammatory response. MR signal enhancement of the new polymer was investigated on agarose gel using a 7 Teslas experimental MR apparatus compared to a clinical MRI, completed with first MRI visibility tests after prosthesis implantation using an *in vivo* model.

Results and discussion

MR contrast agent (DTPA-Gd) has been covalently grafted on poly (methyl acrylate). The grafted polymer was coated on commercial meshes by spray drying. The coated mesh is clearly detectable *in vitro* by MRI whereas the uncoated mesh remained undetectable. PMA-DTPA-Gd amount used in the coating provides sufficient signal to clearly define the margins of the mesh.

Figure 1 : SEM pictures and Confocal microscopy image of PP meshes compared to PMA and PMA-DTPA-Gd coated meshes after 8 day of incubation with L-929 cells and after live/dead staining. Scale bares represent 100 mm.

Cytocompatibility studies of the grafted polymer on L-929 fibroblasts showed that the DTPA-Gd-PMA coating does not significantly hamper cell adhesion, proliferation or vitality (Fig 1).

To assess the visualization of the coated mesh *in vivo*, two meshes were implanted in the rat's back (intramuscular and subcutaneous). The coated meshes were unambiguously detectable whatever the location (Fig. 2). The structure of the meshes and the limits were significantly detectable, suggesting that the hanging can be easily evaluated.

Figure 2: *In vivo* visualization of two meshes coated with poly(methyl acrylate)-DTPA-Gd implanted in a rat

Conclusion

MR-visible polymer was synthesized and coated on polypropylene-based medical devices. The T1-shortening effect of paramagnetic contrast agent (DTPA-Gd³⁺) grafted onto poly(methylacrylate) was used to visualize meshes for soft tissue reinforcement both *in vitro* and *in vivo*. New polymers covalently linked to contrast agents can easily be coated onto prosthesis (i.e. stent, mesh, suture...) to significantly enhance magnetic resonance signal, allowing a quick MR localization of the device.

S. Aureus Evades Leukocyte Antimicrobial and Mesenchymal Stromal/stem Cell Immunomodulatory Functions

David Antonio Cantu^{1,2}, Warren E. Rose¹, Peiman Hematti³, Weiyuan John Kao (PI, wjkao@wisc.edu)^{1,2,4}

¹School of Pharmacy, ²Department of Biomedical Engineering, ³Department of Medicine, ⁴Department of Surgery, University of Wisconsin-Madison, Madison, WI 53705, USA

Statement of Purpose: Mesenchymal stromal/stem cells (MSCs) intrinsic immunomodulatory activity has been utilized for the treatment of a number of inflammatory conditions and immune disorders¹. In mice cecal ligation models, MSC administration improved subject survival by attenuating excessive inflammation associated with septic shock/multi-organ dysfunction while enhancing phagocytic cell-mediated bacterial clearance in the blood stream^{2,3}. Previously, three-way interactions between encapsulated MSCs, adherent monocytes, and the biomaterial induced up-regulation of the M2 phenotype in monocytes, which was associated with attenuated inflammation and greater phagocytic activity^{4,5}. We hypothesize that MSCs can enhance neutrophil and/or monocyte/macrophage phagocytic function for the elimination of nascent *S. Aureus* biofilms.

Methods: The MBECTTM-HTP device was inoculated with *S. Aureus* (ATCC 29213, 3.0×10^8 CFU/mL) and incubated for either 6 or 24 hrs with continuous rocking (37°C, 10° inclination) to form biofilms. Pins removed from the MBECTTM-HTP device were placed in transwell co-culture containing either monocytes or neutrophils (top chamber) and encapsulated MSCs (bottom chamber) with RPMI 1640 supplemented with either 10% or 1% autologous human serum for 2, 6, or 12 hrs (depicted below) isolated from healthy, primary donors. Planktonic *S. Aureus* was also utilized. MSCs (passages 4 - 6) were encapsulated in either collagen hydrogels or gelatin/poly(ethylene) glycol (Gel-PEG) interpenetrating biomatrices⁶. The *S. Aureus* biofilms or planktonics were sonicated and plated on tryptic soy agar (24 hrs) before counting the observed colonies for Log CFU/mL determination. MSCs, monocytes, or neutrophils were imaged for viability using LIVE/DEAD®.

Figure 1. Transwell co-culture schematic.

Results: Biomatrix-encapsulated MSCs retained high viability for both materials (collagen and Gel-PEG) over various biofilm exposure times, whereas monocyte and neutrophil viability decreased with increasing biofilm

exposure time (2, 6, or 12 hr) or biofilm maturity (6 or 24 hr). A significant decrease in the observed Log CFU/mL was not observed for the various culture conditions with either immune cells (neutrophils or monocytes), co-culture times (2, 6, or 12 hrs), or biofilm maturity (6 or 24 hrs) when compared to the biofilm only condition (with the exception of the minocycline positive control). Similar trends were observed for planktonic *S. Aureus*.

Figure 2. LIVE/DEAD® staining of encapsulated MSCs exposed to nascent biofilm (6 hr); left: [monoculture MSCs (Gel-PEG)]; middle left: [co-culture MSCs (Gel-PEG)]; middle right: [monoculture MSCs (collagen)]; right: [co-culture MSCs (collagen)].

Figure 3. Log CFU/mL tryptic soy agar plating comparison of nascent *S. Aureus* (6 hr) biofilms in 2 hr monoculture or co-culture with neutrophils and/or encapsulated (Gel-PEG or collagen) MSCs (1:1, 1×10^6 cells/mL). Minocycline (2 mg/mL) was utilized as a positive control for bacteriostatic/bactericidal comparison.

Conclusions: Similar to implant-associated infection, *S. Aureus* biofilm and in planktonic form evades leukocyte antimicrobial activities and mesenchymal stromal/stem cell immunomodulatory functions. No direct bacteriocidal activity was observed for MSC.

INTRODUCTION

The management of bone infection remains a significant challenge in orthopaedics and dentistry. The introduction of a biomaterial into the body presents an opportunity for bacterial growth and colonisation which in turn can cause serious medical complications¹. Infections in bone are especially hard to treat due to the difficulty of achieving suitable antibiotic distribution in the infected skeletal tissue². Therefore, there is a great clinical need for bone augmentation materials that are able to encourage bone regeneration whilst possessing antibacterial properties. Nanoscale hydroxyapatite (nHA) pastes have recently been released on the market and early evidence suggests that the bone regeneration capacity of this new class of biomaterials is promising. The addition of silver ions to a nanoscale hydroxyapatite paste may present a novel injectable bone substitute material with antimicrobial activity. The aim of this study was therefore to produce a silver-doped nHA paste and investigate its antibacterial activity.

EXPERIMENTAL METHODS

A wet precipitation method based on Prakash *et al.*³ was used to synthesise a range of silver-doped nHA pastes (0, 2, 5 and 10 mol. %). The silver-doped nHA suspensions were dried in an oven at 60 °C until pastes of approximately 85 % water content were obtained. Complete dehydration of the silver-doped nHA suspensions was also carried out to form powder samples. These were then subjected to a high temperature sintering stage of 1000 °C for 2 h in order to investigate the thermal stability of the products. Characterisation techniques including x-ray diffraction (XRD), attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FTIR) and transmission electron microscopy (TEM) were used to investigate the materials produced. The antibacterial activities of the silver-doped nHA pastes were then tested against *Staphylococcus aureus* and *Pseudomonas aeruginosa* using agar diffusion and broth dilution methods (n=3).

RESULTS AND DISCUSSION

XRD and TEM results displayed the successful formation of nHA in all the samples produced. After heat treatment at 1000 °C, silver-doped nHA samples had an increased tendency to decompose into β -tricalcium phosphate. This suggested that the presence of the silver ions destabilised the nHA crystal lattice.

Fig. 1: Transmission electron microscopy images of 0 (A) and 10 (B) mol. % silver-doped nanoscale hydroxyapatite samples.

The silver-doped pastes had antibacterial activity against *Staphylococcus aureus* and *Pseudomonas aeruginosa*. Due to the inhibition of bacterial growth in the area surrounding the silver-doped pastes, it was suggested that the antibacterial action was due to the presence of diffusible silver ions. Furthermore the antibacterial effect of the silver-doped nHA pastes in a bacterial suspension culture varied in a dose dependent manner. Interestingly, the nHA paste with no silver doping also caused a reduction in bacterial growth when investigated in suspension culture, which may have been due to the adherence of bacteria to the nHA particles.

CONCLUSION

Silver-doped nHA paste with antibacterial properties was successfully produced using a wet precipitation method. It was concluded that silver-doped nHA paste is a promising material for preventing implant associated infection whilst promoting bone tissue regeneration.

Comparisons of the Properties of Linear and Highly-Branded Poly(N-isopropyl acrylamide) with Ligands that Bind Bacteria

P. Teratanatorn, R. Hoskins, J. Shepherd, K. Swindells, T. Swift, L. Swanson, S. MacNeil, I. Douglas, S. Rimmer*
University of Sheffield, UK, s.rimmer@sheffield.ac.uk

INTRODUCTION

Recently we introduced branched polymers that bind to bacteria and then pass through a coil-to-globule transition.¹ The switch from open coil to compact desolvated globule is accompanied by a change from a bacteria non-adhesive state to a bacteria adhesive state. Recent work, which we will describe here, points to a complex model in which the inner regions of the branched polymer are in a desolvated state but the outer regions are solvated in open-coil-like states. Figure 1 shows this model and illustrates the effect of binding, which involves the coil-to-globule transition occurring in the outer regions only.

Figure 1 A Schematic diagramme of a highly branched polymer with ligands at the chain ends interacting with target bacteria. The inner regions of the polymer are desolvated but the outer (shell) segments are aquated a the charged end ligands increase shell swelling. Binding of the end groups by bacteria removes the effect of the end groups causing the desolvation of the shell.

The work presented will compares the performance of hyperbranched poly(N-isopropyl acrylamide) with vancomycin end groups (HB-PNIPAM+van) with different degrees of branching to linear copolymers of poly(N-isopropyl acrylamide) with pendant vancomycin groups (L-PNIPAM+van).

EXPERIMENTAL METHODS

Materials

HB-PNIPAM+van were prepared using our reported procedure.¹ L-PNIPAM+van were prepared by functionalising poly(N-isopropyl acrylamide-co-vinyl benzoic acid) with vancomycin.

RESULTS AND DISCUSSION

Comparisons were made on the performance of highly branched and linear polymers and as shown in figure 2 only highly branched polymers formed mats with *S. aureus*. The mats are formed as aggregates of polymers in the globule form with the bacteria. If the polymers do not form aggregates the bacteria precipitate and form a "button". Examination of polymers of varying degrees branching showed that critical degrees of branching were required to form polymer-bacteria aggregates. By labelling the polymers with fluorescent dyes we have been able to follow the binding of HB-PNIPAM+van and by examining the fluorescence anisotropy we confirmed that a coil-to globule transition does occur on binding.² The HB-PNIPAM+van polymers do not show a cloud point but a transition could be observed in microDSC analysis, which surprisingly was below the ambient temperature.

Figure 2 Images of L-PNIPAM and HB-PNIPAM in the presence and absence of *S.aureus*. The bacteria alone amass at the bottom of the well forming a button. However in the presence of the HB-PNIPAM the interactions between polymer and bacteria forms a mat. On the other hand a linear polymer with penadnt ligands fails to form a mat and the bacteria amass at the bottom of the well in a button.

Also, Nile Red is a dye, whose spectral characteristics are sensitive to the polarity of the environment. The wavelength of maximum absorbance shifts as the environment changes. Addition of this dye to the HB-PNIPAM+van showed that a transition occurred below the temperature of the bacteria binding experiments. Thus the data appeared to be contradictory in that microDSC and the use of Nile red as a probe indicated that the transition occurred below 37 °C but there was no increase in turbidity as would normally be expected in polymers displaying a lower critical solution temperature. On the other hand fluorescence anisotropy indicated that a transition occurred on binding at 37 °C and the mat-button experiments indicated a clear effect of branching.

The data indicated that the branched polymers that respond to binding are not in the fully open coil conformation before binding rather the inner regions of the polymer coil are desolvated but the outer regions are influenced by the chain ends and segments here are solvated in open coil conformation. Binding then causes these outer segments to desolvate producing a surface that bacteria adhere to. The use of Nile Red as a probe also allowed us to provide a quantitative signal of the amount of bacteria present because as the amount of bacteria increases the fluorescence emission intensity increased.

CONCLUSION

HB-PNIPAM+van responds to *S.aureus*. We propose that the performance of the polymers is associated with a coil-to globule transition in the shell of particles.

INTRODUCTION

To conquest the fight against bacteria it is possible to endue a characteristic on biomaterial which has the ability to prevent surface adhesion of bacteria. Various surface coatings for biomaterials have been developed in an attempt to prevent infections; most of them work by incorporating and releasing such bactericidal agents as silver ions, quaternary ammonium salts, triclosan, antibiotics, enzymes or other drugs that leach into the environment¹. Recently, thin film coating based on antimicrobial polymer brushes have gained much popularity owing to the permanent antimicrobial activity. Especially; cationic compounds are promising candidate materials for antibacterial applications.

In this work, PEI molecules covalently grafted to polyurethane (PU) surfaces and then alkylated to increase surface charge². Nanoscale characterization such as topography, roughness, electrostatic potentials, stiffness and surface-bacterial interactions were investigated by force microscopy.

EXPERIMENTAL METHODS

PEI, was covalently grafted onto PU surface and *N*-alkylation was performed by bromohexane. Two different molecular weights of PEI were used to investigate the effect of chain length. The newly obtained surfaces were characterized by Attenuated Total Reflectance – Fourier Transform Infrared Spectroscopy (ATR-FTIR), X-Ray Photoelectron Spectroscopy (XPS) and Scanning Electron Microscopy (SEM). Antibacterial ability of the surface was also investigated by bacterial adherence test.

Topography images of surfaces were obtained by Agilent 5500 AFM (Agilent Technologies, Chandler, AZ) in contact mode under both air and liquid environments and roughness calculations were evaluated by using Gwyddion 2.34 software. Indentation measurements of sample groups were carried out at room temperature with Si₃N₄ AFM tip (Bruker) with 10 pN/nm spring constant. To investigate the electrostatic properties of brush surfaces in aqueous media, Kelvin Probe Force Microscopy (KPFM) technique was applied and contact potential difference (CPD) images were obtained. *E.coli* K-12 (wild type) strain was used to evaluate the single cell – surface interactions. A single cell was attached onto silicon nitride AFM tip. Approximately 60 different force curves were obtained for each sample groups.

RESULTS AND DISCUSSION

Antibacterial surfaces were obtained by PEI grafting onto PU surfaces with following *N*-alkylation. XPS and FTIR data confirmed that PEI grafting and alkylation steps were performed successfully.

Surface roughness in dry state dramatically increases from 65.8 nm to 277.7 nm and 145.2 nm for short and long chained brush-like grafting, respectively; whereas long chained brush-like surfaces exhibit more rough feature than short chained brushes in aqueous media (247.2 nm and 208.7 nm, respectively). AFM images also correlates with aforementioned situation. Since the calculated distances between two grafting points (*D*) were less than radius of gyration (*R_g*) for both long and short chains, it is assumed that the grafted surfaces have brush like characteristics.

The obtained force curves indicated that stiffness and Young's modulus values of the surfaces changes with brush-like layer.

Contact potential difference images obtained from KPFM analysis showed that surface potentials of sample groups exhibit various electrostatic characteristics in aqueous media and increases with *N*-alkylation. Single cell force spectroscopy study results indicate that bacteria-surface interactions are affected by the surface modifications as well.

CONCLUSION

Grafted PEI molecules on PU surface have brush-like conformation and these brush-like structures exhibit an anti-adhesive property against bacteria species via contact-active bactericidal polycationic feature and dynamic chain movement ability.

Effect of pH and biofilm formation on extracellular matrix synthesis in normal and chronic wound fibroblasts

Eleri M Jones¹, Steven Percival², Peter Clegg¹, John A Hunt¹ and Christine A Cochrane¹

¹Institute of Ageing of Chronic Disease, University of Liverpool

²Scapa Healthcare UK Ltd, Manchester, OL7 0ED, elerimj@liverpool.ac.uk

INTRODUCTION

Extracellular matrix (ECM) molecules are synthesised from fibroblast cells as they migrate into the wound space, they play a fundamental role in the process of wound healing and re-modelling. When the wound fails to heal it becomes chronic and the synthesis of ECM molecules becomes impaired. The wound environment changes often becoming infected with bacterial biofilms¹, most commonly *Staphylococcus aureus* and *Pseudomonas aeruginosa*, and the environmental pH becomes increasingly alkaline (pH7-9)².

The aim of this study was to determine any differences in the release of ECM molecules from fibroblasts derived from normal and chronic wound equine tissue when cultured in various environmental pH conditions and with bacterial conditioned media.

EXPERIMENTAL METHODS

Generating different media

The pH of DMEM was altered by addition of concentrated HCl or NaOH with a suitable buffer for that required pH (6 – MES hydrate, 7.5 – HEPES, 9 – CHES). *S. aureus* and *P. aeruginosa* bacteria were cultured in DMEM media overnight before diluting to equivalent of 10⁸ CFU/mL. Bacteria were removed and conditioned media kept for further experiments. *S. aureus* and *P. aeruginosa* biofilms were grown before then being cultured in DMEM media for 24 hours. Media was then collected and filtered and kept for further experiments as biofilm conditioned media.

**this work is on going*

Cell culture

Normal skin fibroblasts (NF, *n*=3) and chronic wound fibroblasts (CWF, *n*=3) were cultured for 24 hours in DMEM media, altered to either pH 6, 7.5 or 9 or in planktonic and biofilm DMEM conditioned media at pH7.5.

Analysing ECM synthesis

Conditioned media (CM) was collected after 24 hours and analysed for the presence of ECM molecules. These were collagen (hydroxyproline assay), fibronectin (FN; ELISA), glycosaminoglycans (GAGs; DMMB assay) and elastin (fastin assay).

RESULTS AND DISCUSSION

Table 1. Summary of the synthesis of ECM molecules analysed when cultured in each condition. Results are shown as an increase/decrease in synthesis compared to normal conditions at pH7.5.

Normal Fibroblasts			
	pH6	pH7.5	pH9
Collagen	↓	-	↑
Fibronectin	↓	-	↓
GAGs	↓	-	↑
Elastin	↓	-	↑
Chronic Wound Fibroblasts			
	pH6	pH7.5	pH9
Collagen	↑	-	↑
Fibronectin	↓	-	↓
GAGs	↑	-	↑
Elastin	↑	-	↓

Changing the environmental culture conditions of both normal and chronic wound fibroblasts affected the synthesis of ECM molecules vital for wound healing. Chronic wound fibroblasts (cultured in pH9 and the presence of biofilms) showed a decrease in the synthesis of collagen, fibronectin and elastin whereas GAGs synthesis significantly increased.

CONCLUSION

An alkaline pH environment, similar to that found in chronic wounds, has negative effects on the synthesis of ECM molecules from CWF cells. Shifting the pH of a chronic wound towards a more acidic environment and eliminating any bacteria present could improve wound healing.

INTRODUCTION

Hydroxyapatite (HA), a calcium phosphate compound, is the major mineral component of bone and is widely used to repair and restrict small or average size bone defect caused by a cancer, a complicated fracture, a malformation, atrophy, or an osteite. It has excellent biocompatibility, bioactivity and osteoconduction properties¹. The HA is used as injectable, granules or macro-porous scaffolds. The risks of recidive associated to a risk of infections (1-2%) lead to dramatic consequences for the patient (new surgery, amputation, etc...). The objective of this work is to develop a chitosan based gel containing a bioactive molecule. This gel could be incorporated in the macro porosity of the scaffold, included with granules in a syringe as injectable material or lyophilised with granules to obtain a new absorbable material.

EXPERIMENTAL METHODS

The hydrogel were prepared by dissolving medium molecular weight chitosan (2%_{w/w}) in an acetic acid solution (1%_{w/w}) containing (2%_{w/w}) of Tween 80. The aqueous solution of genipin (0.5; 0.1; 0.05%) was then added to form a chemical gel. At the end of the process, the gel was freeze-dried (-62°C, 0.06mbar) and stored at room temperature.

The cross linking reaction between genipin and chitosan at 20; 30 and 40°C was followed by UV-spectrophotometry at 376 nm and 604nm. The swelling ratio was determined by placing 20 mg of dried gel in 10mL of water at room temperature. The hydrogel was removed from the water solution at predetermined time and the excess of water on the surface of the hydrogel was absorbed with a soft tissue. The swelling ratio (SR%) was calculated as follow:

$$SR(\%) = \frac{W_s - W_d}{W_d} * 100$$

Where W_s is the hydrogel in the Swollen state, W_d is the weight of the hydrogel in the Dry state.

The cytocompatibility of the hydrogel was evaluated with osteoblasts (MC3T3/E1) according to the ISO 10993-5 standards.

The bioactive molecules (ciprofloxacin/infections and simvastatin/osteogenic effect³) were incorporated in the hydrogel by dissolving in the aqueous genipin solution. The process of gel formation with or without bioactive molecule is the same. The *in vitro* drug release was performed in phosphate buffer saline (PBS) and analyzed by a spectrophotometric method for ciprofloxacin and high-performance liquid Chromatography (HPLC) for simvastatin.

RESULTS AND DISCUSSION

The kinetic of crosslinking reaction between chitosan and genipin showed that the time decreases when the temperature of reaction increases. In the same way, the time of reaction decreases when the concentration of genipin increases. Nevertheless, the evaluation of cell vitality by the method of the Alamar blue showed a low cytocompatibility of the hydrogel crosslinked with a concentration of genipin higher than 0.05%. The best conditions of crosslinking reaction to form a hydrogel of chitosan (2%_{w/w}) with genipin (0.05%_{w/w}) were 40°C during 24 hours. The swelling ability of the hydrogel is an important aspect to evaluate its property, used as scaffold material for tissue engineering or control drug release system. The Figure 1a shows the swelling behaviour of the CHT crosslinking by genipin in distilled water. The swelling rate of hydrogel increases rapidly to reach a plateau value. Indeed, a SR of 320% was obtained after 4 hours in distilled water.

Fig. 1 Kinetic of swelling of hydrogel in distilled water (a); Kinetic of release of ciprofloxacin from hydrogel in PBS (pH 7.4; 80 rpm, 37°C)

The figure 1b shows that the CFX was quickly released from the CHT hydrogel in PBS during the first hour (80%). The prolonged release during the later hours is due to the diffusion process through the hydrogel. The same kinetic was observed with simvastatin. The hydrogel has successfully introduced in the macroporosity of HA (using the pressure of a syringe) or melted with HA granules without modification.

CONCLUSION

We demonstrated the possibility to prepare a cytocompatible chitosan based hydrogel crosslinking with genipin. The promising results could be applied to the prevention of infections or improvement of osteointegration.

Development of Bisphosphonate-functionalized Gelatin Nanoparticles for Application in Colloidal Hydrogels for Bone Regeneration

K. Farbod, J.A. Jansen and S.C.G. Leeuwenburgh*

Department of Biomaterials, Radboud University Medical Center, The Netherlands, kambiz.farbod@radboudumc.nl

INTRODUCTION

An emerging concept in biomaterials research involves the development of colloidal hydrogels, which are cohesive materials made of nanoparticles as building blocks for macroscopic scaffolds¹. Colloidal gels offer several advantages compared to conventional monolithic scaffolds, including a favorable clinical handling behavior, ease of functionalization, cost-effectiveness and capacity to release multiple biomolecules at predetermined rates. Recently, a novel colloidal composite gel made of gelatin and calcium phosphate (CaP) nanoparticles was developed to improve the osteocompatibility of colloidal hydrogels¹. Since bisphosphonate (BP) groups bind strongly to CaP², we hypothesized that noncovalent bonds between CaP and BP-functionalized nanoparticles can be used to develop colloidal gels of improved cohesiveness. Therefore, the current study focused on conjugating BP molecules to gelatin nanoparticles in order to increase the affinity of these organic nanoparticles to CaP. Subsequently, these CaP-binding gelatin nanoparticles were mixed with CaP nanoparticles to investigate the effect of BP functionalization on the viscoelastic properties of the resulting composite colloidal gels.

EXPERIMENTAL METHODS

Using a two-step desolvation method, anionic type B gelatin nanoparticles were prepared as described previously^{1, 3}, which were subsequently functionalized with aminobisphosphonate alendronate (ALN) after glutaraldehyde (GA) crosslinking at various pH values and crosslinking densities. After this crosslinking step, residual aldehyde groups were available for crosslinking with the amine (NH₂) groups of ALN. Morphology and size of the gelatin nanoparticles were characterized in lyophilized and swollen state using Scanning Electron Microscopy (SEM) and cryo-Transmission Electron Microscopy (cryoTEM), respectively. Dynamic Light Scattering was used to characterize the hydrodynamic size and ζ -potential of the gelatin nanoparticles. Inductively Coupled Plasma-Optical Emission Spectrometry (ICP-OES) was used to quantify the degree of bisphosphonation as well as the retention of ALN to the gelatin nanoparticles. CaP nanoparticles were synthesized using a wet-chemical neutralization reaction between calcium hydroxide and phosphoric acid, and characterized using X-ray Diffraction (XRD), Fourier Transform Infrared spectroscopy (FTIR), TEM and cryoTEM. For all the prepared colloidal composite gels, the solid content was 20 w/v% and the gelatin:CaP ratio was 10:1. Storage and loss moduli as well as the extent of self-healing behavior (after destructive shearing at 1000% strain) of

the composite gels were analyzed using oscillatory rheometry.

RESULTS AND DISCUSSION

ICP-OES showed that the efficiency of the conjugation reaction increased with increasing the crosslinking density up to a molar ratio of [GA]:[NH₂]=[2]:[1]. The efficiency of the conjugation reaction was highest at pH 10 and lowest at pH 7, which was attributed to the lack of electrostatic repulsion between nanoparticles at neutral pH, resulting into a low yield. Retention tests showed that up to 70wt% of the initial amount of conjugated ALN was bound to the functionalized nanoparticles after one week of soaking in deionized water. CryoTEM micrographs of highly diluted mixtures of gelatin and CaP nanoparticles showed that interstitial spaces between gelatin nanoparticles were filled with smaller-sized CaP nanoparticles (Fig. 1).

Fig. 1: Cryo-TEM micrographs of CaP and non-bisphosphonated gelatin nanoparticles.

Rheological measurements revealed that colloidal gels consisting of CaP and bisphosphonated gelatin nanoparticles exhibited a lower absolute storage modulus than composite gels consisting of CaP and unmodified gelatin nanoparticles, whereas the extent of self-healing behavior did not significantly change upon bisphosphonation of the gelatin nanoparticles.

CONCLUSION

ALN was successfully conjugated to gelatin nanoparticles through covalent bonding to residual aldehyde groups resulting from nanoparticle crosslinking. Colloidal composite gels consisting of CaP and bisphosphonated gelatin nanoparticles show approximately similar self-healing behavior compared to composite gels consisting of CaP and unmodified gelatin nanoparticles. Future studies will evaluate the self-healing behavior of colloidal composite gels as a function of gelatin:CaP ratio.

INTRODUCTION

Hybrid sol-gel materials have interpenetrating networks of inorganic-organic components that interact at the nanoscale and are indistinguishable above the nanoscale¹. Class II hybrids also contain covalent bonds between silica and polymeric chains and are preferred to Class I hybrids, characterised by weak linkages (e.g. hydrogen bonds). The aim is to achieve a new material where the two components act as a single phase, which has the advantage of enhancing the toughness of inherently brittle bioactive glass scaffolds used in bone tissue engineering. Polycaprolactone (PCL) is a synthetic polyester widely used for biomedical applications because of its total biocompatibility and biodegradability²; however, it lacks functional groups and has very low solubility. Therefore, to be covalently bonded to silica, functionalisation of PCL with a coupling agent before the introduction into the sol-gel process is required. Hybrids made with PCL functionalised with isocyanatopropyl triethoxysilane (ICPTS) were studied, but slow gelation and low mechanical properties limited their applications³. Herein the study of new Class II silica/PCL hybrids using glycidyloxypropyl trimethoxysilane (GPTMS) as coupling agent is described. Final objectives of the present work are: (i) functionalisation of PCL to enable coupling; (ii) optimising the composition for compromise between mechanical properties, biodegradation rate and bioactivity; (iii) tuning the viscosity of the sol to make it suitable for the 3D printing of scaffolds for tissue regeneration.

EXPERIMENTAL METHODS

Hybrid synthesis

SiO₂/PCL hybrids with different compositions were prepared by the introduction into the traditional SiO₂ sol-gel synthesis of PCL diol or triol, using tetraethyl orthosilicate (TEOS) as silica source and GTPMS as coupling agent. In a typical synthesis, PCL was initially functionalised with GPTMS through a two-step procedure: PCL hydroxyl terminal ends were firstly converted into carboxylic groups by oxidation; COOH groups were then covalently bonded to GPTMS epoxy ring ends. Sol-gel was subsequently made by the addition of hydrolysed TEOS into the polymer solution. The sol was then cast into Teflon moulds to obtain bulk cylindrical samples, whereas porous scaffolds were produced by 3D printing directly from the sol. All samples were finally aged at 40°C and dried at 60°C.

Characterisation

PCL functionalisation with GPTMS was assessed through Maldi-Tof, FTIR-ATR and solution-state NMR. Hybrid compositions were assessed through FTIR-ATR, XRD and TGA/DSC analyses. Hybrid

samples were characterised in terms of mechanical properties and *in vitro* biodegradation and bioactivity.

RESULTS AND DISCUSSION

FTIR, Maldi-Tof and ¹H-NMR spectra demonstrated that an almost complete end-capping of PCL OH groups with GPTMS was obtained.

FTIR and XRD analyses on resulting hybrids confirmed the presence of a homogeneous amorphous inorganic/organic hybrid network. Compared to the use of ICPTS as coupling agent, which leads to a gelation time of several days³, the covalent bonding with GPTMS caused faster network formation: gelation occurred within few hours, during which the viscosity of the forming gel can be tuned in order to make it suitable for the 3D printing of scaffolds (Fig.1).

Hybrids with different inorganic/organic ratio, verified from mass loss measured with TGA, were produced in order to evaluate the effect on mechanical properties: the interpenetration of PCL chains within silica network increased the toughness, the hybrids were flexible with elastomeric behaviour (Fig.2), which was more evident when higher polymer percentage was introduced.

Figure 1:
3D printing

Figure 2: Stress-strain curve obtained from compressive test of a monolith.

CONCLUSION

A procedure to covalently couple PCL with GPTMS, exploiting OH groups exhibited by the polymer, was successfully developed. The functionalised PCL was then used for the sol-gel synthesis of innovative Class II SiO₂/PCL hybrids, characterised by an extremely high flexibility. By varying synthesis parameters different features can be achieved, leading to very promising materials for tissue regeneration.

INTRODUCTION

Due to its properties, titanium is the election metal used in implant dental replacement treatment, although total osseointegration process do not finish until 4-6 months after implantation. With the aim to accelerate this process in patient benefit, we developed new formulations of hybrid sol-gel coatings that allow to anchor bioactive molecules to the implant surface and their controlled delivery, providing osteoinductive properties^{1,2}.

EXPERIMENTAL METHODS

Coatings were synthesized by the sol-gel method from specific mixtures of alkoxysilanes methyl trimethoxysilane (MTMOS), tetraethyl orthosilicate (TEOS) and glycidoxypopyl trimethoxysilane (GPTMS). Biocompatibility and osteoinductive capabilities of the coatings were *in vitro* studied with osteoblasts (MC3T3-E1) and *in vivo* through tibia rabbit model of implantation. Histological studies and Si release evaluation were done and light and electron microscopy images were obtained.

After the first *in vitro* and *in vivo* results, gelatine was added to functionalize coatings. *In vitro* and *in vivo* assays were done again with the gelatine containing formulations.

RESULTS AND DISCUSSION

Formulations without gelatine showed a similar cellular behaviour than titanium control, however gelatine containing coatings showed higher mineralization rate.

Figure 3 Gelatine functionalized coatings showed higher ALP activity than control (black) and than non functionalized coatings (red), at 7 (left) and at 14 days (right) of culture (T-Student, significance level 0,005 SPSS 17.0 software).

The histology of the non gelatine containing materials demonstrated that 70MTMOS:30TEOS formulation (7M3T) was totally resorbable at eight weeks, in contrast to the rest of materials in which the coating remained intact. A semiquantitative study showed a

higher biocompatibility behaviour at short times (1 and 2 weeks), than titanium control.

Figure 1 showed at 8 weeks after *in vivo* implantation 7M3T light and electron images, coating (black arrow) was resorbed in new bone contact zones (yellow arrows) and direct contact was observed between bone and implant.

Figure 2 showed at 8 weeks after *in vivo* implantation of the rest of formulations samples, the coatings did not degraded, in contact with it a fibrous capsule was observed (white arrows) making impossible that a direct contact between bone and implant could exist.

No inflammation or infection signs were observed at gelatine coatings after *in vivo* implantation. Histomorphometric study is being carried out and early the statistical results will be available.

CONCLUSION

The *in vitro* and *in vitro* results carry out to expect that the histological results obtained for the last animal implantation of gelatine functionalized 70MTMOS:30TEOS coatings open a very interesting way to enhance osseointegration kinetics.

INTRODUCTION

In order to increase the period of use of implants such as orthopaedic prostheses, the application of coatings made from biocompatible, osteoproliferative materials could support implant incorporation. Also for local drug release purposes, as for middle ear implants, a controlled decomposition behaviour of the coatings is of interest.

In 2010 the osteoproliferative properties of Mg(OH)₂ were investigated by Janning *et al.*¹. The scope of possible applications is limited by the fixed composition of this single compound. Mg-containing Layered Double Hydroxides (Mg-LDHs) are a class of materials with adjustable compositions that can be derived from Mg(OH)₂ by replacing a certain amount of Mg²⁺ ions with trivalent cations such as Al³⁺ and Fe³⁺, leading to Mg-Al- and Mg-Fe-LDHs².

A variety of Mg-LDHs has been synthesized, processed and evaluated with respect to their applicability as implant coatings. Various *in vitro* and *in vivo* studies have been performed, including Mg-LDH based materials with and without drugs (e.g. ciprofloxacin). Different application sites like the middle ear or the condyle of New Zealand White rabbits were in the focus of the studies.

EXPERIMENTAL METHODS

Cell compatibility, osteoproliferative properties and applicability in local drug delivery systems had been in the focus of our earlier *in vitro* and *in vivo* studies.

In our recent *in vivo* study, the degradation behaviour of a Mg-Al-LDH coating in the middle ear of New Zealand White rabbits was investigated. Furthermore, the examination of the degradation rates of different Mg-LDH coatings is in the focus of our recent *in vitro* study.

RESULTS AND DISCUSSION

Mg-Al and Mg-Fe-LDHs were proved to be cell compatible with NIH3T3 and MG63 cells under standard conditions. Cylindrical pellets made from these LDHs (3x3 mm) were inserted into femur condyles of New Zealand White rabbits. According to CT and histological data gained in this *in vivo* study, the Mg-Al-LDH appeared to be the most promising Mg-LDH of our studies with respect to bone-healing purposes.

In another *in vivo* study, middle ear implants were coated with a ciprofloxacin/Mg-Al-LDH mixture and inserted into the middle ears of New Zealand White rabbits. The coatings could release sufficient amounts

of antibiotics to curb an infection that was triggered directly after surgery by *P. aeruginosa*, while the effect was attenuated when the infection was set one week after surgery¹. The controlled release could also be demonstrated in an *in vitro* infection model for over two weeks, employing similar ciprofloxacin/Mg-Al-LDH mixtures.

The *in vivo* stability of LDH coatings in the middle ear was investigated in a subsequent study. Over the time span investigated, the Mg-Al-LDH coatings turned out to be practically stable in the middle ear of New Zealand White rabbits, which opens possibilities for applications with extended functional life times.

In case of some LDHs, storable LDH nanosuspensions could be obtained. Also coating techniques for various substrates were established. For further applications, a spray coating chamber was customized and proved suitable for the semi-automatic spray coating of potential implant materials. This device was used to create samples for our latest *in vitro* study, which showed that different Mg²⁺ release rates can be realized by altering the coating conditions and, as expected, the Mg²⁺ contribution to the coating.

CONCLUSION

Mg-LDHs are a promising class of adjustable biomaterials with regard to the application as implant coatings. Under the experimental conditions the investigated LDHs showed good cell compatibility, osteoproliferative properties and were suitable for local drug delivery. The composition of the respective Mg-LDHs can be varied, i.e. the choice of ions and their ratios, making this class of materials adjustable for different purposes.

Fatigue Characterization of Two Bone Cements Tested Using Various Methods over a Range of *In Vitro* Stress Amplitudes

E.M. Sheafi and K.E. Tanner

School of Engineering, University of Glasgow, Glasgow, UK, e.sheafi.1@research.gla.ac.uk

INTRODUCTION

Inconsistency in results of *in vitro* fatigue testing of bone cements has been reported. One possible reason for this variation is the use of a wide range of testing regimes, with limited consideration to the possible effects of the testing method and stress amplitude on the measured fatigue behaviour of various bone cement compositions. The effect of testing method (moulded or machined surfaces of rectangular or circular specimen shapes), but at only one stress level (± 20 MPa), has previously been examined¹ using two cements and significant variations in fatigue lives were found. An earlier study² considered only the effect of specimen cross sectional shape (produced by moulding), again at one stress level (± 15 MPa), showing longer fatigue lives for the circular specimens of the three cements tested. In terms of considering the effect of stress level, one study³ compared the fatigue behaviour of four bone cements. Fully reversed loading at five stress levels of circular machined specimens was compared to one level stress of tension-tension of rectangular moulded specimens. Significantly less range of differences was reported between the fatigue lives of the cements when the former method was used.

In the current study, the fatigue behaviour of two bone cements was compared over a range of *in vitro* fully reversed tension-compression stress levels. The process was comparably performed for different specimen types, followed by S-N analysis.

EXPERIMENTAL METHODS

Two different bone cement compositions were used: SmartSet GHV Gentamicin (including 2.9wt% ZrO₂ opacifier) and unmedicated DePuy CMW1 (including 6.2wt% BaSO₄ opacifier). Test specimens were manufactured by both direct moulding and machining as rectangular (ISO 527) or circular (ASTM F2118) cross sectional shapes. Four specimen types were produced: rectangular moulded (RDM), rectangular machined (RMM), circular moulded (CDM) and circular machined (CMM), providing four test specimen types. After a minimum of a week soaking in 37°C saline, at least 5 specimens from each category of both cements were tested to failure at each of four fully reversed tension-compression stress amplitudes: ± 12.5 , ± 15 , ± 20 and ± 30 MPa. Cycles to failure for each specimen was recorded and an S-N curve for each specimen testing method was established by plotting the maximum stress levels against the log of cycles to failure. S-N diagrams were produced which compare fatigue behaviour of the two cements in a specific specimen production and shape method.

RESULTS AND DISCUSSION

The S-N diagrams are shown in Figure 1. Each diagram compares the fatigue behaviour of the two cement

compositions for one type of specimen shape and surface finish. Generally, over the tested *in vitro* stress range, the results showed reverse fatigue performance of the two compositions such that SmartSet GHV, in comparison to DePuy CMW1, provided shorter fatigue lives at the highest stress levels and obviously longer lives as the stress amplitude decreased towards the *in vivo* levels. The results, meanwhile, showed differences in fatigue lives among the testing methods which also varied within the individual stress level.

This implies that the fatigue fracture of different cements can perhaps be dissimilarly and even contradictorily controlled by the adopted stress regime starting with the type of specimen used and ending with the stress amplitude allocated.

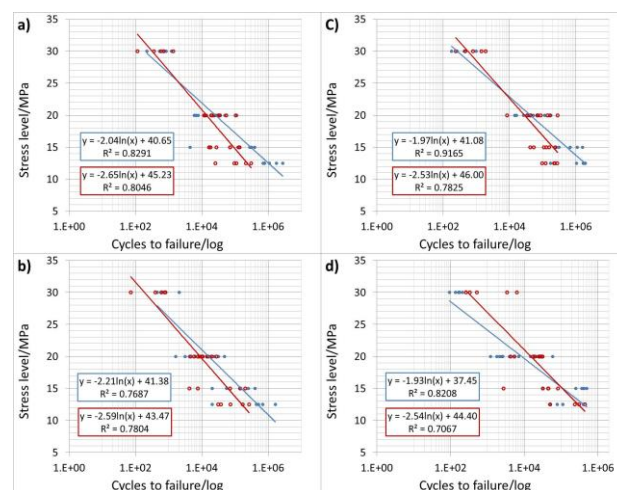

Figure 1 Comparison of S-N curves of SmartSet cement (blue) and DePuy CMW1 cement (red) using testing methods of a) RDM, b) RMM, c) CDM & d) CMM

CONCLUSIONS

Description of fatigue behaviour of bone cements can largely be driven by the selection of the specimen type along with the stress parameters. Thus, when measuring the fatigue life of bone cement, the effect of the stress regime is to be considered, unless an optimal criterion is agreed upon.

roberta.fraioli@upc.edu

INTRODUCTION

Functionalization of the surface with cell adhesive molecules is a straightforward and versatile strategy to confer bioactivity to titanium implants and accelerate osteointegrative processes. Such approach has classically focused on the use of full-length proteins, protein fragments or synthetic oligopeptides derived from the extracellular matrix¹. However, defining which coating system guarantees the best cellular response has been a matter of discussion during the last decade. Peptidomimetics have emerged as a very promising alternative to amino acids based- ligands, due to their high and selective cell-binding activity, low immunogenicity and high stability in serum. In this study, an $\alpha\text{v}\beta 3$ and an $\alpha 5\beta 1$ integrin selective peptidomimetic² (fig. 1) have been covalently anchored to titanium surface, and their ability to promote osteointegration investigated by means of cell adhesion, proliferation and differentiation study of osteoblast-like cells.

Fig 1. $\alpha 5\beta 1$ - (a) and $\alpha\text{v}\beta 3$ - (b) selective peptidomimetics.

EXPERIMENTAL METHODS

Commercially pure (CP) grade 2 titanium disks were polished to obtain mirror-like surfaces ($R_a \approx 40$ nm). Peptidomimetics were covalently immobilized on the surfaces via silanization with 3-(aminopropyl)-triethoxysilane (APTES). Vitronectin (VN) and fibronectin (FN) coated surfaces were selected as positive controls. Contact angle and surface energy measurements, white light interferometry, XPS and fluorescent labeling methods were used to characterize the physicochemical properties of the surface. Osteosarcoma cell line SaOS-2 was chosen to evaluate cell response, by means of adhesion, proliferation and differentiation studies.

RESULTS AND DISCUSSION

The coating strategy was proved effective to attach bioactive mimetics to Ti surface. Moreover, biological activity of the synthetic cues was retained after ultrasonication treatment, proving the mechanical

stability of the coating system. Both peptidomimetics significantly stimulated a positive cell response in terms of adhesion, proliferation and differentiation of SaOS-2 cells compared to uncoated Ti. Interestingly, cytoskeleton organization of cells was particularly enhanced on peptidomimetic functionalized surfaces, and projected area almost reached the one obtained on full-length proteins (fig. 2). Furthermore, peptidomimetics properly supported osteoblastic differentiation, which was assessed by alkaline phosphatase activity and calcified matrix deposition.

Fig 2. Immunofluorescence micrographs of SaOS-2 cells adhering on control Ti surface (a) and peptidomimetic functionalized Ti surface (b), after 4 h of incubation in serum-free medium. (bar = 20 μm)

CONCLUSIONS

The covalent immobilization of integrin-selective peptidomimetics on Ti surfaces was successfully achieved through a simple silanization protocol. The presence of integrin-selective cues significantly stimulated spreading and cytoskeleton organization of SaOS-2 cells. Proliferation and expression of both the early marker of osteoblastic differentiation and the early indicator of mineralized matrix deposition were also up-regulated.

Thus, the strategy reported in this study has proved effective for improving Ti bioactivity and holds great potential for stimulating osteointegration of implant materials *in vivo*.

Impact of Different Sterilization Methods on the Structure, Biodegradation and Cell Response of Collagen Scaffolds Designed for Peripheral Nerve Regeneration

Graziana Monaco^{1,2*}, Rahmat Cholas¹, Luca Salvatore¹, Marta Madaghie¹, Alessandro Sannino¹

¹ Department of Engineering for Innovation, University of Salento, Italy

^{2*} Dhitech Scarl – Distretto Tecnologico High Tech, Lecce, Italy, graziana.monaco@dhitech.it

INTRODUCTION

Cylindrical collagen scaffolds with longitudinal pore orientation have the potential to significantly improve the performance of tubular constructs for peripheral nerve regeneration which are used as alternatives to nerve grafts. The sterilization process is a fundamental step in the fabrication of implantable materials, and the selection of an appropriate sterilization method is critical since materials may undergo chemical and physical alterations that may compromise their structural integrity and functional characteristics¹. Moist heat cannot be used for sterilization of collagen products since autoclaving denatures protein² instead ethylene oxide gassing (EtO) and β irradiation are currently used for sterilising collagen scaffolds¹. As such, the objective of this study is to compare the impact of dry heat sterilization (DHS), EtO gassing and β irradiation on the microstructure, biodegradation and *in vitro* proliferation and infiltration of the rat Schwann cell line RSC96 within collagen scaffolds designed specifically for peripheral nerve regeneration. In this way we want to determine the ideal sterilization method for a novel class III implantable medical device.

EXPERIMENTAL METHODS

Synthesis and sterilization of collagen scaffolds.

Collagen scaffolds with axially oriented pores were fabricated by a freeze-drying procedure, starting from aqueous suspension of Type I collagen, and dehydrothermally and chemically crosslinked. Scaffolds were then sterilized by EtO, β -irradiation, or dry heat.

Scaffold characterization. Morphological evaluation was performed by scanning electron microscopy (SEM). Resistance to enzymatic degradation was evaluated by exposure to collagenase for different incubation times *in vitro*.

Cell response. Scaffolds were seeded with RSC96 and cultured for 6 days. Cytocompatibility and cell infiltration were identified by the MTT assay and histological staining, respectively.

Statistical significance was determined using one-way ANOVA and Fisher's PLSD test.

RESULTS AND DISCUSSION

Morphology. All the scaffolds showed a highly longitudinal oriented pore structure. No major differences in morphology were observed among scaffolds sterilized by the different methods.

Degradation. Preliminary analysis showed accelerated enzymatic degradation of β -sterilized scaffolds compared to EtO-sterilized and non-sterilized controls. This finding is consistent with the literature, which suggests that β sterilized collagen scaffolds may have

an altered biodegradation profile which could potentially affect the tissue regeneration process.

Cytocompatibility and cell infiltration. After 6 days of culture, cell proliferation measured by the MTT assay was not significantly influenced by β sterilisation; whereas, there was a 16% increase in cell proliferation compared to DHS ($p < 0.01$) when cells were seeded on scaffolds sterilized by EtO (Figure 1a). Thus, neither sterilization method resulted in reduced cell viability compared to the control. Cell infiltration, distribution, and morphology within the scaffolds, observed on H&E stained sections, were comparable among the different sterilization groups. In all cases cells were well dispersed throughout the entire scaffold and showed typical morphology (Figure 1b). Therefore, the ability to homogeneously seed the scaffolds with cells was not compromised by the three sterilization methods tested.

Figure 1. Cell proliferation by MTT assay within scaffolds after 6 days culture (a, mean \pm SD, $n=8$); Representative H&E stained section showing a cell-seeded scaffold (b, scale bar 100 μ m).

CONCLUSION

The clinical use of collagen scaffolds requires the selection of a suitable sterilization process, which causes minimal alteration of material properties and avoids the risk of cytotoxic residues. We found that EtO and β treatment did not induce morphological change of the collagen scaffolds, nor did they negatively affect cell proliferation within the scaffolds after 6 days of culture. However, preliminary results indicated an accelerated degradation of β -irradiated scaffolds which could have an effect on scaffold performance *in vivo*. Further characterization of the collagen scaffolds is ongoing in our laboratory to evaluate other parameters which could be affected by sterilization.

INTRODUCTION

The immune cell surface is self-organised into nano- and micro-scale domains of key signalling components that rearrange into more complex architectures on activation,¹ however it is not yet known whether this super-molecular organisation is a requirement, or by-product, of immune cell activation. Here, we fabricate an artificial immune synapse with controlled spatial distribution of key stimulatory ligands on the nanoscale, and use these materials to determine if the nano-scale organisation of stimulatory ligands can be used to control the activation of human immune cells.²

EXPERIMENTAL METHODS

Fabrication of Biofunctionalised Nanoparticle Arrays

Gold nanoparticle arrays were synthesised through Block Copolymer Micellar Lithography (BCML). Specifically, block copolymer PS-b-P2VP was used to generate reverse micelles in solution that were loaded with gold chloride, dip coated onto glass slides, and treated with a hydrogen plasma to generate hexagonally packed gold nanoparticles with uniform order and inter-particle spacing between 10-150nm. Gold nanoarrays were then functionalised with stimulatory ligands, antibodies or antibody fragments to present biomimetic surfaces with immune cell stimulatory ligands positioned precisely on the nanoscale.

Cellular Response to Nanoscale Arrays

Primary human T and NK immune cells were incubated on functionalised biomimetic nanoarrays. Cellular response to altering inter-ligand spacing across the nano-scale regime was measured by comparing the distribution of signalling molecules at the nanopattern-cellular interface region through optical and TIRF microscopy. Individual donor responses were normalised to internal controls. Results were analysed using non-parametric Mann-Whitney comparisons between spacing regimes.

RESULTS AND DISCUSSION

Human CD4⁺ T cells are sensitive to the nanoscale arrangement of stimulatory proteins. Early signalling events, such as phosphotyrosine signalling, decrease significantly as the spacing of stimulatory ligands moves from 25-104nm. Furthermore, when activatory ligands are positioned at 104nm spacing, immune cells fail to respond to biomaterials in an activatory manner (no greater response than adhesive background). The decrease in response between 25-104nm is seen in both adaptive (CD4⁺) and innate (NK) immune cell responses to these stimulatory biomaterials.

Figure 1: Model of nano-scale protein arrays formed by BCML. Image shows a 3D projected Scanning Electron Micrograph of the underlying nanopattern, superimposed with Anti-CD3 F(ab')₂ fragments.

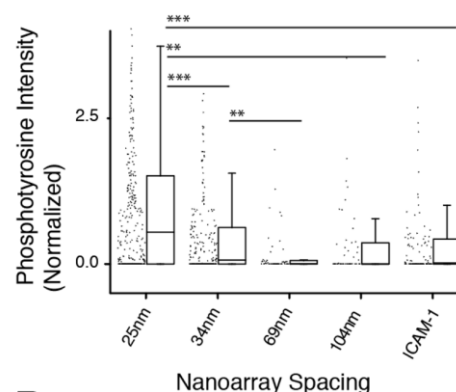

Figure 2: Human CD4⁺ cells were cultured on Anti-CD3 nanoarrays, where the anti-CD3 ligands were anchored at 25, 34, 69 or 104nm. TIRF microscopy was used to measure phosphotyrosine signalling at the nanopattern-cellular interface. p*** < 0.001 p** < 0.01

CONCLUSION

Here, we demonstrate that functionalised gold nanoparticle arrays can be used to form artificial immune synapses. Furthermore, we show that the stimulation of immune cells is sensitive to, and can be controlled by, the nano-scale arrangement of stimulatory ligands at the cellular-material interface, with a sub 110nm inter-ligand spacing being key to activation. This technology offers the potential to direct immunotherapy towards new biomaterials that can controllably activate immune cells.

INTRODUCTION

Medical devices and biomaterial implants are clinically used in a variety of applications, and their performance is critical to a patient's overall health and quality of life. However, biocompatibility remains the key issue to be addressed for an optimal performance of such devices¹. Research is currently focusing on limiting the encapsulation of the device due to chronic inflammation and on increasing the sensitivity and longevity of the implant by enhancing neovascularization². Currently, the most commonly used method to overcome these obstacles is the use of drug releasing implants³. We believe that this paradigm should be reconsidered in view of their limited lifetime.

In the present work, we propose an innovative approach to overcome this pitfall: gold presenting covalently grafted anti-inflammatory or pro-angiogenic molecules. Gold is widely used in medical devices due to its excellent biocompatibility. Applications include wires for pacemakers and gold-plated stents used to inflate and support arteries in the treatment of heart disease, as well as gold-plated myringotomy tubes that are used for implantation in the tympanic membrane.

The objective of this study is to investigate the impact of the anti-inflammatory molecule α -Melanocyte Stimulating Hormone (HS-Ac-SYSMEHFRWGKPV-NH₂ or α -MSH)⁴, as well as the pro-angiogenic peptide sequence GDSVVYGLR⁵ on ameliorating the biocompatibility of gold surfaces.

EXPERIMENTAL METHODS

Biofunctionalization

Our model is based on self-assembled monolayers (SAMs) of thiol-bound carboxyl terminated oligo-ethylene glycol (EO₇-COOH) derivatives on gold. Following this, α -MSH is grafted using a thiol-maleimide bond, thus yielding EO₇-MSH surfaces, while SVVYGLR is coupled by peptide linkage to obtain EO₇-SVV surfaces. Peptide surface density was quantified using PM-IRRAS.

Schematic diagram of the bioactive modified gold surfaces used in this study.

Biological studies

Proliferation was investigated *in vitro* by seeding a small number of Human Umbilical Vein Endothelial Cells (HUVECs) onto our surfaces and by counting

adherent cells after 96h. To discriminate the effect of SVVYGLR from Vascular endothelial Growth Factor (VEGF), experiments were performed with three VEGF concentrations: 0.125%; 0.1% (normal) and 0% VEGF.

We assessed Foreign Body Reaction (FBR) *in vitro* by seeding macrophages onto our surfaces and quantifying their adhesion as well as the formation of multinucleated foreign body giant cells after two weeks.

RESULTS AND DISCUSSION

Surface characterisation

PM-IRRAS confirmed that the EO₇-COOH surfaces are well ordered; tightly packed and can be prepared in a reproducible manner. EO₇-MSH and EO₇-SVV were successfully produced with surface densities of SVVYGLR and α -MSH of 3 and 5 pmol per mm² respectively.

Proliferation

HUVECs proliferated more on the EO₇-SVV surfaces, regardless of VEGF concentration. Importantly, without VEGF stimulation, the surface grafted SVV was able to compensate the absence of stimulation and to still promote proliferation.

Foreign Body Reaction and inflammation

We observed a ten-fold decrease in macrophage adhesion to the EO₇-MSH surfaces when compared to bare gold and EO₇-COOH surfaces. In addition, macrophage fusion did not occur on the EO₇-MSH.

CONCLUSION

Bioactive gold surfaces with controlled surface density were produced and characterized. HUVECs respond to the presence of bioactive molecules by proliferating on surfaces presenting the SVVYGLR peptide. We plan to get a deeper insight into the phenotype of adherent cells by immuno-blotting for the MAP Kinase signaling pathway which is widely implicated in angiogenesis. Regarding FBR, surface bound α -MSH is beneficial in limiting macrophage adhesion. These results have motivated us to test for platelet adhesion and complement activation which are also involved in FBR. We also plan to probe for interleukin-6 expression in HUVECs to quantify their inflammatory response to our surfaces. Future work includes simultaneously modifying gold surfaces with both anti-inflammatory and pro-angiogenic molecules and to test their effect on cell behavior.

INTRODUCTION

Layer by layer (L-b-L) deposition of polyelectrolytes is a versatile technique which has been explored as a smart coating for tissue engineering applications^{1,2}. The most studied film from synthetic polyelectrolytes, such as poly(styrene sulfonate) and poly(allylamine hydrochloride), are relatively stiff and thus favour cell behaviour. Their drawbacks for clinical use are due to the absence of approval by the European medicinal authorities and to potential inflammatory risks. Designing L-b-L using natural polyelectrolytes (polysaccharides or proteins) is then of great interest for medical applications. L-b-L made from Chitosan (CHI) and Hyaluronic Acid (HA) are highly hydrated and often behave as gel-like with a weak stiffness³. Yet, it is generally accepted that cells cannot be easily cultivated on those soft substrates. In this study, we aimed to investigate the effect of HA molecular weight on biocompatibility of CHI/HA multilayer coating.

EXPERIMENTAL METHODS

Hyaluronic acids (HA-1, HA-2 and HA-3 provided by Soliance, France), with 33 500 Da, 363 200 Da and 1.06 MDa molecular weight respectively, were dissolved in NaCl (0.15 M) and used as polyanion. Chitosan (CHI, from Sigma Aldrich) dissolved in HCl (4 mM) was used as polycation. On cleaned cover glasses, CHI was adsorbed for 5 min followed by HA adsorption (contact time of 5 min). Each polyelectrolyte adsorption followed by an extensive NaCl (0.15 M) rinsing step. This process was repeated until the buildup of 15 bilayers film, with an additional terminating layer of CHI.

Stem cells from Wharton's Jelly (WJ-SC) adhesion and proliferation of were highlighted through cytoskeleton visualization and MTS assay respectively.

RESULTS AND DISCUSSION

WJ-SC viability was assessed by MTS assay, following the mitochondrial activity, for 3, 6, and 8 days. CHI/HA films composed of HA-1 and HA-2, *i.e.* Mw < 400 kDa displayed significantly higher cell proliferation compared to corresponding films formed of HA with Mw > 1 MDa. Cells are able to sense their microenvironment and to respond by adjusting the organization of their cytoskeleton, so we highlighted CHI/HA biocompatibility by a complementary approach based on cell spreading *via*

cytoskeleton arrangement. After 15 days of culture, a confluent layer with typical fibroblastic cell shape and with polymerized F-actin fibers was observed on L-b-L made from HA-1 and HA-2 whereas WJ-SC cultivated on L-b-L made from HA-3 remained rounded (Figure 1).

Figure 1: Visualization of cytoskeleton of WJ-SC after 15 days of culture on L-b-L made from CHI and HA named HA-1, HA-2 and HA-3 with 33 500 Da, 363 200 Da and 1.06 MDa respectively molecular weight. The cytoskeleton was visualized by actin filament staining with Phalloidin (green labeling) with Blue nucleus counterstaining of WJ-SC. Objective $\times 63$ Oil.

The Young modulus of the films is under investigation.

CONCLUSION

We demonstrated for the first time, that cell adhesion and proliferation on CHI/HA multilayer film could be improved using HA with MW<400 kDa. Our next step will be to determine the effect of Young modulus of these coatings on their osteogenic potentials.

INTRODUCTION

Among carbon fillers, graphene-based carbon nanomaterials are expected to efficiently reduce wear, simultaneously improving the mechanical properties of UHMWPE composites in artificial joint applications. During the last decade, graphene development has become one of the hottest topics in the fields of material science, physics, chemistry, and nanotechnology. An important objective is to elucidate the interactions between graphene and bioorganism. The reinforcement of UHMWPE with graphene leads to a new family of artificial joints. However, graphene/UHMWPE composites are rarely reported.^{1, 2} Since wear of such graphene/UHMWPE composites can open an entry route of carbon nanoparticles into the body, it is imperative to learn more about the cytotoxicity of graphene. In this study we use aqueous emulsifier-free functionalized graphene (FG)- dispersions (FG-D), derived from thermally reduced graphite oxide (600 m²/g), as model system to examine the effect of FG on the in-vitro cytotoxicity.

EXPERIMENTAL METHODS

The cytocompatibility and the proliferation of different bone markers are assessed using MG 63 cells. Since FG rapidly aggregates when dispersed in the cell culture medium, suspensions of micro-sized FG assemblies (FG-S) are obtained for comparison, thus enabling to understand the role of size, shape and content of FG without changing the FG functionality. FG (0, 0.01, 0.1, 1, 10, and 100 µg/mL), prepared by thermal GO reduction, was diluted with serum free and phenol red free cell culture medium (FG-S) or in water (FG-D).³ WST-1 assay was used to examine cell status of two different dispersion of FG. We also estimated the number of live cells, the proliferations, the protein content, and the ALP- and LDH release. One focus of this study was the effect of FG in different suspensions on maturation of cultured osteoblast (immunohistological investigations: COLI, ON, and AP). To evaluate possible changes in cell morphology induced by graphene ESEM images were obtained. SPSS version 19 for Windows (SPSS Inc., Chicago, USA) was used for graphic presentation and statistical processing of the results.

RESULTS AND DISCUSSION

We report the synthesis, dispersion, and cytotoxicity of FG (600 m²/g), prepared by thermally reducing graphite oxide. As a function of the dispersion process and dispersion medium, it was possible to vary size and shape of FG without changing functionality. While suspension of FG in culture media afforded large

micron-sized FG-assemblies (FG-S), able FG nanosheet dispersions (FG-D) were obtained upon high pressure homogenization in water. It was possible to add FG-D to culture media without encountering FG agglomeration. Determination of cell viability, cell proliferation, cell shape analysis including detection of plasma membrane integrity and osteogenic cell differentiation show a good cytocompatibility of FG, independent of its size, shape, functionality, and surface area. The proliferation of different bone markers is also identical. There is no internalization of FG in osteoblast like cells up to 14 days. FG has a high adsorption capacity of proteins and cells, owing to the presence of functional groups. A high FG concentration of 100 µg/mL can lead to artefacts in biological assays and other investigation methods. To the best of our knowledge, this is the first study that examines the behaviour of osteoblast like cells over a prolonged period of exposure to FG.

CONCLUSION

Our studies have demonstrated that a high specific surface is resulting in a strong interactions of FG with the plasma membrane of cells. This process is not combined with cytotoxic effects up to 10 µg/mL. A concentration of 100 µg/mL can lead to artefacts in biological assays and other investigation methods concerning toxicity because of the very high surface area of TRGO. High protein adsorption followed by strong cell adsorption. This provides strong evidence that FG, independent of its size and shape, is highly cytocompatible below concentration of 100 µg/mL. In conclusion, FG incorporated in UHMWPE affords bearing materials for implants with a high cytocompatibility combined with improved mechanical properties, make them promising material for artificial joints.⁴

INTRODUCTION

In current bone tissue engineering strategies the obtention of sufficient angiogenesis during tissue regeneration is still a major limitation in order to attain construct integration and tissue functionality. This drawback is further relevant when considering large bone defects, where the amount of oxygen required for cell survival is limited to a diffusion distance between 150-200 μm from the supplying blood vessels. Several strategies have been described to tackle this problem, mainly by the use of angiogenic factors or endothelial progenitor cells. However, when facing a clinical scenario these approaches are inherently complex and present a high cost. As such, more cost effective approaches are awaited. We have recently demonstrated that the increased local concentration of calcium (Ca) ions could induce the migration, maturation and organization of endothelial progenitors¹. Moreover, a composite biomaterial of poly(lactic acid) (PLA) and Ca phosphate glass has shown to elicit proangiogenic and chemotactic properties on endothelial precursor cells *in vitro*². Here, we tested electrospun PLA fiber-based materials, containing different ratios of calcium phosphate glass nanoparticles, subcutaneously in mice. These distinct formulations allowing different Ca release kinetics to the vicinity of the matrix expect to improve vessel formation into the biomaterial.

EXPERIMENTAL METHODS

Aligned electrospun PLA nanofibers containing glass ceramic nanoparticles (CaP) at a mass ratio of 0, 10, 20 and 30% (i.e. PLA, NP10, NP20 and NP30, respectively) were prepared as previously described³. One cm diameter membrane disks were cut and sterilized by UV. The biomaterials were implanted subcutaneously in the dorsal pouch of swiss strain female mice (3 month, n=6 for each material). At 1 and 4 weeks post implantation animals were sacrificed and materials, together with the surrounding tissue, were recovered. Samples were fixed in 4% paraformaldehyde for 24 hrs at 4°C and then processed for cryosection. Sequential 8 μm sections were performed; samples were then processed for HE staining or immunohistochemistry for CD31. The same implantation procedure was equally performed for 3 weeks of implantation, samples were recovered, snap frozen and homogenized for total protein extraction. A dot blot array of angiogenic factors (Abcam) was used to assess the different composites. Using the Graphpad Prism 5.0 software, statistically significant differences between several groups were analyzed by the non-parametric Kruskal-Wallis test, followed by a Dunns post-test. A $p < 0.05$ was considered to be statistically significant.

RESULTS AND DISCUSSION

All constructs tested showed augmented cellular penetration with increased time of implantation. An increase on microvessel formation was observed in the case of the constructs containing glass ceramic nanoparticles, when compared with PLA alone, at both 1 and 3 weeks post implantation (see figure 1).

Figure 1- Evaluation of the number of vessels present inside the biomaterial (i.e. PLA, and PLA containing 10, 20 and 30% (w/w%) CaP nps) upon 1 and 4 weeks of subcutaneous implantation (Aver \pm SD, * and ** denote significant differences from PLA alone, with $p < 0.05$ and 0.025 , respectively, $n = 6$).

Additionally, this effect was shown to correlate with their mass ratio and their Ca release profile. Angiogenic factor array assessment, at 3 weeks post implantation, revealed an increased expression of key pro-angiogenic and chemotactic factors for the 20% composite materials in comparison with PLA alone or sham-operated animals. Further studies are being performed to clarify the *in vivo* mechanism for improved angiogenesis. Additionally, the evaluation of selected materials in a bone orthotopic site in a rat critical size defect model is underway and will shed light on the impact in bone regeneration strategies.

CONCLUSION

The developed composite materials have the ability, *in vivo*, to increase the vessel formation into the implanted structures. This approach, due to its simplicity, presents an attractive strategy for clinical musculoskeletal repair.

INTRODUCTION

Non-viral gene carrier plays an important role in gene delivery for gene therapy. Polyethyleneimine (PEI), which is regarded as the “golden” standard for gene delivery, is one of the most effective non-viral gene carriers *in vitro* and *in vivo* because of its unique combination of high charge density and enhanced “proton sponge effect” in endolysosome. High molecular weight PEI shows high transfection activity, but the high degree of toxicity of PEI to cells was caused by its membrane disruptive properties. Many approaches, such as acetylation of PEI and incorporation of nontoxic derivatives, have been explored to reduce the genotoxicity of PEI, the transfection efficiency of the modified PEI decreased generally with the amino modification of PEI.¹

Herein, we developed a novel biodegradable gene targeting nano-carrier for rapid endothelialization of endothelial cells (ECs) *in vitro*. We synthesized biodegradable amphiphilic copolymers having targeting peptides to form the nano-carriers with ZNF580 and VEGF genes by self-assembly.

EXPERIMENTAL METHODS

Three triblock amphiphilic copolymers, methoxy-poly(ethylene glycol)-block-poly(3(S)-methyl-2,5-morpholinedione-co-glycolide)-graft-polyethyleneimine (mPEG-b-P(MMD-co-GA)-g-PEI) with different 3(S)-methyl-2,5-morpholinedione and glycolide content were synthesized. Nanoparticles (NPs) were obtained via self-assembly of these copolymers.

The triblock copolymers were characterized by FT-IR, DSC, GPC and ¹H NMR. The morphology and properties of nanoparticles were evaluated by TEM, gel electrophoresis, zeta potential and particle size analysis. Cytotoxicity, cellular uptake and transfect efficiency were evaluated with EA. hy926 cells *in vitro*.

RESULTS AND DISCUSSION

mPEG was introduced as the initiator to form a hydrophilic corona due to its high hydrophilicity and flexibility of the backbone. As an effective cyclopeptide, 3(S)-methyl-2,5-morpholinedione (MMD) was copolymerized with glycolide (GA) to form the polydepsipeptide structure. The molecular weight of diblock copolymers and the content of mPEG, MMD

and GA in copolymers were estimated by ¹H NMR and/or GPC. The triblock mPEG-b-P(MMD-co-GA)-g-PEI copolymers were prepared by reaction with PEI through a reactive spacer, and also covalently linking with targeting peptides CAG or REDV.

Fig. 1 NPs/gene complexes were prepared by self-assembly of three triblock amphiphilic copolymers and DNA condensation.

Nanoparticles (NPs) were obtained via self-assembly of these copolymers. The hydrophobic core composed of P(MMD-co-GA) segments provide crosslinking points for numbers of PEG and short PEI chains to form a high hydrophilic and positive charged corona/shell of NPs. Using these NPs, VEGF gene, ZNF580 gene for rapid endothelialization were efficiently transported into EA.hy926 cells. Because of hydrophilic PEG chains and low molecular weight PEI in the triblock copolymers, the cytotoxicity of these NPs and their complexes with pEGFP-ZNF580 was decreased significantly. The transfection efficacy of NPs/pEGFP-ZNF580 complexes was as high as LipofectamineTM 2000 reagent to EA.hy926 cells *in vitro*. The proliferation and migration of EA.hy926 cells were improved greatly by the expression of pEGFP-ZNF580 after 60 hours.

CONCLUSION

The mPEG-b-P(MMD-co-GA)-g-PEI based NPs could be a suitable non-viral gene carrier for ZNF580 gene to enhance rapid endothelialization.

INTRODUCTION

Cardiovascular disease is the leading cause of death worldwide, accounting for 29% of all global deaths and is set to rise to 23 million deaths a year by 2030¹. Arterial bypassing is generally performed with autologously harvested vessels or synthetic grafts. However, for small diameter vasculature (<6 mm), synthetic and autologous grafts suffer from poor patency rates due to thrombosis, aneurysm formation and compliance mismatch. Thus, the focus of this project is the development of a tissue engineered blood vessel (TEBV) for small diameter vessels.

In this context, the aim of this study was to develop a scaffold with optimised intrinsic physiochemical characteristics which displayed the capacity to support smooth muscle cells in vitro while subsequently displaying suitable viscoelastic properties capable of sustained biomechanical conditioning in a custom designed pulsatile bioreactor. In addition, in order to emulate the architecture of native vessels we investigated novel fabrication methods to develop a multi-layered tubular architecture.

EXPERIMENTAL METHODS

Elastin is a key component of native vasculature where it is responsible for the elastic recoil of vessels and has been shown to have a role in smooth muscle cell (SMC) behaviour². Thus, in this study, an elastin and collagen type I tubular composite scaffold was developed with the aim of providing a more natural viscoelastic response and to control SMC activity. An advanced biofabrication technique was developed which enabled the construction of a bilayered tubular construct via a combination of dehydration, freeze-drying and crosslinking.

Mechanical properties were analysed by uniaxial tensile testing, creep testing, and cyclical strain recovery to determine the viscoelastic response. Microstructure was analysed via porosity, pore size analysis and scanning electron microscopy. Subsequently, we evaluated the biological response by assessing the effect of elastin addition on SMC phenotypic modulation towards a synthetic or contractile phenotype, which was assessed via proliferation and gene expression analysis. Additionally, histology was carried out to determine the distribution of collagen and elastin as well as a qualitative assessment of the ability of smooth muscle cells to adhere to, migrate and proliferate within the scaffolds following 28 days culture.

RESULTS AND DISCUSSION

Elastin caused a more natural viscoelastic response via increased creep resistance and improved recoil ($p < 0.05$). Additionally, elastin addition resulted in earlier gene expression of mid/late stage contractile smooth muscle cell proteins which are necessary for a

vasoactive vessel. This biomimetic biomaterial was subsequently fabricated into an innovative architecture which partially emulates native architecture through its bilayered tubular structure. The outer porous layer was found to have a pore size ($\sim 90\mu\text{m}$) and porosity ($\sim 98\%$) in the ideal range to support cells while the dense inner layer was designed to support a confluent endothelium and increase the grafts mechanical properties. Following 28 days culture the SMC seeded tubular scaffold was remodelled into a dense organised tissue with a homogenous cell distribution.

Figure 1 Macroscopic bilayered tubular collagen-elastin scaffolds (A), under SEM (B), following 28 day culture the construct was remodelled to a dense tissue (C) the organised matrix can be seen via H & E staining (D).

CONCLUSION

In this study, we have shown that elastin addition to collagen scaffolds can play a major role in the scaffolds biological and mechanical response. Collectively, this study has led to the development of a composite scaffold with optimised intrinsic physiochemical characteristics which displayed the capacity to support smooth muscle cells in vitro while subsequently displaying suitable viscoelastic properties. This multi-layered collagen-elastin scaffold represents an excellent scaffold choice for further culture in a biomimetic environment to produce a functional tissue engineered vascular graft. Consequently, ongoing research focuses on the application of dynamic biophysical stimulation within a custom-built vascular bioreactor to aid in the maturation of the engineered blood vessel.

INTRODUCTION

Polyurethanes (PU) are the commonly used for cardiac valves, vascular prostheses, and heart assisting devices due to their acceptable blood compatibility and mechanical properties [1,2]. Nonetheless, polyurethanes are susceptible to hydrolytic degradation, encrustation and thrombosis [3]. Therefore, materials with improved biocompatibility and antimicrobial properties are still needed. Here, the basis for such materials are segmented copolymers with microphase separated structure (similar to segmented polyurethanes), but composed of hard segments as in poly(ethylene terephthalate) (PET). In this multiblock copolymer, the soft segments were composed of hydrophobic ethylene esters of dimerized fatty acid (DLA).

The present work will focus on the static mechanical properties and microbiological properties of new segmented polyester TPE containing dimerized fatty acid (PED), proposed as alternative material to PU.

EXPERIMENTAL METHODS

Static mechanical testing was performed with Instron 3366 according ISO 527-1:1998 at 22 and 37°C. TPU was used as reference material. *E. coli* cells were cultured on the surface of PED and reference PU polymers, respectively. The samples were incubated for 24 h in a medium containing *E. coli* cells (ATCC25922 strain) at 37°C under stationary conditions. After incubation, sample surfaces were extensively washed with deionised water and labelled by immersion in 1 ml PBS and 100µl MTT. The bacterial cells colonization was evaluated based on spectrophotometric measurements of absorbance at $\lambda=570$ nm.

RESULTS AND DISCUSSION

PED material containing 50wt% hard segments showed static mechanical properties comparable to medical grade PU (Table 1). The influence of temperature on mechanical stability of both PED and TPU materials is observed, modulus drops with increasing temperature, however for the polyester, decrease of the values is significantly lower than for polyurethanes.

The material susceptibility to *E. coli* colonization was assessed. PED showed distinctly reduced number of adhered bacteria ($0.026 @ \lambda=570\text{nm}$) as compared to medical grade polyurethane $0.033 @ \lambda=570\text{nm}$). The

reduced material susceptibility to microbial colonization is explained by the presence of fatty acids in PED-50, which have antimicrobial activity [4].

Table 1 Comparison of mechanical properties

Material	E @ 0,25-1% strain (MPa)	E @ 50 % strain (MPa)	E @ 100% strain (MPa)
PU @ 22°C	140,7±19,4	18,8±0,6	11,2±0,24
PED-50 @ 22°C	75,5±24,1	18,8±0,4	10,1±0,2
PU @ 37°C	66,6±10,2	10,2±0,5	5,7±0,3
PED-50 @ 37°C	48,6±3,6	16,1±0,5	8,6±0,3

Incorporating dimerized fatty acids into PED structure increases the number of carbonyl groups (hydrophilic) and methyl pendant groups (hydrophobic), resulting in a polymer with amphiphilic properties. We speculate that reduced number of adhered bacteria to PED surface can be attributed to such amphiphilic structure. Further it is possible, that these properties may also have a direct antimicrobial effect.

CONCLUSION

New segmented polyester TPE containing dimerized fatty acid (PED-50) shows markedly improved mechanical characteristics, compared to medical grade PU. PED-50 also showed diminished microbial colonization. This material offers great promise of higher safety and better performance in heart assisting devices.

INTRODUCTION

Aorta tissue regeneration is quite important with consideration of the high prevalence of cardiovascular diseases. Cardio-vascular tissue engineering has produced a number of artificial vascular graft materials for the replacement of failed vessels¹. In addition to synthetic graft materials, decellularised tissue-engineered vascular grafts (TEVGs) have gained great attention due to their innate high immunological compatibility.

Most approaches to tissue decellularisation are based on chemical treatment methods where ionic, non-ionic detergents or enzymatic agents are applied. It was reported that the ionic detergent SDS (Sodium Dodecyl Sulfate) effectively removes cells and nuclear remnants whilst preserving ECM (Extra Cellular Matrix) structure². In this study, we have decellularised bovine aorta using a supercritical fluid extraction technique.

EXPERIMENTAL METHODS

Fresh bovine aorta samples obtained from a local farm (Kazan, Turkey) were dissected into 1 g annular pieces. These aorta samples were treated with supercritical carbon dioxide (sc-CO₂) in a supercritical fluid reactor (SFT, USA) at different pressures and for different time periods. In these experiments the temperature remained at 35 °C, the pressure was varied between 15 MPa and 20 MPa and treatment time was varied between 20 and 50 minutes. Ethanol was used as a co-solvent and, before treatment; the supercritical fluid reactor was filled with 20 ml ethanol (Sigma, Germany). Aorta samples were placed inside a porous metal carrier, which was then placed into the reactor. The degree of decellularisation was evaluated histologically by Haematoxylin-Eosin (H&E) staining and displayed microscopically (Olympus, Japan). In parallel with these treatments, chemical decellularisation was also performed using the ionic SDS detergent. Aorta samples were incubated in hypotonic 10 mM Tris Buffer (pH: 8.0) with 0.1% EDTA for 1 h. They were then exposed to continuous shaking in a solution of 0.1 % SDS with Tris buffer (10 mM Tris, pH 8.0) together with RNase A (20 µg/ml) and DNase (0.2 mg/ml) at 37°C for 48 h³. Subsequently, they were washed several times with PBS to remove excess chemical residues.

RESULTS AND DISCUSSION

Figure 1 shows that the aorta treated with sc-CO₂ (c) and 0.1% SDS (b) is quite different from native tissue (a). Both sc-CO₂ + ethanol and 0.1% SDS treatment completely removed cell nuclei from the ECM.

Additionally, the ECM structure of the sc-CO₂-treated aorta was preserved more than the SDS-treated aorta. The SDS-treated aorta showed a slightly loosened collagen waveform when compared to the sc-CO₂-decellularised aorta.

Figure 1 . Haematoxylin and Eosin staining of bovine aorta treated with supercritical carbon dioxide and SDS a) native aorta (40x). b) aorta treated with 0.1% SDS 48 h (40x). c) aorta treated with sc-CO₂ + ethanol (40x) (P=20 MPa, T=35°C, t=50 min).

As a result, the high transfer rate and high permeability of sc-CO₂ has established it as a successful decellularisation agent. Both characteristics allow the easy and complete penetration of the tissue at supercritical conditions (T:32 °C, P: 7.4 MPa).

CONCLUSION

Nearly all-chemical decellularisation protocols are based on excessive and time consuming procedures, which can take up to several weeks. Furthermore, detergents have a strong affinity to the ECM and even after several washing operations chemical residues cannot always be effectively removed. The decellularisation process disclosed in this abstract carries superiority to chemical decellularisation procedures as not only is the carbon dioxide removed completely from the tissue without leaving remnants after treatment but the method also takes a significantly shorter amount of time.

Hemocompatibility Assessment of Uncoated and Heparin Coated Styrenic Block Copolymers for Cardiovascular Applications

Jacob Brubert^{1*}, Joanna Stasiak¹, Geoff Moggridge¹ and Hans Peter Wendel²

¹Department of Chemical Engineering and Biotechnology, University of Cambridge, UK jbb41@cam.ac.uk

²Department of Thoracic, Cardiac, and Vascular Surgery, University Hospital of Tuebingen, Tuebingen, Germany

INTRODUCTION

Owing to excellent mechanic properties, and easy processibility, styrenic thermoplastic elastomers (STE) have gained increasing interest in recent years as potential biomaterials. Furthermore, certain triblock copolymer STE may exhibit a cylindrical morphology with anisotropic mechanical properties, akin to those resulting from collagen orientation in some tissues, heart valve leaflets for example¹.

EXPERIMENTAL METHODS

4 compression moulded cylinder-forming block copolymers were examined: polystyrene-*block*-polyisoprene-*b*-polystyrene (SIS), containing 30wt% styrene from Kraton polystyrene-*b*-polyisoprene-*b*-polybutadiene-*b*-polystyrene (SI/BS), containing 19wt% styrene, and polystyrene-*b*-polyethylene-*b*-polypropylene-*b*-polystyrene (SEPS), containing 22wt% styrene, all from Kraton, and polystyrene-*b*-polyisobutylene-*b*-polystyrene having 30wt% styrene, manufactured by Innovia LLC., denoted as SIBS. SEPS was subsequently heparin coated (Corline) (SEPS-HEP). ePTFE, polyester (PE) and glutaraldehyde fixed bovine pericardium (BP) were used as reference materials.

Freshly drawn human whole blood was circulated for 90 mins in an in vitro closed loop model (modified Chandler-Loop)². Blood compatibility tests were performed according to ISO 10993-4, including measures of thrombogenicity, activation of coagulation, blood cell counts, platelet activation, and neutrophil inflammatory response. Biomaterial samples were also analysed with scanning electron microscopy.

RESULTS AND DISCUSSION

Polyester resulted in the greatest activation of the coagulation pathway as indicated by TAT complex formation, and uncoated STEs lead to moderate activation. ePTFE and heparin coated materials lead to minimal activation of the coagulation pathway.

Levels of PMN-Elastase indicated that STE biomaterials resulted in significantly less leukocyte activation than polyester, and comparable to ePTFE.

The full blood count showed no significant differences between biomaterials and ePTFE. However, STE biomaterials resulted in significantly greater levels of β -thromboglobulin release than in blood contacted with ePTFE.

No significant thrombus generation was seen on the biomaterials under SEM, and protein adsorption levels (Fibrinogen and CD41) were similar to ePTFE.

CONCLUSION

Uncoated STE biomaterials are superior to polyester, and bovine pericardium, but inferior to ePTFE, in measures of hemocompatibility.

Heparin coating of STE biomaterials results in hemocompatibility comparable to ePTFE.

STE biomaterials continue to show potential for cardiovascular implant applications.

Capillary morphogenesis of primary endothelial mono- and co-cultures in starPEG-heparin hydrogels for controlled vascularization

Uwe Freudenberg, Karolina Chwalek, Mikhail V. Tsurkan, and Carsten Werner

Leibniz Institute of Polymer Research Dresden (IPF), Max Bergmann Center of Biomaterials Dresden (MBC) & Technische Universität Dresden, Center for Regenerative Therapies Dresden (CRTD), Dresden, Germany, freudenberg@ipfdd.de

INTRODUCTION

Angiogenesis, the outgrowth of blood vessels, is crucial in development, disease and regeneration. Studying angiogenesis *in vitro* remains challenging because the capillary morphogenesis of endothelial cells (ECs) is controlled by multiple exogenous signals. Therefore, a set of in situ-forming starPEG-heparin hydrogels was used to identify matrix parameters and cellular interactions that best support EC morphogenesis.

EXPERIMENTAL METHODS

Hydrogels were synthesized utilizing multifunctional starPEG-peptide-conjugates and maleimide pre-functionalized heparin.¹ Primary human vein endothelial cells (HUVECs) were cultured together with primary human aortic smooth muscle cells (SMCs), primary human dermal fibroblasts (HDFs) or human bone marrow mesenchymal stem cells (MSCs) applying cell-responsive starPEG-heparin hydrogels pre-functionalized with RGD-peptides, and pro-angiogenic factors (VEGF, FGF-2 and SDF-1)². The formation of tubular networks was analyzed utilizing time lapse microscopy, immunostaining combined with confocal laser scanning microscopy and transmission electron microscopy.

RESULTS AND DISCUSSION

First, the influence of mechanical matrix characteristics and the presentation of bioactive components to EC network assembly was investigated. We found, that a particular type of soft, matrix metalloproteinase-degradable hydrogel containing covalently bound integrin ligands (RGD) and reversibly conjugated pro-angiogenic growth factors (VEGF, FGF-2 (F) and SDF-1 (S)) could boost the development of highly branched, interconnected, and lumenized endothelial capillary networks.

Figure 1: Capillary network formation is improved by the synergistic effect of VEGF165, FGF-2 (F) and SDF1-a (S): Mean branch length and branch density/mm² were quantified showing superior effect of soft hydrogels (200 Pa) containing VEGF165, FGF-2 and SDF-1a. *p , 0.05, **p , 0.01, ***p , 0.001, ANOVA.

Using these effective matrix conditions, 3D heterocellular interactions of ECs with different mural cells were demonstrated that enabled EC network modulation and maintenance of stable vascular capillaries over periods of about one month *in vitro*. Co-culture with MSCs resulted in the longest average branch length that contributed to the higher overall network density, while no significant differences were observed for the other co-cultures.

Figure 2: Left: Image of fluorescently labeled endothelial cells (red, CMFDA) co-cultured with 10% MSC (green, CMTMR) at 28 days showing capillary network in gross scale. Middle: Immunostaining of endothelial cells (green, CD31) and MSCs (red, F-actin) during the long-term culture showing cell co-localization. Right: Confocal longitudinal and cross-section image of a 28 day-old endothelial cell capillary (red-f-actin, green-CD31, blue-nucleus) showing its multicellular composition and internal lumen.

CONCLUSION

In summary, starPEG-heparin hydrogels enabled the long-term *in vitro* investigation of heterotypic cell-cell interactions during EC capillary formation, highlighting the important regulatory role of supporting mural cells in the angiogenic EC microenvironment. The combination of various different mural cells with the multifactor delivery in the hydrogel-based co-cultures of ECs facilitated the most versatile modulation of capillary EC networks, and could offer unprecedented options for generating tissue and disease-specific angiogenesis models.

The Zeta Potential as Indicator for Solid Surface Charge

Christine Körner^{1*} and Thomas Luxbacher¹

¹Anton Paar GmbH, Austria
christine.onitsch@anton-paar.com

INTRODUCTION

Surface characteristics play a vital role in the biocompatibility of any material. Studying surface properties is thus of paramount importance, as the outermost surface layer of a material has a tremendous effect on the success or failure of a biomaterial.

The present work deals with the role of zeta potential analysis as a surface sensitive technique for the characterization of biomaterial surfaces. The zeta potential is an interfacial parameter which describes the charge a surface assumes when it gets in contact with a liquid. Zeta potential analysis furthermore enables time-resolved adsorption studies of biological compounds on solid surfaces, thus contributing to the understanding of e.g. protein-biomaterial interaction.

Zeta potential analysis is applicable to all classes of materials used for biomaterial applications, i.e. metals, polymers and ceramics.

EXPERIMENTAL METHODS

Zeta potential analysis of various materials was performed with SurPASS Electrokinetic Analyzer.

The SurPASS method is based on the streaming potential or streaming current technique, respectively. If a surface is brought in contact with the electrolyte solution, charges are formed at the solid-liquid interface. Upon streaming the electrolyte solution across the solid surface, the charge distribution on the surface is shifted, giving rise to a – so called – streaming potential at the interface. The streaming potential is then used to calculate the zeta potential.¹

The zeta potential strongly depends on the pH value. The pH value where the zeta potential is 0 mV and a charge reversal takes place is called isoelectric point and describes the chemistry of a surface.

Being sensitive to the outermost surface layer of a material, the zeta potential is also used to assess adsorption processes².

RESULTS AND DISCUSSION

Figure 1 shows zeta potential vs. pH dependences of the inner surface of a poly(ethersulfone) (PES) hollow fiber membrane used for hemodialysis before applying surface treatment (1), after grafting with amino groups (2) and after final surface modification with heparin (3). The three curves allow for clear differentiation of the individual treatment steps: The isoelectric point of the

inert PES membrane is shown at pH 4, whereas it is shifted to alkaline pH (pH 8.2) after grafting with the amino groups, which behave basic. After subsequent treatment with heparin to increase the biocompatibility of the membrane, the surface charge was found to be negative due to the presence of sulfonic acid groups of heparin which dissociate when exposed to the electrolyte solution.

Figure 1: pH dependence of zeta potential for poly(ethersulfone) hollow fiber membrane with different surface treatment.

The results indicate the applicability of zeta potential analysis to study biocompatible surface coatings at real samples.

CONCLUSION

Zeta potential analysis is a valuable tool for the study of surface characteristics of biomaterials. A major benefit of the SurPASS method is its application to biomaterial samples of different shapes and geometries.

While the pH dependence of zeta potential provides information on the surface chemistry, the real-time study of adsorption kinetics furthermore enables the optimization of solid surface properties.

Zeta Potential: a Useful Tool to Interpret the Hydrothermally Treated Titanium Behaviour as Biomaterial

Martina Lorenzetti^{1,2,*}, Thomas Luxbacher³, Spomenka Kobe^{1,2} and Saša Novak^{1,2}

^{1,*}Department of Nanostructured Materials, Jožef Stefan Institute, Ljubljana, Slovenia, martina.lorenzetti@ijs.si

²Jožef Stefan International Postgraduate School, Ljubljana, Slovenia

³Anton Paar GmbH, Graz, Austria

INTRODUCTION

Titanium is considered one of the most suitable materials for hard tissue replacement, due to its mechanical properties and bioinertness. It owes its properties mainly to the thin naturally-formed, amorphous TiO₂ film present on its surface. However, this unstable, thin film can be replaced by a firmly attached, hydrothermally-grown polycrystalline TiO₂-anatase coating, in order to enhance the surface properties of the bare titanium^{1,2}.

The study of the surface properties of a biomaterial is compulsory for interpreting their “bio” performances *in vivo*. The surface charge is one of the most relevant characteristics for understanding the events happening at the interface, when the biomaterial comes in contact with the human body. In particular, it is known that proteins from the blood stream are the first macromolecules which adsorb on the biomaterial surface³.

Thus, the purpose of this work was to study the surface properties of polycrystalline TiO₂-coatings, in connection with their nanostructure, by analysing the zeta potential and the protein adsorption on such surfaces.

EXPERIMENTAL METHODS

A series of polycrystalline, nanostructured TiO₂-coatings were prepared by hydrothermal treatment (HT) of titanium substrates, following the procedure previously described^{1,2}. In short, machined titanium discs were hydrothermally treated in aqueous suspensions of Ti(iOPr)₄ at 200 °C in different pH conditions and different times.

The surface nanostructure and crystal morphology were observed by scanning electron microscopy (SEM), while the surface wettability was examined by sessile drop contact angle (CA) measurements.

The zeta potential of bare (Ti NT) and HT titanium substrates was determined by the streaming current technique, using a SurPASS electrokinetic analyzer (Anton Paar GmbH, Graz, Austria). Potassium chloride (KCl) and phosphate buffer saline (PBS), with an ionic strength of 0.001 mol/l in both cases, were used as analytical solutions. Bovine serum albumin (BSA), dissolved in PBS, was used as model protein for the adsorption analysis.

RESULTS AND DISCUSSION

The SEM pictures revealed that the HT coatings varied in their nano-texture, since they were constituted of crystals of different morphologies and dimensions, depending on the synthesis route. Accordingly, diverse properties in terms of wettability and charge were expected.

The HT discs displayed a more hydrophilic character compared to the bare titanium, suggesting a higher presence of hydroxyl groups and higher surface energy. The streaming potential measurements revealed that all the surfaces were negatively charged at physiological pH (7.4). However, the surface charge of the HT samples was significantly different compared to the Ti NT. The zeta potential curves also showed a different behaviour among the substrates, which was even more highlighted when the analytical solutions were switched.

The different zeta potential affected the BSA adsorption, but not its adsorption kinetics.

All these differences were ascribed to the surface dissimilarities among the HT-Ti and Ti NT from the chemical point of view, especially due to the presence of hydroxyl groups and to the adsorption of ions from the solutions (e.g. phosphate ions contained in the PBS buffer).

CONCLUSION

Surface zeta potential analysis represents a valuable tool to estimate the behaviour of titanium and modified-titanium surfaces (namely, TiO₂-coated) under chosen conditions (e.g. physiological conditions).

This helped to make assumptions and a better interpretation for further *in vitro* experiments carried out on such substrates.

The Role of Porosity on the Z-Potential of Calcium Phosphate Cements

Montserrat Espanol^{1,2,*}, Gemma Mestres³, Thomas Luxbacher⁴, and Maria-Pau Ginebra^{1,2}

¹Department of Materials Science and Metallurgical Engineering, Technical University of Catalonia, Spain

²Biomedical Research Networking Center in Bioengineering, Biomaterials, and Nanomedicine, Spain

³Department of Engineering Sciences, Uppsala University, Sweden

Montserrat.espanol @upc.edu

INTRODUCTION

Calcium Phosphate Cements (CPC) have long been recognized as excellent candidates in bone regeneration applications. Their great acceptance arises from their close similarity, both in composition and structure, to the mineral phase of bone. Another property that makes CPCs very unique is that they are injectable and by means of a simple dissolution-precipitation reaction are capable of hardening in the body. For cement formulations consisting of alpha-tricalcium phosphate (α -TCP), the set product results in an entangled network of nano- and sub-micron crystals of calcium deficient hydroxyapatite (CDHA). In spite of the many advantages that can be sought from such materials they are extremely challenging when it comes to interpretation of *in vitro* and *in vivo* data. One of the causes is the porous network created by the entangled crystals. Pores can concentrate and retain proteins as a function of their size altering the biological behaviour of the material¹. Along the same line it is reasonable to think that the presence of pores can alter the ionic species and ionic concentrations modifying in turn the surface potential of the material². The objective of the present work is thus to determine the zeta potential (ZP) of a series of CPC with various textures and porosities.

EXPERIMENTAL METHODS

CPCs were prepared by mixing a solid phase (98% α -TCP and 2% of precipitated hydroxyapatite) with a 2.5wt% of Na_2HPO_4 as liquid phase at two different liquid to powder ratios (L/P): 0.35 and 0.65ml/g. In addition, two α -TCP powders with different particle size were used: coarse (C) with a median size of 5.2 μm and fine (F) of 2.8 μm . Upon mixture of both phases the paste formed was mould in rectangles of 20mm (L) x 10mm (W) x 1mm (T) which were then allowed to set in water at 37°C for 4 days. The set cements were characterised by scanning electron microscopy (Jeol JSM-7001F), N_2 adsorption (ASAP2020) and mercury intrusion porosimetry (Autopore IV 9500 Micromeritics). A SurPASS electrokinetic analyzer (Anton Paar GmbH) was used to perform streaming current and cell conductance measurements by means of an adjustable-gap cell. The rectangular samples were fixed on sample holders with superglue and allowed to equilibrate overnight in 1mM KCl solution (500ml) before measurement. Measurements were performed at various cell gaps (80-120 μm) to separately determine the ZP of the cement and the conductance within pores.

RESULTS AND DISCUSSION

It is now well established that the porous structure of a material affects the surface ZP value owing to their

electrical conductance. Recent investigations have further proved that through streaming current and conductance analysis at different cell gaps it is possible to determine the ZP of both the external surface and the internal pore surfaces of a material². This has been implemented in the determination of the ZP of two CPC: C and F (Fig.1). Both cements share in common their identical chemistry and degree of porosity (55%), and they differ in their structure: F is built by the entanglement of needle-like crystals and C is composed of a mesh of larger plate-like crystals. The good fit obtained for the streaming current against gap cell allow to accurately determine the external ZP. Both textures resulted in very close external ZP values and in a negligible effective internal ZP. In spite of the fact that the conductance inside the pores in the F sample is very high as compared to the C sample, this does not necessarily imply it should contribute to the streaming current. The results in fact seem to support that the pores are too narrow to make any substantial contribution to the streaming current but further work is ongoing to fully confirm the results.

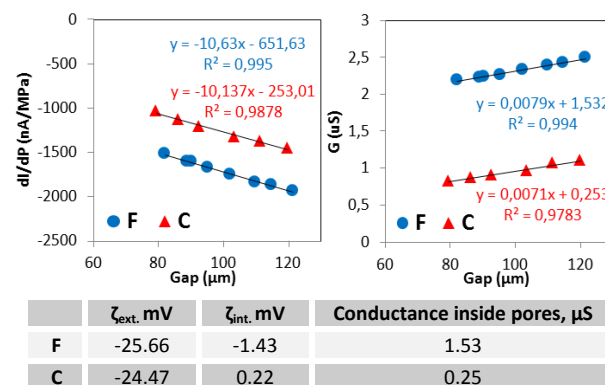

Figure 1. Streaming current and conductance analysis.

CONCLUSION

Although C and F cements had the same porosity, the different pore textures created by the entanglement of needles (F) or plates (C) were believed to be responsible for the differences in pore conductance. These differences did not affect the external ZP, which was found close to -25mV in both materials.

The effect of surface oxygen functional groups on parylene C biocompatibility - comparison of MG-63 cells adhesion and bacteria strains attachment

M. Gołda-Cępa¹, M. Brzychczy-Włoch², K. Envall³, A. Kotarba¹

¹Faculty of Chemistry, Jagiellonian University, Krakow, Poland, golda@chemia.uj.edu.pl

²Department of Microbiology, Medical College, Jagiellonian University, Krakow, Poland

³Department of Chemical Engineering and Technology, KTH Royal Institute of Technology, Stockholm, Sweden.

mild oxygen plasma treatment of parylene C implant coating was evaluated as a tool for tuning of its surface morphology and biocompatibility (MG-63 cell line and *S. aureus*, *S. epidermidis*, *P. aeruginosa* from ATCC and clinical isolates). It was found that the surface of modified parylene C promotes MG-63 cells growth and at the same time does not influence bacteria strains adhesion. The results are discussed in terms of changes in chemical (oxygen insertion into the polymer matrix) and physical (surface nanotopography) properties.

INTRODUCTION

Internal biomaterial devices *in vivo* meet several challenges, among which the risk of material-associated infection and lack of tissue integration¹ belongs to the most important. Upon implantation, 'race for surface' takes place when process of tissue cell integration compete with bacterial adhesion to the medical device's surface. Microbial colonisation of the surface can cause serious infection which can lead to complications². For these reasons, biomaterial surface properties are currently vividly investigated and nanostructured materials are becoming promising in tailoring adequately the surface. A parylene C versatile polymer coating which limits the corrosion and heavy metal ions release from the metallic biomaterials can be adjusted to meet the current requirements. One of the methods of polymer surface modification that can be successfully applied is oxygen plasma. Treatment with oxygen can affect not only the composition of the surface functional groups, but also nanotopography of the polymer. As a result, an opposite behaviour of osteoblast cells and bacteria strains can be observed on the same surface - promotion of osteoblast function and reducing bacteria colonisation.

EXPERIMENTAL METHODS

Parylene C (8 µm of thickness) films were prepared by CVD technique (provided by ParaTech Coating Scandinavia AB). In order to modify the parylene C surface, the oxygen plasma treatment was carried out using a Diener electronic Femto plasma system. The etching parameters were selected in order to obtain a nanotopography within the range of 30–200 nm. For evaluation of cell adhesion, the MG-63 human osteosarcoma cell line was used. In the experiments, both kinds of samples, unmodified and treated with oxygen plasma, were used. Cells were grown for 24 h in 24-well tissue culture plates. For fluorescence confocal microscopy observations cells F-actin and nucleus were stained. The bacteria strains used in the study were

S. aureus, *S. epidermidis* and *P. aeruginosa*. The method applied to assess bacterial adhesion to the parylene C films was the static adhesion assay³. The experiments were performed in 24-well tissue culture plates and incubated for 4 h in 1 mL of a bacteria strain suspension (5×10^8 CFU/mL).

RESULTS AND DISCUSSION

The fresh and modified samples were thoroughly characterised by AFM, SEM, XPS, contact angle measurements (Fig. 1). The modified parylene C surface does promote the MG-63 cells attachment and does not promote higher bacteria stains attachment and biofilm formation. On the unmodified parylene C, only few cells/mm² could be observed (ca. 20 cells/mm²±3), while for the modified sample an increase in adhesion was observed (ca. 120 cells/mm²±5). The attachment of the bacteria strain *S. aureus* was 1.7×10^5 for the unmodified sample and 3.4×10^5 for the oxygen-plasma treated. No significant differences were observed for any of the investigated strains.

Fig. 1 The effect of oxygen plasma on parylene C biofunctionality (*S. aureus*, MG-63, contact angle and SEM topography background).

CONCLUSION

The results show that generated surface nano-irregularities together with oxygen-containing groups can stimulate the MG-63 cells growth on a parylene C surface. At the same time, the modification does not enhance bacteria growth, as was proven in parallel tests with 6 bacteria strains.

INTRODUCTION

Wound healing represents a public health problem with an increase in susceptible populations like geriatric or diabetic patients¹. The major complication is infection, associated to an increase of morbidity (amputation) or mortality (septicemia). In particular, the infection of the diabetic wounds delays the healing process and progresses to bone destruction². We recently develop a wound dressing functionalized by layer-by-layer system based on chitosan (positive polyelectrolyte, PE+) and cyclodextrin polymer (negative polyelectrolyte, PE-) for synergic bi-therapy with silver or iodide associated to chlorhexidine.

EXPERIMENTAL METHODS

In a first step, the non woven polyester (PET) is functionalized by chitosan (CHT) crosslinked by citric acid (CTR) to obtain a first charged layer (positive or negative in function of the CTR concentrations) or by genipin to obtain a first positively charged layer only. The textile is characterized by FTIR, SEM and the ionic charge density is evaluated by titration. Then the positively and negatively charged PET-CHT is impregnated in iodine or silver solutions to obtain the first bioactive coating. The drug loading is quantified by elementary analysis and titration. In a second step, the multilayer system is build up on the loaded PET-CHT according to the method develop in our lab³ using alternatively cyclodextrin polymer (PCD, PE-) and CHT (PE⁺). In a last step, the multilayer system is impregnated in a chlorhexidine (CHX) solution. The CHX loading and CHX release is measured by HPLC method in function of the number of bilayers. Finally, the kinetic of release of the final wound dressing (PET-CHT-Ag/CHX and PET-CHT-I/CHX) is studied in physiological medium (PBS, pH7.4, 37°C, 80 rpm). The antibacterial activity is evaluated on different bacterial strains (*S. aureus* CIP224; *E. coli* K12; MRSA 07001 and *P. aeruginosa* ATCC 27583) by kill-time method. At each step of the functionalization process, the cytocompatibility is evaluated with epithelial cells (ATCC-CCL5, L132) according to ISO 10993-5 standard.

RESULTS AND DISCUSSION

The evaluation of the charge density on the functionalized PET with CHT shows the ability of the system to be adapted with the CTR concentrations either with an anionic exchange functions ([CTR] >1%) either with a cationic exchange functions ([CTR] <1%). After impregnation of anionic and cationic PET-CHT in silver and iodine solution, the titration shows a silver loading of 3% and iodine loading of 1600 ppm. *In vitro*,

microbiology evaluation reports the efficiency of the loaded PET-CHT. Indeed, the silver loaded PET-CHT reduces significantly two bacterial population after 24 hours (*S. aureus* : 4 log; *E. coli* : 5 log reduction).

The multilayer system, applies on the loaded PET-CHT, has three functions thanks to the cyclodextrin polymer as previously described⁴ i) barrier effect to reduce the release of the cytotoxic silver into the wound ii) gel formation to drain exudates iii) complex-inclusion formation to adsorb other drug. Systems with 5.5, 7.5 and 10.5 bilayers are performed on the PET-CHT-Ag. As show in figure 1a, the presence of silver has no influence on the build-up of the multilayer. Additionally, the figure 1b shows the CHX loading and CHX release depends on the number of bilayers.

Fig 1. a. Evolution of weight gain of textiles during the construction of the system. b. Kinetic of release of CHX in function of the number of bilayer (PBS, 80rpm, 37°C) (b).

The evaluation of cell vitality by the method of the Alamar blue shows an excellent cytocompatibility of the functionalization of the dressings at each stage of the process (vitality rate >70%). Finally, microbiological evaluation confirms the CHX release studies with a prolonged antibacterial effect (>30 days) of the Ag/CHX loaded on wound dressing against *S. aureus* and *E. coli*.

CONCLUSION

We demonstrate the safety and the prolonged antibacterial effect of a multilayer wound dressing loaded with silver or iodide associated with CHX. The three main characteristics of multilayer system (drug sorption, gel formation, ionic exchange capacity) allow us to obtain a new generation of wound dressing for combined biotherapy.

INTRODUCTION

Infection of implanted medical devices was associated with an estimated cost of \$3.3 billion in the USA in 2004, occurring at a rate of 3–5% across a range of implant types [1]. Bacterial biofilms on infected implants often evade antibiotic treatment, necessitating replacement surgery [2]. An anti-infective surface coating for surgical implants is required. The ideal surface also supports integration with host tissue, promoting long-term success by allowing a robust immune response at the tissue-implant interface [3]. Our strategy in developing such a surface is based on a biocompatible cationic antimicrobial peptide (CAP).

EXPERIMENTAL METHODS

Surface Preparation

Fluorinated ethylene propylene (FEP) was coated with a plasma polymer of allylamine (ppAA). The CAP containing a single cysteine residue was covalently attached to ppAA *via* the amine-to-sulphydryl crosslinker, succinimidyl-4-[N-maleimidomethyl]-cyclohexane-1-carboxylate (SMCC).

Bacterial Adhesion to Surfaces

Staphylococcus aureus, *Staphylococcus epidermidis* or *Escherichia coli* clinical isolates were grown in broth medium, and diluted to 10^6 CFU/ml. Sample surfaces were incubated with bacteria at 37°C for 48 h. Surfaces were then rinsed, and adherent bacteria were stained to determine viability and imaged by fluorescence microscopy. The percentage area covered by bacteria was measured with ImageJ software.

Cell Adhesion to Surfaces

Human primary epidermal keratinocytes or dermal fibroblasts, maintained in serum-free conditions, were seeded at 5×10^3 cells/cm² on sample surfaces. After 48 h surfaces were rinsed, and adherent cells were stained, imaged by fluorescence microscopy, and counted. Counts per experiment were normalised such that cell numbers on ppAA are reported as 100%.

RESULTS AND DISCUSSION

Antibacterial Activity of Surfaces

Coverage by viable bacteria on the CAP surface, compared to FEP and ppAA surfaces, was significantly ($p < .05$) reduced for the three strains tested (Fig. 1).

Cell Adhesion to Surfaces

Numbers of keratinocytes and fibroblasts on CAP were approximately 80% of those on ppAA (Fig. 2). For each cell type, cell counts were significantly ($p < .05$) different on all surfaces except for keratinocytes on FEP vs CAP.

Figure 1. Percent viable bacterial surface coverage on CAP compared to FEP and ppAA at 48 h ($n=3$). $*p < .05$

Figure 2. Human primary cell numbers on CAP compared to FEP and ppAA at 48 h ($n = 3$). $*p < .05$

Discussion

Relative to ppAA, our CAP surface reduces bacterial adhesion by 72% and 78%, respectively, for the *S. aureus* and *S. epidermidis* strains tested. These two Gram-positive species are responsible for two-thirds of all orthopaedic device infections [4]. Gram-negative *E. coli* is also susceptible to CAP, showing a 66% reduction. Our coating also allows mammalian cell adhesion and proliferation to about 80% of the level observed on the nonspecific, cell-compatible ppAA surface. Future experiments will examine the mechanism of adhesion to CAP, and test the biocompatibility and effectiveness of this surface *in vivo* in a rodent model.

CONCLUSION

Our *in vitro* results suggest our CAP is a good candidate for a surface coating for surgically implanted medical devices. Further investigation is warranted.

INTRODUCTION

Current medical facilities use antibiotics to prevent immune compromised patients from various types of infections. In this decade, we have faced a threat of emerging drug-resistant bacteria. Thus, there is a pressing need for development of new types of drugs with a broad spectrum of antimicrobial activity and capability not to develop drug-resistance.

Amphiphilic polycations mimicking host defence peptides (HDPs) physically break down negatively charged bacterial cell membrane by static interaction, contributing to no generation of drug-resistance¹. Nederberg et al. have reported that biodegradable polycarbonates with quaternary ammonium (PC3QA) are effective against drug-resistant gram-positive bacteria methicillin-resistant *Staphylococcus aureus* (MRSA)². However, PC3QA needed more hydrophobicity to affect more pathogenic gram-negative bacteria, which also resulted in lysis of healthy red blood cells (RBCs)³. One challenge in synthetic antimicrobials is combining high antimicrobial and low hemolytic activities⁴.

Figure 1. Synthesis of cationic polycarbonates

In this study, we synthesized similar aliphatic polycarbonates with primary ammonium (PC2PA) that can be partially deprotonated at neutral pH to form hydrophobic liberated amine. Some polymers with primary ammonium represent not only strong antimicrobial activity against gram-negative bacteria but also high hemolytic activity¹. Then we incorporate a blood compatible polycarbonate recently developed (PCME)⁶ into PC2PA to mitigate the potential hemolytic activity.

EXPERIMENTAL METHODS

Polymer Synthesis

Preparation and ring-opening polymerization (ROP) of MTC-BAE and MTC-ME (Fig. 1) have been already described elsewhere^{2,5}. The resultant polymers were then treated with trifluoroacetic acid (TFA) for deprotection of *tert*-butoxycarbonyl group (Boc) to generate primary ammonium salt.

Antimicrobial and hemolytic assays

Aqueous polymer solutions with different concentrations were incubated with human RBCs for 1 h and *E. coli* for 24 h at 37°C, respectively.

RESULTS AND DISCUSSION

Two polycarbonates were prepared in this study. PC2PA has all cationic residue and M_n 7,600. PC(2PA-ME) comprises 50% of cationic units and 50% of MTC-ME and has M_n 5,200 (PDI 1.38).

Figure 2. MIC against *E. coli* and HC₅₀ against human RBCs of each polymer (a). SEM images of *E. coli* before (b) and after (c) treatment with PC2PA

Both new cationic polycarbonates efficiently inhibited growth of *E. coli* with concentration (MIC) of 16 µg/mL. PC2PA induced 50% hemolysis at a concentration of 2000 µg/mL while PC(2PA-ME) remained hemolysis below 20% at a concentration over 3000 µg/mL. This implies that MTC-ME unit is beneficial to lowering hemolytic activity. In contrast, a typical cationic polymer PEI showed low antimicrobial and high hemolytic activities. (Fig. 2a). SEM observation revealed that PC2PA also disrupts bacterial cell membrane (Fig. 2b,c). Therefore, the PC2PA-based antimicrobials are expected to be effective against drug-resistant strains.

CONCLUSION

We successfully developed a blood compatible and antimicrobial polycarbonate potentially effective against drug-resistant bacteria.

INTRODUCTION

Development of antibacterial surfaces is a necessity to reduce the number of implant-associated infections¹. A promising strategy is to incorporate silver (Ag) in biocompatible and bioactive structures such as hydroxyapatite (HA) or TiO₂ coatings, combining osseointegration with broad antibacterial properties. The appropriate composition, structure and subsequent Ag⁺ release from such coatings is still, however, much under development². This study presents a combinatorial approach to synthesizing and evaluating antibacterial and other properties of a binary Ag-Ti oxide gradient, elucidating composition-structure-property relationships.

EXPERIMENTAL METHODS

A single sample was evaluated in this study, created using a combinatorial physical vapour deposition (PVD) system. Opposing targets of Ag and Ti were used concurrently in a reactive (O₂) environment to deposit a binary compositional gradient coating across a 3-inch Si wafer. The gradient was then characterized and tested against *S. aureus* in a 2h adhesion test, and Ag⁺ release profiles were retrieved from opposing ends of the sample.

RESULTS AND DISCUSSION

In Fig. 1, the structural and compositional differences between the Ag-rich and Ti-rich ends are depicted. The Ag-contribution in the sample shifted from an integral part of a homogeneous, rough, nanofeatured structure, to coalesce as scattered nanoparticles on the Ti-rich end.

Fig. 1. SEM images of (a) Ag-rich and (b) Ti-rich ends of the coating. Composition in wt%.

Results of the bacterial assay are shown in Fig. 2, where a >99% reduction in viable *S. aureus* count was noted after contact with the Ag-rich end, compared to a negative control. The centre and Ti-rich end of the sample presented 60% and 25% reductions in CFUs, respectively.

Fig. 2. CFU counts after 2h contact with three distinct parts of the sample, compared to a negative control.

The difference in Ag⁺ release from the two extremes of the sample is shown in Fig. 3, which explains the observed variety in antibacterial properties. This change in release properties is in turn explained by the structural variety of the Ag contribution along the gradient. Higher surface energy and surface area, along with smaller crystallite size and a larger degree of oxidized Ag served to increase the dissolution rate on the Ag-rich end.

Fig. 3. Cumulative Ag⁺ release profiles (in PBS) from Ag-rich and Ti-rich ends of the combinatorial sample.

CONCLUSION

By applying a combinatorial approach, a continuous compositional and structural gradient between Ag and Ti was synthesized. The findings suggest that aspects of structure, rather than composition, dictates the release of Ag⁺, which could be utilized to better tailor implant coatings with antibacterial properties.

INTRODUCTION

There is mounting evidence that suggests many wounds are now becoming infected due to the possible recalcitrant nature of complex dynamic biofilms. Consequently we investigated whether biofilms, microorganisms, which attached onto a surface, generally within microcolonies, and encase themselves within a three-dimensional matrix of extracellular material, are able to proliferate in and on wound dressings. If biofilms are able to grow within and on a wound dressing they would, unless locked into the dressing, become a vehicle for seeding bacteria and endotoxins together with their extracellular material i.e enzymes and exotoxins into the wound bed. The dressing would behave like a bioreactor and continually disseminate biofilm phenotypic bacteria into the wound bed increasing the wounds microbial bioburden and heightening its propensity to infection and disease.

EXPERIMENTAL METHODS

Biofilm Development on gauze: A single colony from a purity plate (containing either *Staphylococcus aureus*, *Pseudomonas aeruginosa* or *Candida albicans*) was inoculated into 10 ml of sterile Tryptone Soya Broth (TSB) so that approximately 1×10^7 cfu/ml was achieved. To a sterile container, 9mls of Tryptone Soya Broth/Foetal Bovine Serum (TSB/FBS 50:50) was added. Each container was inoculated with 1ml of the previously prepared 1×10^7 cfu/ml suspension.

Dressings (foam, gauze, alginate, carboxymethylcellulose - $2 \times 2\text{cm}^2$ in size) were cut and aseptically transferred into each container and incubated for 24 hrs at 35°C (± 3) in a shaking incubator set at 100rpm.

Biofilm Confirmation: After 24 and 72 hrs incubation each dressing was removed and washed twice in 10 mls of 0.85% saline to remove planktonic bacteria. Each dressing was stained with 50 μl LIVE/DEAD BacLight (Life technologies) and analysed under scanning confocal laser microscopy to determine evidence of biofilms.

Total Viable Counts (TVC): After 24 hrs incubation each dressing was removed and washed in 10 mls of 0.85% saline twice. Each dressing was then placed into 10mls 0.85% Saline in a sterile container and left to

stand for up to 24hours. After 2, 4, 6 and 24 hrs samples of the resulting suspension were removed and diluted in maximum recovery diluent (MRD). Plate counts were performed on tryptone soya agar (TSA) (*S. aureus* and *P. aeruginosa*) or sabouraud dextrose agar (SDA) (*C. albicans*). Plates were incubated at 35°C (± 3) (*S. aureus* and *P. aeruginosa*) and $20-25^\circ\text{C}$ (*C. albicans*) for at least 24hrs. This was repeated in triplicate.

Plate Transfer Test: After 24 hrs incubation each dressing was removed and washed in 10 mls of 0.85% saline twice. Each dressing was then placed on to the surface of a TSA (*S. aureus* and *P. aeruginosa*) or SDA (*C. albicans*) plate and left in place for 2 mins. Each dressing was transferred to a fresh TSA/SDA plate and left for a further 2 mins. This was repeated 3 more times. Plates were incubated at 35°C ($\pm 3^\circ\text{C}$) (*S. aureus* and *P. aeruginosa*) and $20-25^\circ\text{C}$ (*C. albicans*) for at least 24hrs. This was repeated in triplicate.

RESULT

After 24 hours biofilms were evident on all the dressings. The biofilms contained the characteristic microcolony formation and also showed evidence of extracellular polymeric substance. The TVC showed that the level of microorganisms released from many of the dressings remained at a steady, but high level throughout the test period. This was confirmed by the growth present on the transfer plates.

CONCLUSION

In conclusion microorganisms from acute and chronic wounds will migrate and adhere to wound dressings. However, unlike dressings, which are known to lock in microorganisms and their intracellular components, many wound dressings are not able to do this. Consequently gauze, as an example, may act by disseminating sloughed biofilm, released from the biofilm within the gauze, back into the wound bed, together with their extracellular components, e.g. toxins and enzymes, and ultimately delay wound healing or initiate infection within that wound.

Formation of Multicellular Spheroids on Arrayed Microwells with Microstructure

Masahito Ban*, Yuuya Kogi

Systems Engineering Major, Graduate School, Nippon Institute of Technology, Japan

*ban@nit.ac.jp

INTRODUCTION

The application of biomaterials with the micro and nanostructure to cell scaffolds remains to be unknown, and it has been a significant subject to clarify the effects of the structure on cellular behaviors. Our group reported that a linear concavo-convex structure with a size of several μm was formed on Polydimethylsiloxane (PDMS) substrate by depositing diamond-like carbon (DLC) thin film¹, and mouse myoblast cells (C2C12) had a tendency to adhere to and grow along the linear structure². In this study, arrayed microwells with concavo-convex microstructure were fabricated by combination method of ink-jet and DLC deposition, and in which C2C12 cells were cultured to evaluate the cellular shape and configuration.

EXPERIMENTAL METHODS

Toluene was discharged arrangedly in a honeycomb geometry on polycarbonate (PC) substrates using an ink-jet spotting system. PDMS was transferred using the discharged PC substrates as the mold, and the DLC thin films were deposited on the obtained PDMS substrates using an inductively-coupled plasma (ICP) CVD system. Once again, PDMS was transferred with the mold of the DLC-coated PDMS. The culture tests having C2C12 cells were performed with the cell concentration varied using the PDMS substrates transferred DLC-coated PDMS.

RESULTS AND DISCUSSION

The confocal laser microscope observation results in Fig. 1 revealed that the fabricated PDMS substrate had the arrayed microwells of circular concave shapes (about 100 μm in diameter) with several μm concavo-convex structure formed on the surface.

C2C12 cells cultured using the prepared PDMS substrate as a scaffold showed a tendency to aggregate on the bottoms of the microwells, and formed spheroid-like configuration. Fig. 2 indicates the observation results, (a) F-actins (green) by phalloidin and (b) cell nuclei (blue) by DAPI, by a fluorescence microscope. Numerous cell nuclei aggregated into the spherical

Fig. 1 Confocal laser microscope observation result of the fabricated PDMS substrate

Fig. 2 Fluorescence microscope observation results

Fig. 3 Variations of spheroid diameters vs. culture time

shape consisting of F-actins, implying that a multicellular spheroid of C2C12 was formed.

The average diameters of the spheroids as functions of the culture time and the cell concentration are shown in Fig. 3. In the case of the cell concentration of 1×10^6 , it was found that the spheroid grew up to about 100 μm corresponding to the diameter of the microwell in three days of culture.

CONCLUSION

The 100 μm -diameter spheroid of C2C12 cells was formed using the arrayed microwells with several μm concavo-convex microstructure.

brochhausen@pathologie.klinik.uni-mainz.de

INTRODUCTION

Macrophages play a crucial role in the function and regulation of inflammation and biocompatibility. Today it is well known that macrophages represent a dynamic cell type with several phenotypic groups (fig. 1). We use a standardized adhesion prevention animal model to analyse the efficacy, biocompatibility and inflammatory reaction of different barrier materials. To determine if the CD68-positivity, which is required by the ISO norm in biocompatibility testing, represent sufficiently all the macrophage types and there different functions we analysed CD-68 macrophages and compared it with the extent of fibrosis and inflammation after use of 5 different adhesion barriers and an untreated control group.

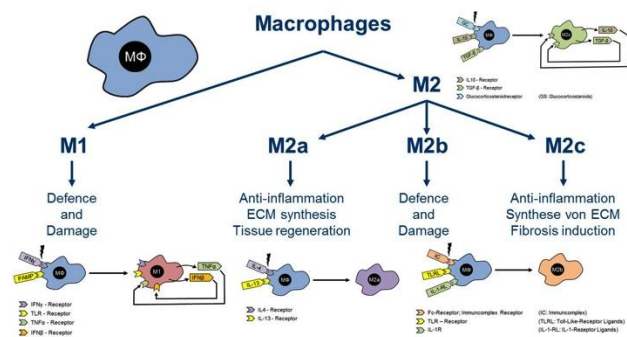

Fig. 1: Schematic depiction of the different macrophages and there characteristics

MATERIALS AND METHODS

Serosal wounding occurred by a standardised method in Wistar rats. The defects were left untreated (control) (n=14) or were treated with different clinically available barrier materials, namely Adept® (n=14) Intercoat® (n=33) Spraygel® (n=8), Seprafilm® (n= 29) and Suprathel® (n=14). After 14 days the animals were sacrificed and the treated tissue processed by standardised techniques for histological evaluation of fibrosis using Ladewig staining, haematoxylin & eosin and chloracetate esterase to estimate inflammation, as well as immunohistology using CD 68 staining to score macrophages. Histology was evaluated by two independent investigators.

RESULTS

No correlation was found between the number of CD68-positive macrophages and the amount of fibrosis or

inflammation. While some groups were associated with moderate infiltration of macrophages and no fibrosis (Intercoat[®] and Suprathel[®]), the Seprafilm[®] group revealed moderate inflammation with likewise moderate amounts of macrophages. On the other hand, a minimal number of macrophages was associated with minimal fibrosis in the control and Adept[®] group. Inflammation and macrophage infiltration were moderate in the Suprathel[®] group. In the Intercoat[®] and Seprafilm[®] treated animals moderate infiltration of macrophages was seen with minimal inflammation. Animals from the control and Adept[®] group revealed minimal inflammation and minimal macrophage infiltration. All in all, there was no correlation between the tissue response and the count of CD 68-positive macrophages (Table 1).

Table 1: Histochemical and immunohistological results

	Macrophages (CD68-positive)	Fibrosis	Inflammation
Control	minimal	minimal	minimal
Adept [®]	minimal	minimal	minimal
Spraygel [®]	mild	none	mild
Intercoat [®]	moderate	none	minimal
Seprafilm [®]	moderate	moderate	minimal
Surpathel [®]	moderate	none	moderate

DISCUSSION

The number of CD 68-positive macrophages does not predict tissue compatibility in adhesion prevention with respect to inflammation and fibrosis. Three different populations of macrophages have been described according to their activities in host defence, wound healing and regulation of immune response², and one subtype seems to participate in fibrosis during wound repair.^{3,4}

CONCLUSION

For biocompatibility studies the immunohistological subclassification of macrophages is required to clarify the role of macrophages during cellular reaction of biomaterials. This should be reflected regarding biocompatibility testing according to the ISO-norm.

Swelling gradients of multilayers mediate directional cell migration

Lulu Han, Zhengwei Mao, Jindan Wu, Yang Guo, Tanchen Ren, Changyou Gao*

MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Department of Polymer Science and Engineering, Zhejiang University, Hangzhou 310027, China. cygao@zju.edu.cn

INTRODUCTION

The cell migration plays a crucial role in a variety of physiological and pathological processes¹. The cell's compass is governed by various directional cues, such as soluble chemoattractants (chemotaxis), surface-attached molecules (haptotaxis), and mechanical cues (durotaxis)². So far the surfaces with chemical and physical gradients have been prepared and their influences on the cell migration have attracted increasing attention. Among the various surface engineering methods, the layer-by-layer (LBL) assembly can diversely tailor the substrate properties and is particularly suitable to modify the biomaterials surface³. It is found recently that the chitosan/heparin gradient multilayers pre-adsorbed with fibronectin are able to guide MG-63 osteoblast-like cells' movement⁴.

EXPERIMENTAL METHODS

To generate the gradient multilayers the substrate assembled with the poly(sodium 4-styrenesulfonate) (PSS)/poly(diallyldimethylammonium) chloride (PDADMAC) multilayers was vertically immersed into the 3-5 M NaCl gradient solution for 2 h, and was then washed with water and dried under a smooth stream of N₂. The smooth muscle cells (SMCs) were plated on the salt etched multilayers at low ($5 \times 10^3/\text{cm}^2$) and high ($1.5 \times 10^4/\text{cm}^2$) seeding densities, respectively. Approximately 12 h after the cell seeding, the cell migration was *in situ* recorded using a time-lapse phase-contrast microscope

RESULTS AND DISCUSSION

The gradient nature and physicochemical properties were characterized by X-ray photoelectron spectroscopy and ellipsometry. Compared to the random migration with a lower rate at a smaller cell-seeding density, the vascular smooth muscle cells migrated directionally to the low hydration side at an appropriate cell-seeding density ($1.5 \times 10^4/\text{cm}^2$) under the assistance of cell-cell interactions. The cell migration rates on the gradient surface were significantly larger than those on the corresponding uniform surfaces etched by salt solutions of the same concentrations (Figure 1). At the optimal condition, 95% of the cells moved toward the lower swelling region with a rate of $53 \pm 10 \mu\text{m/h}$, which are the best results achieved so far in this field. Relative cell adherent strength and focal adhesion formation were studied to unveil the intrinsic mechanism of the gradient

multilayers on the cell migration. It was found that both the gradient cues and cell-cell contact have major influences on the directional cell migration⁵.

Figure 1. Cell migration rate on the uniform (left group) and gradient (right group) multilayers as a function of gradient position. Data were averaged from ≥ 15 cells. * indicates significant difference at $p < 0.05$.

CONCLUSION

The gradient PSS/PDADMAC PEMs with a gradually increasing swelling ratio were prepared. For the first time it was found that the directional migration of SMCs were guided by both the gradient physical cue and the cell-seeding density. The work establishes an effective method to prepare the gradient biomaterials with unique functions to guide the directional cell migration, providing the possibility to regenerate tissues and organs in a controlled time and spatial scale.

INTRODUCTION

In view of the growing interest in using graphene-based materials (GBMs) in medical applications, it is relevant to evaluate their biocompatibility, which depends on intrinsic physical-chemical properties (*e.g.* size, hydrophilicity). GBMs may induce cell death by generation of reactive oxygen species (ROS) or direct damage on cell membrane by a blade like action of GBMs sharp edges.¹ In this work, the biocompatibility of graphene nanoplatelets (GNP) with different dimensions and oxidation is studied. The work is focused in understanding mechanisms behind GBMs *in vitro* toxicity, and identifying how to minimize those effects, in order to allow uses in biomedical applications.

EXPERIMENTAL METHODS

Graphene nanoplatelets grades M-5 (GNP-M) and C-750 (GNP-C), were acquired from XG Sciences (Lansing, USA), with the following characteristics: GNP-M - thickness 6-8 nm, length 5 μm , surface area 120-150 m^2g^{-1} ; GNP-C - thickness <2 nm, length 1-2 μm , surface area 750 m^2g^{-1} . GNP-M was oxidized by modified Hummers method. The designations GNP-M-ox-1:3 and 1:6 represent the ratio GNP-M/KMnO₄ used. Scanning electron microscopy (SEM) was used to observe morphology. X-ray photoelectron spectroscopy (XPS) was used to determine chemical composition. Raman spectroscopy was used to evaluate the degree of oxidation. Thermogravimetric analysis (TGA) was employed for quantifying the mass loss by early degradation of oxidized materials. Live/Dead assay was performed by staining dead HFF-1 cells with propidium iodide (PI), live cells with calcein and the total number of cells with hoechst 33342. Cell death (%) was calculated as the number of cells stained with PI / number of cells stained with hoechst * 100. Transmission electron microscopy (TEM) images were obtained to evaluate GNP/cell interactions. Reactive oxygen species (ROS) were quantified using the indicator CM-H₂DCFH-DA which is converted indirectly by ROS to highly fluorescent DCF, detected in the fluorimeter.

RESULTS AND DISCUSSION

From SEM images (not shown) it was observed that GNP-C has lower diameter (1 μm) than GNP-M (5 μm). XPS and TGA results show that O at.% increases about 20% for both oxidized materials, comparing to GNP-M. Moreover, Raman spectroscopy reveals that oxidation of GNP-M-ox-1:6 is more homogeneous than for GNP-M-ox-1:3. Oxidized platelets present similar size, but less sharp edges (SEM). Hemolysis for all GBMs, was

below 3%, up to concentrations of 500 $\mu\text{g mL}^{-1}$ at 3h. Live/Dead assay shows that cell death is low (<13%) for all materials in concentrations between 1-100 $\mu\text{g mL}^{-1}$. GNP-M (cell death = 13%) is more toxic than GNP-C (6%), for a concentration of 100 $\mu\text{g mL}^{-1}$ at 72h. Also, GNP-M-ox-1:3 (9%) presents similar toxicity to GNP-M and GNP-M-ox-1:6 (1%) toxicity is significantly lower than GNP-M. The fact that GNP-M-ox-1:6 is homogeneously oxidized, presenting less sharp edges than GNP-M, suggests that less physical damages are induced, explaining lower number of dead cells. These results are in agreement with those obtained in resazurin assay (not shown). TEM images (not shown) show that GNP-M interacts with cell membrane and in few cases particles are found inside plasma membrane. GNP-C, which is smaller, is often spread in cytoplasm, interacting with organelles. Also, several vesicles are often found along cytoplasm and in some cases next to GNP-C particles. No damages are observed in cell membranes. GNP-C (50 $\mu\text{g mL}^{-1}$, 1h) increases ROS production by 4.4 fold comparing with negative control PBS 0.01M, while GNP-M only increases 1.5 fold. GNP-M-ox-1:3 present a slightly higher value of 2.1 and GNP-M-ox-1:6 of 1.6. These results indicate that size is the main factor leading to ROS formation, because smaller GNP-C penetrates cell membrane more easily than GNP-M and M-ox-1:3 and 1:6, inducing higher intracellular ROS formation.

CONCLUSION

GNP-C, due to presenting smaller size, enters cells and induces ROS production. This leads to 6% cell death, for a concentration of 100 $\mu\text{g mL}^{-1}$ at 72h. GNP-M, with bigger size and sharp edges, rarely enters cells but induces physical damages on cell membranes. The presence of GNP-M is more toxic (cell death = 13%) to cells. However, complete oxidation of this material (GNP-ox-1:6) prevents toxicity (cell death = 1%). It occurs because platelets present a more wrinkled shape, with smoother edges, which prevents physical damages. In most cases cell death increases with concentration. However, it is low for all materials and concentrations (1-100 $\mu\text{g mL}^{-1}$) until 72h. Hemolysis for all materials, was below 3%, up to concentrations of 500 $\mu\text{g mL}^{-1}$ at 3h.

lipires@ineb.up.pt

INTRODUCTION

Spinal cord injury (SCI) is characterized by the interruption of axonal pathways and the activation of inhibitory mechanisms that convert the lesion site into a non-permissive substrate for axonal re-growth [1]. It is well accepted that to promote regeneration in such an adverse environment, a multi-target strategy will be needed [2]. Ibuprofen is a non-steroidal anti-inflammatory drug that showed to support axonal growth in inhibitory substrates, being also able to induce an improved regeneration after SCI *in vivo* [3]. Its effect has been associated with the inhibition of RhoA activation [3]. In this study we describe the development of a scaffold based on poly(trimethylene carbonate-co-ε-caprolactone) [P(TMC-CL)] that provides physical guidance cues, via longitudinally aligned electrospun fibres, while serving as a platform for the delivery of ibuprofen.

EXPERIMENTAL METHODS

Bilayer scaffolds were prepared using P(TMC-CL) (11 mol% of TMC, Mn= 8.2x10⁴, Mw/Mn= 1.6). The outer layer was composed by a solvent cast film prepared from a 6% (w/v) P(TMC-CL) solution in CH₂Cl₂. Electrospun fibres were collected onto the solvent cast film fixed to a rotating drum (3000 rpm). A 10% (w/v) P(TMC-CL) solution in CH₂Cl₂ and DMF mixture (3:1) was applied. 5% (w/w of polymer) of ibuprofen was added in solutions to prepare ibuprofen-loaded scaffolds. To assess ibuprofen release (HPLC), scaffolds were incubated at 37°C (120 rpm) in phosphate buffered saline, refreshed at each evaluation time point.

ND7/23 cells were sub-cultured in supplemented DMEM and differentiated for 2 days. RhoA activation was induced by treating starved cells with lysophosphatidic acid (45 μM, 10 minutes). The effect of ibuprofen on RhoA activation was analysed by pre-treating ND7/23 cells with the drug (500 μM) in its soluble form or with extracts from P(TMC-CL) bilayer scaffolds. The activated form of RhoA assessed in a pull down assay.

Bilayer scaffolds (6x5 mm) were tested *in vivo* in a dorsal hemisection rat model of SCI. Three groups were included: (A) lesion, (B) P(TMC-CL) scaffolds and (C) ibuprofen-loaded P(TMC-CL) scaffold. Tissues were collected 5 days after injury and snap frozen for biochemical assays or fixed for histological analysis. Tissues were cryosectioned and immunolabelled for glial fibrillary acidic protein (GFAP).

RESULTS AND DISCUSSION

Bilayer P(TMC-CL) scaffolds were prepared. In the fibrous layer of the scaffolds, > 90% of the fibres were found to be oriented relative to the longitudinal axis. Fibre alignment was not significantly affected by the presence of ibuprofen. Fibre mean diameter was found to be 0.661 and 0.646 μm for non-loaded and ibuprofen-loaded fibres, respectively (Fig.1). Ibuprofen release in sink conditions was found to occur in the first 24hrs of incubation (Fig.1E).

Fig.1. SEM micrographs of bilayer P(TMC-CL) (A,B) non-loaded and (C-D) ibuprofen loaded scaffolds. (E) Cumulative release of ibuprofen.

When ND7/23 cells were pre-treated with extracts obtained from ibuprofen loaded scaffolds, LPA-induced RhoA activation was significantly reduced indicating that the released drug retains its bioactivity as inhibitor of the RhoA pathway in a neuronal-like cell line.

The implantation of the P(TMC-CL) scaffolds did not compromise animal survival. A detailed histological characterization of the tissues is ongoing, but the preliminary analysis of the tissue cryosections suggests that the number of astrocytes at the lesion site is reduced when ibuprofen-loaded scaffolds were implanted.

CONCLUSION

Bilayer ibuprofen-loaded P(TMC-CL) scaffolds were successfully prepared. It was demonstrated that ibuprofen released from the scaffolds can have an active role limiting RhoA activation *in vitro*, in a neuronal-like cell line.

The assessment of the effect of ibuprofen release from the P(TMC-CL) scaffolds on reducing RhoA activation upon a spinal cord lesion is currently underway.

INTRODUCTION

The host response to foreign materials typically progresses under the form of foreign body reaction (FBR) associating macrophages and multinucleated giant cells (MGC)¹ and often results in the failure of implanted devices by several mechanisms, including fibrotic encapsulation. Understanding signals that control the FBR therefore represents an important issue. Platelets are activated on implanted biomaterials with subsequent release of a range of inflammatory mediators, among which CD154. Platelets are the main source of CD154 in the body and mononuclear phagocytes express CD40, the CD154 receptor, which signals macrophages mainly towards a pro-inflammatory phenotype². We asked the question whether CD154 plays a role in the FBR.

EXPERIMENTAL METHODS

To study the progression of the FBR, a model of absorbable suture graft was implemented in mice treated with the anti-platelet agent clopidogrel, which inhibits CD154 release by activated platelets, and in CD154KO mice. In these models, a FBR is triggered in response to the grafted biomaterial.

Male Balb/c CD154KO mice were generated as reported³. Bundles of absorbable polyglactin 910 suture threads were subcutaneously implanted in mouse backs. Macrophages were obtained by *in vitro* differentiation of peripheral blood monocytes; MGC were obtained through IL-4-mediated macrophage fusion. Phagocytosis assays and ELISA were performed using commercial kits. Immunofluorescence, histology/immunohistochemistry, real time RT-PCR, flow cytometry and biochemical measurements were performed according to standard protocols.

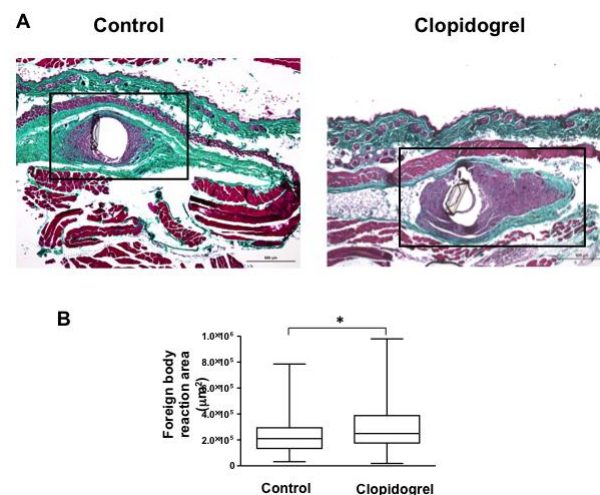

Data are presented as means \pm SD. Statistical comparisons between groups were performed using the Wilcoxon signed-rank test. $P < 0.05$ was taken to imply statistical significance.

RESULTS AND DISCUSSION

Suture bundle clearance occurred at 8 to 10 weeks post implantation. FBR areas were significantly larger at week 10 in WT mice treated with the platelet inhibitor clopidogrel, which inhibits CD154 release by activated platelets (average 30 versus 21 μm^2 , $p < 0.0001$, in treated and untreated mice, respectively) indicating delayed clearance.

We then studied CD154 role. In both WT and CD154KO mice, macrophages and MGCs expressing the F4/80 antigen were similarly organized as a FBR. Delayed clearance was also observed in CD154KO mice (average 31 versus 23 μm^2 , $p = 0.03$, in CD154KO and WT mice, respectively).

These results suggested that CD154 deficiency was associated with FBR impediment.

“Platelet activation inhibition leads to a delayed resolution of the FBR. (A): representative Masson's trichrome-stained tissue sections at week 10; squares highlight the foreign body reaction in subcutaneous tissues. (B): quantification of the granulomatous reaction area in control and clopidogrel-treated mice ((* $p < 0.0001$)).”

We studied potential mechanisms *in vitro*. CD154 may interfere with macrophage recruitment, adhesion to foreign material, activation and fusion. Macrophages and MGC expressed CD40. There were no differences in macrophage or MGC recruitment and CD154 had no effect on macrophage fusion. However, CD154 stimulated the phagocytosis of opsonized red cells by macrophages and drove macrophages polarization into a M1 phenotype.

CONCLUSION

Our studies suggest that platelets may play a role in the FBR to biomaterials through the release of CD154. The inhibition of CD40/CD154 interaction may represent a novel strategy to limit the FBR progression.

The mechanical behavior and biocompatibility of polymer blends for Patent Ductus Arteriosus (PDA) occlusion device

Ying Ying Huang^{1*}, Yee Shan Wong¹, and Subbu S. Venkatraman¹

¹School of Materials Science and Engineering, Nanyang Technological University, Singapore
yingyinghuang@ntu.edu.sg

INTRODUCTION

Patent Ductus Arteriosus (PDA) is a cardiovascular defect that occurs in 1 out of every 2000 births¹, and if left untreated, may lead to severe cardiovascular problems. Although the incidence rates associated with current permanent PDA devices are low, the complication is usually serious enough to warrant immediate surgical retrieval^{2,3}. The purpose of this study was to develop a fully degradable occluder for the closure of PDA, that can be deployed percutaneously without open-heart surgery.

EXPERIMENTAL METHODS

For percutaneous deployment, both elasticity and sufficient mechanical strength are required of the device components. As this combination of properties is not achievable with currently-available homo- or copolymers, blends of biodegradable poly (ϵ -caprolactone) (PCL) and poly (L-lactide-co- ϵ -caprolactone) (PLC) with various compositions were studied as the potential material for the PDA occlusion device. Microstructures of this blend were characterized by differential scanning calorimetry (DSC) and tensile tests. Then, suitable blends were selected to fabricate a prototype of PDA occluder and its in vitro performance, in term of device recovery (from its sheathed configuration), biodegradation rate and blood compatibility, was evaluated. Finally, an artificial PDA conduit was created in a pig model, the feasibility and 1 month follow up study were carried out.

All data are presented as mean \pm standard deviation (SD). Statistical analysis was carried out using one way ANOVA and the values are considered significantly different when $p < 0.05$.

RESULTS AND DISCUSSION

DSC results demonstrated the immiscibility between PCL and its copolymer PLC. Furthermore, the mechanical properties, i.e. elastic modulus and strain recovery, of the blends could be largely tailored by changing the continuous phase component, as shown in Figure 1. Based on the mechanical tests, we selected PLC, PCL/PLC30 and PCL/B as the materials for the umbrella, the spoke & anchoring arm, and the stem of PDA occlusion device respectively. The in vitro recovery test based on the assembled PDA occlusion device showed that more than 70% recovery is obtained within 2 - 3 minutes, which is an acceptable closure time period in vivo. In terms of the biodegradation, the earliest mass loss was observed at month 2 and the PDA occlusion device started to disintegrate within 5 - 6 months. Furthermore, the leukocyte and platelet count results showed no adverse effect of the chosen materials in this study, and the inflammatory response and fibrosis capsule formation results showed comparable

performance to the HDPE control. Finally, the in vivo feasibility study demonstrated that the device was able to recover within 2-3 minutes in vivo for immediate closure of the artificial PDA conduit, and 1 month follow-up results confirmed that there was no leakage across the defect and that the device was completely covered by tissue, as shown in Figure 2.

Fig. 1. Dependence of modulus (E) and strain recovery (R) on PLC content.

Fig. 2. (a) Photograph of the surgical created PDA conduit, (b) Angiogram of the created PDA conduit (red line), (c) Angiogram of post-implantation PDA occlusion device, (d) Angiogram of post-implantation PDA device, (e) Digital subtraction angiograms of 1 month post-implantation PDA device, and (f) Gross macroscopic examination of PDA device.

CONCLUSION

Thus, a novel prototype for PDA occlusion that is fully degradable has been developed to overcome the limitations of the currently used metal/fabric devices.

Nanofiber-based biomaterials used to direct cellular responses associated with epithelial-mesenchymal transition

Raquel C. Barros^{1*}, Edith Gelens², Menno de Jong², Roel Kuijer¹, Theo G. van Kooten¹

^{1*}Department of Biomedical Engineering, University Medical Center Groningen (UMCG), University of Groningen, Hanzplein 1, 9713 GZ Groningen, The Netherlands, r.s.da.cruz.barros@umcg.nl

² Nano Fiber Matrices B.V. (Nano-FM), Zernikepark 6-8, 9747 AN, Groningen, The Netherlands

INTRODUCTION

Lens epithelial cells (LEC) change their phenotype to mesenchymal cells in a process called Epithelial Mesenchymal Transition (EMT)¹. This process is associated with fibrotic tissue formation, which is the basis of posterior capsule opacification (PCO) after cataract surgery². Cataracts are treated surgically by replacement of the lens nucleus with an intra-ocular lens (IOL). This EMT starts with the inflammatory response due to surgery and continue over a time due to the presence of IOL in the interior of the lens³. Different methods have been approached to avoid PCO, from the optimization of surgery to the use of drugs and new biomaterials for the intra-ocular lens (IOL). None of these approaches totally avoid total PCO. The purpose of this project is to study self-assembled nanofiber systems for their potential to avoid EMT and consequently avoid secondary PCO.

EXPERIMENTAL METHODS

Self-assemble nanofibers with different chemistry, hydrophobicity and morphology in the presence of LEC, human skin fibroblasts (HskF) and human mesenchymal stem cells (hMSC) were studied. Based on 2D and 3D analyses of cellular metabolic activity, real-time PCR and immunohistochemistry we extrapolate, by comparing LEC with HskF and hMSC, which nanofibers should be the best candidate to avoid and/or prevent EMT.

RESULTS AND DISCUSSION

Exceedingly different cell behavior in these different nanofibers was found. Conditions for cell proliferation and for cell repellency were created (Fig.1). Associated with these results nanofibers linked with peptides showed, in addition to different cell behavior, a high decrease in fibrotic markers.

Figure 1: LEC in 2D contact with TCPS (A) and three different nanofibers (B, C and D). Large cellular proliferation on B); repellence of cells to the nanofiber with cell death (not showed) on C) and very low proliferation on D). Blue-DAPI; Red-Phalloidin (TRITC); Green- Fibronectin (FITC) Scale bar=75µm

CONCLUSION

In this study we found biologically active nanofibers to be able to reduce EMT markers. It shows a great potential of the use of these nanofibers in future clinical application.

Incorporation of RANKL Promotes Osteoclast Formation and Osteoclast Activity on β -TCP Ceramics

J. Choy^{1,2}, C.E. Albers², K.A. Siebenrock², S. Dolder¹, W. Hofstetter¹, F.M. Klenke^{1,2}

¹Department of Clinical Research, University of Bern, Switzerland

²Department of Orthopaedic Surgery, Bern University Hospital, Switzerland, john.choy@dkf.unibe.ch

INTRODUCTION

β -tricalcium phosphate (β -TCP) ceramics are approved for the repair of osseous defects¹. In large defects, however, the substitution of the material by authentic bone is inadequate to provide sufficient long-term mechanical stability². We aimed to develop composites of β -TCP ceramics and receptor activator of nuclear factor κ -B ligand (RANKL) to enhance the formation of osteoclasts³ and promote cell mediated turnover of the β -TCP ceramics.

EXPERIMENTAL METHODS

RANKL (62.5 μ g in 2.5 ml coating solution) was immobilized on porous β -TCP ceramic cylinders (h: 2 mm, d: 14 mm, pore size 150-200 μ m, porosity 75 ± 5 %) by (i) superficial adsorption for passive short-term release and (ii) co-precipitation with calcium phosphate (CaP), resulting in incorporation of the protein into a crystalline layer of CaP and in a cell-mediated long-term release⁴. Immobilization of bovine serum albumin (BSA, 12.5 μ g in 2.5 ml) served as negative control.

Murine osteoclast precursors were seeded onto the ceramics in medium containing colony-stimulating factor 1 (CSF-1) at 30 ng/ml. Osteoprotegerin (OPG) was added in one group as RANKL inhibitor. After 15 days, osteoclasts were visualized by staining for tartrate-resistant acid phosphatase (TRAP) and TRAP activity was quantified in cell lysates. Levels of transcripts encoding the osteoclast products calcitonin receptor, cathepsin K and NHA2 were quantified by real-time PCR. The activity of newly formed osteoclasts was evaluated by means of a CaP resorption assay: murine osteoclasts were seeded onto a thin crystalline CaP layer with RANKL incorporated. After 48 hours, the resorbed area of the CaP was visualized by von Kossa staining and quantified using ImageJ 1.46r for Windows.

Data are presented as the mean \pm SD from one out of three individual experiments (n = 6). Data were analyzed by one-way ANOVA and Sidak post-hoc test using SPSS[®] V19.0 for Mac.

RESULTS AND DISCUSSION

Figure 1. TRAP activity in cultures of osteoclast precursors seeded onto β -TCP ceramics after a culture period of 15 days. * $p < 0.001$ vs. co-precipitated RANKL and exogenous CSF-1; † $p < 0.001$ vs. coated BSA (co-precipitated) and exogenous CSF-1 + RANKL; ‡ $p < 0.001$ vs. coated BSA (superficially adsorbed) and exogenous CSF-1 + RANKL.

Figure 2. Resorptive activity of osteoclasts grown on crystalline CaP. 5 μ g/ml BSA or 25 μ g/ml RANKL respectively were incorporated into the crystalline CaP layer by protein co-precipitation (coating volume 0.5 ml). Additional treatment with 20 ng/ml and 100 ng/ml RANKL was performed in all groups. * $p < 0.05$ vs. 5 μ g/ml BSA-CaP, 0 ng/ml RANKL; † $p < 0.01$ vs. 25 μ g/ml RANKL-CaP, 0 ng/ml RANKL; ‡ $p < 0.001$ vs. 25 μ g/ml RANKL-CaP, 100 ng/ml RANKL.

Incorporation of RANKL (long-term release) induced the formation of TRAP⁺ (Fig.1) osteoclasts expressing the osteoclast markers calcitonin receptor, cathepsin K, and NHA2. Co-precipitated RANKL was effective in supporting the development of active, resorbing osteoclasts and promoted their resorptive activity. Additional exogenous RANKL enhanced osteoclast activity dose-dependently (Fig. 2). Adsorption of RANKL (short-term release) did not induce osteoclast formation showing that a long-term release system of RANKL is required to support osteoclast formation.

CONCLUSION

The technique by which RANKL is immobilized on the CaP ceramics plays a key role in the support of osteoclast development and activation. With the co-precipitation technique, the differentiation of osteoclasts is initiated due to a residual passive release of incorporated RANKL. Once formed, osteoclasts mediate the release of RANKL, thereby perpetuating their differentiation and activation, which results in a stimulation of cell-mediated CaP resorption.

INTRODUCTION

The amorphous calcium phosphate is pointed in the literature as a precursor stage of the hydroxyapatite in bone tissue formation¹. Similar to a cotton swab, a set of micrometer fibers of amorphous calcium phosphate graft is obtained by Hager-Rosengarth process². The advantage of the shape as fiber makes possible the graft fits any configuration of defect, combining hemostatic function to its main characteristic, that is, be biocompatible, osseointegrated, resorbable and assisting in bone remodeling. The fibers presented high-purity composition, non-cytotoxicity, resorbable in months and osteo-conductive as any other graft of amorphous calcium phosphate³⁻⁵. It's rare to find scientific literature regarding ACP fibers.

EXPERIMENTAL METHODS

The starting material is obtained by hydrothermal reaction of CaO and P₂O₅ in a Ca/P > 1. The material is dried and ground and then heated to 1350 Celsius when flows into the rotational base of the Hager-Rosengarth machine forming the fibers with diameters ranging from 5 µm to 50 µm that can be seen in Figure1.

Figure1. ACP fibers.

RESULTS AND DISCUSSION

The non-crystalline condition of the obtained fibers is confirmed by X-ray diffraction as shown in Figure 2.

Figure 2. Fiber X-ray diffraction spectrum.

The ACP fibers show biocompatibility by means of the cellular viability curve above IC₅₀% line and are considered non-cytotoxic (Figure 3).

Figure 3. Cytotoxicity test of ACP fibers.

Two tests "in vivo" were performed: (a) in rat alveolus to check newly formed collagenous matrix, and (b) in human alveolus to prove the bone-conduction. Figures 4 and 5 show the images of these proofs respectively.

Figure 4. Alveolus bone (AB); newly formed bone (NF); osteoid tissue (OT).

Figure 5. Newly formed bone (NF); fiber (F).

CONCLUSION

1. ACP fibers as a graft, result in good vascular infiltration, bone formation and consistent activities of deposit and remodeling. (Fig. 4).
2. Remaining fibers flanking the newly formed tissue, guide the deposition of bone matrix layers (Fig. 5).

EPA-Coated Implants Promote Osteoconduction in White New Zealand Rabbits

Ammar Mustafa^{1,2,3}, Christie Lung, Jukka Matinlinna³

¹ISF Consultancy Hospital (Lekhwiya)/Doha, Qatar

²Dental Materials Science/Faculty of dentistry, IIU-Malaysia

³Dental Materials Science/Faculty of dentistry, Hong University, China, drammar71@gmail.com

INTRODUCTION

The use of dental implant fixture coating based on an organic acid, such as eicosapentaenoic acid (EPA) with an ability of osteoconduction could be a promising treatment for some challenging cases of patients with a history of radiotherapy or patients with diabetes, osteoporosis, and other patients with poor wound healing. Biocompatibility and adequate biomechanical properties are the main requirements in determining the clinical success of any type of dental implant¹.

Eicosapentaenoic acid (EPA) is an omega-3 highly polyunsaturated fatty acid (n-3-PUFA) has been detected to provides advantageous effects on bone remodelling². Ultimately, n-3-PUFA, including EPA, has been verified to positively influence bone health and skeletal biology^{3,4}. Hypothesis was set that EPA-coated dental implants might 1) increase the osteoconduction process, verified by a significant difference between the test and control side of the same implant by testing the axial pull-out test of the implants. 2) increase the rate of new bone formation on the implant surface verified by Cone Beam Computed Tomography (CBCT) and X-ray findings.

EXPERIMENTAL METHODS

The current animal study was approved by the ethical committee of the University according to the regulations of (IACUC).

Twenty four planar titanium plates (5mmX5mmX1mm) were surgically fixed half way into the mandibular bone of twelve white New Zealand rabbits. The rabbits were randomly assigned into three study groups (n=4). The planar implants were coated with EPA on one side and were highly polished on the other side.

CBCT was used to inspect the bone-implant interface assessing the density and the new bone formation on the exposed part of the implant. The specimens were analysed by radiographs to the implants and the neighbouring bone structure to analyse osteoconductive bone formation at the coated side and to compare it with the bone at the control side. Axial pull-out tests were performed to the specimens to test osseointegration (Figure1).

Non-parametric Kruskal-Wallis test and multiple time series comparisons Friedman's test were employed. Both analyses were set at significance level of $p < 0.05$ to compare differences in the amount of implant covered by new bone formation between the coated and the not coated implant surfaces in different time intervals. Osseointegration was analysed by comparing the amount of force, as an action of axial pull-out test, after periods of 4, 8, and 12 weeks respectively.

RESULTS AND DISCUSSION

By using CBCT and radiographs, osteoconductive bone formation was estimated at the coated test side of Ti

compared to the polished non-coated side four weeks postoperatively (Figures 2-4). Statistical results showed significant difference after 8 weeks ($p=0.05$) on the EPA-coated side compared to the non-coated side. Also, statistical analyses revealed a significant difference ($p = 0.01$) between the amount of pull-out force after 8 and 12 weeks, compared to 4 weeks.

In the current experiments, the set up was designed to investigate the outcome of coating dental implants with omega-3 fatty acid on osteoconduction after fixation in the mandibles of rabbits. It has been found that osteoconduction was significantly obvious after 4 weeks of the surgery. Therefore EPA affects osteoconduction and functions as a growth factor in vivo. EPA coated titanium implants in rabbits were found to enhance osteoconduction at the bone-implant interface. This finding might be considered to point at an increased osseointegration capacity of EPA coated implants.

CONCLUSION

As titanium implant fixture coating, EPA coating seems to enhance the anchorage between bone and external fixation of the Ti prosthesis. EPA-based implant coating stimulates osteoconduction processes in rabbits. This coating might increase bone healing processes after implant surgery.

INTRODUCTION

In bone regeneration, Si-based calcium phosphate glasses (Bioglasses[®]) have been widely used since the 70s¹. However, they dissolve slowly because of their high amount of Si ($\text{SiO}_2 > 45\%$). Recently, our group has found that calcium ions released by the degradation of glasses in which the job of silicon is done by just 5% of TiO_2 are effective angiogenic promoters, because of their stimulation of a cell-membrane calcium sensing receptor (CaSR)². Based on this, other focused tests on angiogenesis have found that Bioglasses[®] also have the potential to be angiogenic promoters even with high contents of silicon (80%); however, their slow degradation is still a problem, as the levels of silicon cannot be decreased any lower than 45%³. In this work, we propose a new generation of hybrid organically modified glasses (ormoglasses) that permit a reduction of the Si content, therefore speeding up the degradation process. Using electrospinning as an accurate way of mimicking the extracellular matrix (ECM), we successfully produced hybrid fibrous mats with three different contents of Si (40% PCLS40, 52% PCLS52 and 70% PCLS70) – and thus three different calcium ion release rates – using an ormoglass-polycaprolactone blend.

EXPERIMENTAL METHODS

Sol-gel method was selected to develop the organometallic network by means of alkoxide precursors in an inert atmosphere through a partial hydrolysis and condensation process; ϵ -polycaprolactone (PCL) was the used biodegradable polymer. The aim was to join both domains at a nanometric level to obtain a tuned ion-agent release order to act as cell homing and enhance osteogenesis. Special attention was paid in the bulk, interface and degradation properties, evaluated by FE-SEM, EDS, DSC, TGA, tensile-strain assays, pH and Ca^{2+} release evaluation, contact angle measurements, AFM, ζ -potential. We also performed cell proliferation assays, ALP, western blotting analysis and PCR analysis. We performed *in vivo* subcutaneous tests to evaluate the osteogenic potential.

RESULTS AND DISCUSSION

The production of different blends of ORMOLASS/PCL with different Si contents was successful. Tensile-strain assays showed that the more Si content, the higher the Young's modulus. TGA analysis revealed that the inorganic content increase with the decrease of silicon. DSC analysis showed PCL-S40 fibers had the most crystalline structure (27.6%) compared with the rest of the blends. AFM showed that the lower the silicon content, the higher the stiffness, in contrast with tensile-strain assays. ζ -potential plots showed a significant increase of the surface charge for PCL-S40 com-

pared with the rest of the fibrous scaffolds. It was also the sample with a higher release rate of calcium and the most constant sustained decrease at higher time points. PCL-S40 showed the best cell-material interaction and the most enhanced MC3T3-E1 cells differentiation over the rest. No inflammatory signs and material related complications were observed. Surprisingly, numerous vessels were observed over the whole area of the mats. PCL-S40 showed the highest number of new blood vessels. Biological results not only confirm the osteogenic potential of the composition with less Si content, but also suggest a better angiogenic effect. The higher and sustained release of Ca^{2+} to the media plays a key role in the promotion of blood vessel formation.

Figure 1. AFM plots showing the topography (a) and DMT modulus map (b). Staining optic microscopy images for vWF of PCL-S40 (c) and its quantification (d) at x200.

CONCLUSION

Material and biological characterization suggested that compositions of organic/inorganic hybrid materials with a Si content equivalent to 40%, which were also those that released more calcium, were osteogenic, with a greater ability to form blood vessels. These results suggest that Si-based ormoglasses can be considered an efficient tool for Ca^{2+} release modulation, which could play a key role in the osteo- and angiogenic promoting process.

The Wear and Biological Activity of Antioxidant UHMWPEs in Total Hip Replacements

Nic Gowland¹, Sophie Williams¹, John Fisher¹, Joanne L Tipper¹

¹Institute of Medical & Biological Engineering, University of Leeds, Leeds, LS2 9JT
bs07n3g@leeds.ac.uk

INTRODUCTION

Oxidative degradation of highly irradiated UHMWPE has been shown to reduce the lifespan of UHMWPE in total hip replacements [1]. Antioxidant UHMWPE was developed to reduce oxidation in low-wearing highly irradiated UHMWPE, with vitamin E enhanced UHMWPE gaining FDA approval in 2007 and a hindered phenol antioxidant (AOX) in development.

This study investigated the wear of antioxidant UHMWPE (vitamin E, AOX) compared to virgin and highly crosslinked UHMWPE and also the biological response to antioxidant materials. Sterile wear particles were incubated with primary macrophages to determine the volume of particles required to stimulate a cytokine response. The cytokine response to vitamin E and non-vitamin E highly crosslinked UHMWPE is to be investigated.

Finally, the study investigated the effect of vitamin E enhanced UHMWPE on the production of reactive oxygen species (ROS), thought to be an important aspect of the role UHMWPE plays in stimulating a cytokine response from cells, and therefore vital to osteolysis.

EXPERIMENTAL METHODS

UHMWPE materials – 1050; 1050 virgin, Marathon (5MRad), HXL (10MRad), Vit E, Vit E 5MRad, Vit E 10MRad: 1020; 1020 virgin, AOX, AOX 8.5MRad. Wear testing was conducted using a 6 station pin-on-plate wear rig, with 10mm pins articulating against a smooth CoCr plates, using kinematics representative of the hip joint [2]. Wear was determined gravimetrically and converted into a wear factor.

For particle:cell culture, sterile particles were suspended in agarose gel and PBMCs isolated from human blood were seeded on to the gel. Cells/particles were incubated for 24 hours at 37°C, 5% CO₂. Cell viability was determined using ATP Lite assay; ELISA was performed to determine TNF-α production.

For ROS study, PBMCs were incubated directly with sterile particles for 48 hours, after which Image-IT Live staining was performed for ROS and Hoechst was used to stain the nucleus.

RESULTS AND DISCUSSION

Wear factors for UHMWPE materials are shown in fig 1. Vitamin E or AOX antioxidants had no significant effect on the wear factor. Increasing irradiation dose alone reduced the wear factor, with highly irradiated materials showing the lowest wear factors for each category.

Figure 1 – Wear factor of different UHMWPE materials. Green shows non-antioxidant UHMWPE; orange shows vitamin E UHMWPE; blue shows GUR 1020 UHMWPE, including AOX enhanced. Error bars show 95% confidence level.

The cell: particle studies showed that PBMCs incubated with HXL particles at 100µm³ did not significantly stimulate TNF-α release in 24 hours. This assay was therefore optimised and it was found that incubation only at 600µm³ per cell stimulated a significant TNF-α release from PBMCs (fig 2). Particles containing vitamin E will therefore be seeded at 600 µm³ per cell.

Figure 2 – TNF-α release from PBMCs incubated with 1050 HXL UHMWPE for 24 hours. Error bars show 95% confidence level.

Finally, an investigation into the production of ROS in PBMCs incubated with HXL and Vit E 10 particles was carried out. HXL particles stimulated the production of ROS in the cytoplasm of PBMCs. However, Vit E 10 particles did not stimulate the same intensity of ROS in cells, with results comparable to the cells only control.

CONCLUSION

The addition of an antioxidant to UHMWPE had no adverse effects on the wear factor of the material, where increased irradiation dose alone significantly improved the wear resistance of the material. However, the addition of vitamin E to highly crosslinked UHMWPE appears to reduce the production of ROS, suggesting vitamin E is available to cells and has the potential to reduce inflammation and osteolysis.

INTRODUCTION

Strategies for bone tissue engineering and regeneration rely on bioactive scaffolds to mimic the natural extracellular matrix and act as templates onto which cells attach, multiply, migrate and function.¹ The constituent and structure of bone repairing scaffolds need to be biocompatible, biodegradable during tissue regeneration process, structurally similar to bone, and with some degree of mechanical strength.²

In this work, we investigated a porous three-dimensional (3D) hybrid chitosan (CHI)/hyaluronic acid (HA) scaffold suitable for tissue engineering applications. Cell colonization was studied using Wharton's Jelly stem cells (WJ-SCs) which are considered as primitive stem cell much more proliferative, immunosuppressive, and even therapeutically active than adult stem cells.

EXPERIMENTAL METHODS

CHI (from Sigma, France) was dissolved in 0.1M acetic acid at 0.2 g/L. The solution was neutralized by the addition of β -glycerolphosphate (β -GP) at 4%. HA (from Soliance, France) was added with a concentration of 0.6 g/L. The two solutions were mixed at a ratio of 3:1 (v/v). Genipin solution was incorporated into the mixture to crosslink CHI/HA solution at 37°C for a night. Then, they were freeze-dried to make 3D scaffolds.

The porosity, pore size, water uptake ability, and structural compounds were investigated. Cellular compatibility and proliferation were highlighted through LDH and MTS assay respectively.

RESULTS AND DISCUSSION

Formation of 3D porous scaffold was demonstrated by scanning electron microscopy (SEM) (Figure 1) and confocal microscopy. Adding β -glycerolphosphate to the mixture was absolutely required for exhibiting interconnected pores. The porous interconnected network leads to enable rapid tissue ingrowth and unimpaired diffusion of nutrients, oxygen and wastes. Through the natural derived cross-linking reagents with low toxicity, genipin³, CHI/HA scaffold could keep its stable form even up to 21 days in culture media.

Figure 1: SEM images of CHI/HA scaffolds prepared with (A) and without (B) β -GP.

Figure 2: Confocal image of WJ-SCs cultivated in CHI/HA scaffold (red staining). The cytoskeleton was visualized by actin filament staining with phalloidin (green labeling) with blue nucleus counterstaining of WJ-SC. Scale bare = 20 μ m.

LDH assay showed that scaffold has no cytotoxicity effect on WJ-SCs survival. Confocal imaging demonstrated CHI/HA scaffold colonization by WJ-SCs (Figure 2). Opposed to the plastic cell culture, WJ-SCs kept a round morphology when grown on the developed scaffold. A possible reason is that the 3D scaffold provides a geometrical distribution of binding sites to cells rather than planer conventional substrate⁴.

CONCLUSION

In this work a novel cell-colonized scaffold which exhibit highly porous and possess highly interconnected pores was developed. The original and simple thermogelling then freeze-drying approach ensure an easy transfer to the orthobiological industries. Nevertheless, understanding the mechanism and process of cell colonization in these 3D porous scaffolds are necessary for further physiological tissue models application.

Superficial Zn-Doping into Biomaterials is Better than Bulk Doping

Yuqin Qiao and Xuanyong Liu*

State Key Laboratory of High Performance Ceramics and Superfine Microstructure, Shanghai Institute of Ceramics, China qiaoyq@mail.sic.ac.cn and xyliu@mail.sic.ac.cn

INTRODUCTION

Rapid development of zinc biology has broadened the applications of Zn-incorporated biomaterials to tissue engineering but also raised concerns about the long-term safety of released Zn^{2+} ions¹⁻². Hence, clinical success hinges on the amount of incorporated zinc and subsequent optimized release that is sufficient to stimulate osseointegration. In this study, zinc is incorporated into the superficial surface of TiO_2 coatings by plasma immersion ion implantation and deposition (PIII&D). The Zn-implanted coatings show significant improvement compared to the “bulk-doped” coatings prepared by plasma electrolyte oxidation in terms of osteogenesis *in vitro*.

EXPERIMENTAL METHODS

Preparation of Zn-incorporated TiO_2 coatings

Plasma electrolytic oxidation (PEO) was conducted in Ca-P containing mixed electrolytes without/with zinc acetate to prepare Zn-free (Z0) and bulk-doped coatings (PEO-Z1 and PEO-Z2)³. In cathodic arc PIII&D, Zn was implanted into the Z0 coating to obtain Z0-PIII-Zn. All these coatings were characterized by SEM, EDS and XPS to determine Zn amount and distribution.

In vitro biological activities

Rat bone mesenchymal stem cells were used in passage 3 and seeded on Ti, Z0 and Zn-incorporated TiO_2 coatings to investigate effects of different zinc incorporation strategies on osteogenic activities: ALP activities and mRNA expression of osteogenic-related genes.

RESULTS AND DISCUSSION

The cross-sectional EDS maps (Ti, Ca and Zn) illustrated that Zn is present throughout the entire PEO-Zn coating but only exists superficially on Z0-PIII-Zn coating (Fig. 1). The Zn release profiles are direct reflections of the zinc contents between coatings with the following order: Z0-PIII-Zn < PEO-Z1 < PEO-Z2. Despite smaller Zn release at all defined time points, molecular and cellular osteogenic activities demonstrate that rBMSCs cultured on the Zn-implanted coatings display enhanced ALP activity and up-regulated osteogenic-related gene expressions (OCN, Col-I, ALP, Runx2, Fig. 2) compared to the bulk-doped Zn coatings (PEO-Z1 and PEO-Z2) and controls. The degree of accelerated osteogenesis appears to be in contrast to the released Zn concentrations and it somewhat conflicts former belief that a larger Zn concentration within the safety limits generally results in better osteogenesis in a given system. Our results show clear differences between these two types of Zn-incorporated coatings.

Fig. 1 Cross-sectional EDS mapping throughout the entire coating

Fig. 2 mRNA expression of osteogenic-related genes

CONCLUSION

Given the great clinical need, an understanding of the zinc regulation for bone formation is of critical importance in the design and fabrication of biomaterials for tissue engineering. In the present study, a systematic investigation is performed on two different modes of Zn introduction, namely, PEO and PIII&D, and detailed *in vitro* osteogenesis studies are conducted. The Zn-implanted coating (Z0-PIII-Zn), which possesses the smallest total zinc concentration, shows the best osteogenic characteristics.

Assessment of the biodegradability of ultrafine PCL fibers reinforced calcium phosphate cement

Yi Zuo^{1*}, Boyuan Yang¹, Fang Yang², Qin Zou¹, Jidong Li¹, Yubao Li¹ and J.A.Jansen²

^{1*}Research Center for nano Biomaterials, and Analytical & Testing Center, Sichuan Univ., China, zoe@scu.edu.cn

²Department of Biomaterials, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands

INTRODUCTION

Calcium phosphate cements (CPC) have gained clinical acceptance to repair the bone defect for their recognized bioactivity and moldability [1]. However, the inherent brittleness and slow resorption rate of CPC restrict its popular use [2]. In our previous study, electrospun fibers were added into CPC to fabricate a reinforced composite system [3], but the influence of the degradable fibers on CPC matrix degradation and tissue regeneration has not been addressed clearly. Herein, the effects of the incorporated ultrafine fibers on the composite CPC degradation and new bone formation were investigated by planimetric analysis as well as three-dimensional reconstruction method.

EXPERIMENTAL METHODS

Materials: The CPC cement powder (Biomet Merck, Germany) was mixed with 1wt% aqueous solution of Na_2HPO_4 . Ultrafine fibers ($\Phi 1.418 \pm 0.103 \mu\text{m}$) made of poly(ϵ -caprolactone) (PCL) (Mw 80,000, Sigma, USA) were prepared by electrospinning, then mixed with the CPC paste at fiber weight fractions of 0%, 3%, 7% to form the specimens (named UFRPC0, UFRPC3 and UFRPC7) with a dimension of $\Phi 5 \times 5 \text{ mm}$.

In vitro degradation: 5ml phosphate buffer solution (PBS) (pH=7.4) with 200 unit/ml lipoprotein lipase (Lipase-PS) was added in each vial. Electrospun fibers and UFRPC specimens were immersed in the lipase solution to study the enzymatic degradation for 1-7d at 37.8°C . The pH values of the residual solutions were measured at each time point. Then the specimens were fully washed and dried to a constant weight. A series of evaluations, such as mass loss, morphology observation, IR and XRD analyses, were carried out.

In vivo degradation: 36 New Zealand white rabbits were randomly divided into three experimental groups, and supracondyle defects ($\Phi 5 \text{ mm}$) were created in the femurs and filled with the UFRPC specimens. Macroscopic, histological and histomorphometric evaluations were performed at the time points of 4, 8 and 12 weeks post-operation. At 24 week, the remaining rabbits were sacrificed and the samples were harvested for micro-CT analysis.

RESULTS AND DISCUSSION

PCL has been used as a candidate polymer for long-term implantation due to its slow degradation ratio [4]. However, the ultrafine PCL fibrous structure could facilitate a faster degradation than its blocks; more than 50wt% fibers have been degraded in the enzyme solution on day 7. At the same time, the solution pH decreased with time until day 5 and then kept stable at a pH of 6.6. The mass loss data indicated that higher fiber content could accelerate the cement degradation. The SEM images showed that the ultrafine fibers on the cement surface degraded thoroughly after 3 days. The

IR and XRD analyses demonstrated a chemical transformation process that the α -tricalcium phosphate phase vanished by hydrolysis and formation of new hydroxyapatite crystals.

In vivo assessment suggested that the presence and degradation of ultrafine PCL fibers could promote the degradability of CPC matrix and new bone regeneration (Fig. 1). Comparing to pure CPC cement, the loaded ultrafine PCL fibers occupied more than 30vol% of the composite cement, and the degradation of fibers could afford abundant interconnective channels for CPC fast degradation and tissue regeneration. After 4 weeks, new bone has apparently grown into the UFRPC7 matrix. Afterwards, the cement matrix further degraded and the proportion of new bone reached 24% in volume at 24 weeks, higher than the ratio of others [5]. It can be seen from the blue colour of the 24-week longitudinal section (Fig.1b), the new bone tissue has formed an interconnective network structure in UFRPC7 composite cement, but the pure CPC cement maintained its dense structure without bone formation in its matrix.

Figure 1 Histological sections (a) and 3D micro-CT reconstruction (b) of the implanted cement samples.

CONCLUSION

Loading of electrospun PCL ultrafine fibers could afford CPC cement faster degradation and more new bone formation. It provides a prospective method to use degradable ultrafine fibers in preparation of bone cements or bone tissue engineering scaffolds.

Indian Institute of Technology (IIT) Madras, Chennai-600 036, Tamil Nadu, India

*Email Id: krishnamoorthyganesan@yahoo.com

INTRODUCTION

D-Amino acids (D-AAs) are non-genetically-coded amino acids (AAs) that either occur naturally or are chemically synthesized and becoming very important tools for modern drug discovery, chiral building block and also molecular scaffolds. D-AAs peptides are much more resistant to enzyme-catalyzed breakdown than L-residues. It is of profound interest to establish how the D-AAs exhibit better crosslinking of the collagen scaffolds in order to improve the thermomechanical properties and resistance to matrix metalloproteinase (MMPs) activities¹.

EXPERIMENTAL METHODS

This work was focused to design heterochiral collagen and improve the stability of collagen bioscaffolds by crosslinking them with D-AAAs and incorporation of phytosome nanoparticles (PNs) for their possible use in drug delivery and tissue engineering. In this study, D-AAAs assisted, 1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide (EDC)/N-hydroxyl succinimide (NHS) initiated crosslinking of collagen matrix (Coll-D-AAAs) were prepared and characterized and also incorporated PNs on collagen-D-AAAs scaffolds. The molecular level understanding of interaction of collagen like peptide (CLP) with selected D-AAAs was studied by molecular docking method. The inhibitory effects of selected plant extracts on collagenase activity against the degradation of collagen were studied. The PNs composed of phospholipids (PLs) with phytochemicals with varying molar ratios were prepared by heating under the N₂ atmosphere. The biocomposites Coll-D-Lys-PNs were prepared by thermally triggered Coll-D-Lys with preformed PNs.¹⁻⁵

RESULTS AND DISCUSSION

The results from thermomechanical analysis (TMA), differential scanning calorimetric (DSC) analyses and thermo gravimetric analysis (TGA) of the Coll-D-AAAs matrices indicate a significant increase in the tensile strength, % Elongation (% E), elastic modulus, denaturation temperature and a significantly decreased decomposition rate. Scanning electron microscopic (SEM) and atomic force microscopic (AFM) analyses revealed a well-ordered, properly oriented and aligned structure of the matrix. The improved properties of matrices can be further manipulated into the functional matrix suitable for the designing of scaffolds. The docking study has provided clear evidence for stabilization of collagen. The enzyme inhibition

kinetics has provided convincing evidences that MMPs are inhibited by plant extracts against the collagen degradation. ZP measurement confirmed the particle sizes and charges, and the SEM analysis confirmed the spherical surface morphology of PNs. These PNs loaded in the Coll-D-Lys biocomposites showed significant binding affinity to the cell and prolonged the release of model drugs and DNA from the scaffolds.

Fig. 1. SEM and AFM analyses and molecular modelling of Coll-D-Lys matrix.

CONCLUSIONS

These biocomposites could possibly be useful in bone and dental implants and in dura matter defects.

Supramolecular Anticancer Nanostructures Formed via Self-Assembly of Curcumin Amphiphiles

Koji Nagahama*, Naho Oyama and Takayuki Kumano

Department of Nanobiochemistry, Konan University, Japan, nagahama@center.konan-u.ac.jp

INTRODUCTION

Curcumin (CCM) inhibits the proliferation of a wide variety of human cancer cell lines including multidrug resistant cancer cells and cancer stem cells¹. Thus, CCM is an important alternative candidate as cancer chemotherapeutic agent. However, its application is limited because of low aqueous solubility (< 29.9 nM in water), quick hydrolysis in neutral and alkaline conditions (half-life < 10 min in PBS at pH 7.2), and low cellular uptake². To overcome the problems, we herein propose a supramolecular strategy to directly assemble CCM into chemically- and physically stable anticancer nanostructures with high and quantitative CCM loading, high cellular uptake, and high anticancer effect through π - π associative and hydrophobic interactions of CCM amphiphiles.

EXPERIMENTAL METHODS

CCM amphiphiles were synthesized by coupling reactions of hydroxyl group of CCM with hydroxyl groups of poly(ethylene glycol) (PEG) using CDI as coupling agent (Scheme 1). These amphiphiles were dissolved in pure water and stirred vigorously at room temperature to prepare their self-assembled nanostructures. The size and the distribution of the CCM nanostructures were analysed by DLS. The CCM nanostructures were visualized by TEM observations. The amounts of CCM released from the nanostructures were quantified by measuring UV-Vis absorbance of CCM ($\lambda = 430$ nm) in supernatant. Cytotoxicity of the CCM nanostructures against human cancer cell lines (PC-3, HL-60, HepG2) were examined by MTT assay.

RESULTS AND DISCUSSION

Three types of CCM amphiphiles, PEG-CCM (**PC**), PEG-CCM-PEG (**PCP**), and CCM-PEG-CCM (**CPC**), with different hydrophilic/hydrophobic balance were synthesized and used following experiments. Purity of these amphiphiles was confirmed to be over 99% using gel permeation chromatography. TEM imaging reveals that all the CCM amphiphiles assembled into spherical nanostructures in water (Figure 1a and b). While **PC** and **PCP** formed micellar structures, **CPC** formed vesicular structures. Their ¹H-NMR spectra in D₂O reveals that CCM located interior of the nanostructures to form stable core and PEG chains located at the surfaces with well-extended structures to form water-soluble shell, suggesting that these nanostructures were formed through combination of π - π associative and hydrophobic interactions between CCM molecules. Diameters of the nanostructures were 228 ± 31 nm (**PC**), 180 ± 24 nm (**PCP**), and 155 ± 21 nm (**CPC**), respectively. Based on the geometry, these nanostructures were well-dispersed in water even at high concentrations. The maximum water solubility of CCM nanostructures were 15.6 mM (**PC**), 10.3 mM (**PCP**), and 14.1 mM (**CPC**), respectively. Although

Scheme 1. Synthesis of PEG-CCM conjugates (**PC**).

half-lives of CCM amphiphiles in water was shorter than 6 h at below their critical assembly concentrations which CCM amphiphiles can't form nanostructure, CCM nanostructures exhibited significant longer half-lives (**PC**: 42 h, **PCP**: > 168 h, **CPC**: 72 h). These results indicate that the supramolecular strategy is effective to improve water solubility and resistance to hydrolysis of CCM. The CCM contents (loading contents) of nanostructures were precisely controlled to be 32% (**PC**), 19% (**PCP**), 32% (**CPC**), respectively.

Figure 1. TEM images of **PC** (a) and **PCP** (b). Scale bar indicates 200 nm. (c) Anticancer effect of **PCP** against HL-60 cells. Inserted fluorescence microscopic image indicates HL-60 cells treated with **PCP** for 1 h.

CCM were gradually released from the nanostructures without initial burst and approximately 20% of loaded CCM were released after 14 days in cell culture medium at 37 °C. Almost 100% of CCM nanostructures entered both adhered (PC-3 and HepG2) and dispersed (HL-60) cancer cells after 2 h of incubation and mainly accumulated in the cytoplasm (Figure 1c). The CCM nanostructures inhibited cancer cell proliferation with 2-4 times lower IC₅₀ values than that of free CCM. Moreover, it was demonstrated that treatments of the CCM nanostructures induce apoptosis to cancer cells.

CONCLUSION

We have reported a novel strategy to construct CCM-based anticancer nanostructures with a high and fixed CCM content. We thought this strategy can be extended to fabricate nanostructures of other important anticancer drugs. Moreover, this strategy opens up new opportunity to develop "drug self-delivery systems".

Silica/Collagen Nanocomposites for Local and Sustained Release of Therapeutic Biomolecules

Xiaolin Wang, Christophe Hélarly and Thibaud Coradin

Sorbonne Universités, UPMC Univ Paris 06 and CNRS, UMR 7574, Chimie de la Matière Condensée de Paris, France, wxlpharma@hotmail.com

INTRODUCTION

Local delivery of DNA and siRNA using a hydrogel scaffold extends the application of gene therapy for the treatment of tissue diseases such as chronic skin wounds. However, the inactivation and fast release of encapsulated DNA and siRNA strongly circumvent their efficacy¹. In this study, we propose to use nanocomposites consisting of polyethyleneimine (PEI)-DNA complexes associated with silica nanoparticles (SiNP) to modulate PEI toxicity², collagen hydrogel and 3T3 fibroblasts to build a local “cell factory” to achieve a sustained and programmed release of biomolecules.

EXPERIMENTAL METHODS

200 nm SiNP were prepared through the Stöber process and then subjected to surface modification with PEI of different molecular weights (1.8 kDa, 10 kDa and 25 kDa) in PBS pH 7.4. The SiNP-PEI particles were complexed with pCMV-GLuc plasmid and encapsulated³ within 1 mg.mL⁻¹ collagen hydrogels with 10⁵ cells.mL⁻¹ 3T3 mouse fibroblasts. The resulting 3D nanocomposites (Figure 1) were cultured over one week and samples collected at day 2, 5 and 7. Internalization of the SiNP-PEI in 3D system was checked by fluorescence microscopy. Cell transfection was assessed by measuring the luciferase activity (RLU) in the culture medium; cell viability was evaluated by the Alamar BlueTM Assay. PEI-DNA complexes were used as positive control.

Figure 1: Scheme of prepared nanocomposites

RESULTS AND DISCUSSION

Monodispersed SiNPs were obtained (Figure 2A) and internalization of SiNP-PEI-DNA into 3T3 fibroblasts was confirmed by fluorescence microscopy (Figure 2B). Successful cell transfection was detected by sustained release of luciferase over one week (Figure 2C). For the PEI-DNA complexes, an increase of cell transfection efficiency was observed with the increase of molecular weight. Regarding the SiNP-PEI-DNA complexes, 10kDa PEI allowed the highest expression of luciferase. This expression increased during the course of the experiment and was higher than that obtained with the 10 kDa PEI-DNA complexes. Interestingly, 1.8kDa PEI alone doesn't show any transfection capability while expression of luciferase was detectable when combined with SiNP. The enhancement of cell transfection for PEI 10 kD and 1.8 kD by SiNP suggests that SiNP offsets the positive charge of PEI while facilitating cell internalization of DNA complexes. The good cell viability through all group of DNA complexes

could be attributed to fast proliferation of the given cell line.

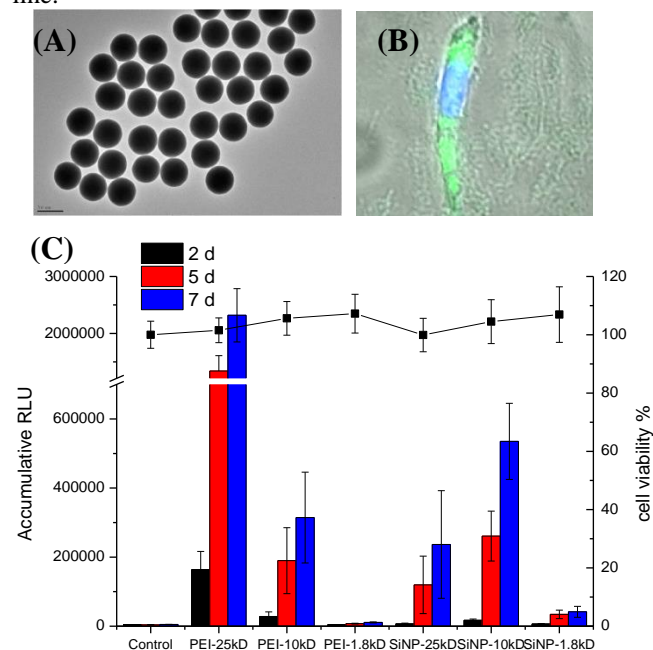

Figure 2: Transfection of 3T3 fibroblast by SiNP-PEI-DNA complexes in 3D. (A) TEM image of SiNP ($\times 11,000$). (B) Merged fluorescence microscopy image showing internalization of SiNP-PEI-DNA complexes within 3D system; complexes were labeled with FITC (green) and cell nucleus was labeled by DAPI (blue) ($\times 400$). (C) Accumulative RLU at 2d, 5d, 7d (histograms, $n=6$); cell viability was calculated in the percentage of control (dotted line, $n=6$).

CONCLUSION

These results show that nanocomposites obtained by entrapping SiNP-PEI-DNA together with cells inside collagen hydrogels can act as a reservoir for local and controlled gene delivery. By selection of PEI size, it is possible to lower toxicity while maintaining high transfection efficiency. Therefore, the as-constructed 3D system has promising applications for the controlled expression and release of therapeutic biomolecules for tissue engineering.

INTRODUCTION

Bone Morphogenetic Proteins (BMPs) play an essential role in several developmental processes, especially in bone formation and regeneration. In the field of orthopedics and maxillo-facial surgery, localized delivery of BMPs from the surface of implantable materials may improve bone formation around the implant. Using the layer-by-layer technique, we have developed a biomimetic film made of biopolymers, which acts as a nanoreservoir to trap BMP-2 and to present it to cells in a "matrix-bound" manner^{1,2}. This presentation mode more closely mimics the natural environment *in vivo*. *In vitro* bioactivity of trapped BMP-2 was confirmed using alkaline phosphatase assay and SMAD signaling². *In vivo* osteoinductive potential was proved for films deposited on titanium scaffolds in a rat ectopic assay³.

Here, our aim was to analyse the implant/film interface and to understand how cells are sensing the BMP-2 presented in a "matrix-bound" manner by the film.

EXPERIMENTAL METHODS

Poly(L-Lysine/Hyaluronan (PLL/HA) films were built by the layer-by-layer technique using an automated dipping machine (DR3, Kierstein and Viegler) and subsequently cross-linked using carbodiimide chemistry. The loaded BMP-2 amount and its release over time were quantified using fluorescently labeled BMP-2 by means of a fluorescence spectrometer (TECAN Infinite 1000). The vertical diffusion of the fluorescein labeled BMP-2 inside the film (labeled with PLL-Alexa568) was studied using a confocal microscope (Zeiss LSM 700). Protein secondary structure in solution and in the films was assessed using FTIR spectroscopy (Bruker Vertex 70).

Uptake of BMP-2 by the cells was also studied by confocal microscopy. Several inhibitors of endocytosis were used to investigate the internalization route for BMP-2 as well as their effect on the BMP-2 signalling pathways. Knock-down of receptors using siRNA was applied to study the role of BMP receptors in the internalization process.

RESULTS AND DISCUSSION

The protein secondary structure was obtained by FTIR spectroscopy. Figure 1A shows the Amide I band spectrum of BMP-2 in solution (1 mM HCl, i.e. pH 3) and Figure 1B when loaded in a (PLL/HA) film. After isolating the protein spectrum from that of the film and decomposing the different bands, a very similar structure was observed for BMP-2 in solution or trapped inside the film matrix⁴. The structure of the film allowed BMP-2 to conserve its characteristic secondary structure: a large fraction of intramolecular β -sheets

(~ 50%) and to maintain its central α -helix⁴. The biopolymeric film plays the role of a stabilizer, or protective carrier for the protein⁴.

Figure 1: Secondary structure of BMP-2 (A) in solution and (B) inside a hydrated (PLL/HA) film. Structural elements: intramolecular β -sheets (orange), unordered structures (green), α -helix (blue), β -turns (purple) and intermolecular β -sheets (gray).

Furthermore, we evidenced that C2C12 cells internalize the fluorescently labeled BMP-2 as can be observed by the presence of green dots inside the cells, which are internalization vesicles (Figure 2). Several parameters related to endocytosis of BMP-2 were subsequently studied.

Figure 2: 3D reconstruction using confocal microscopy of a C2C12 myoblast on top of a biopolymeric film (red) loaded with BMP-2 (green) after internalization.

CONCLUSION

Understanding how cells can respond to bioactive proteins presented by a biomaterial is of importance for future clinical applications of this biomaterial. Here, we evidenced that matrix-bound BMP-2 can be internalized, which is related to BMP-2 signalling. The important role of BMP receptors in this process has also been shown.

INTRODUCTION

Nanobiotechnology, the integration of nanotechnology with molecular biology and medicine, is an emerging research area that has experienced rapid growth over the past decade because it offers exciting opportunities for discovering new science, producing novel materials, and developing efficient processes.

Recently, the use of magnetic nanoparticles (MNPs) for biological and medical purposes has been increasing due to their unique reaction to applied magnetic forces (e.g., hyperthermia applications, as a contrast agent for magnetic resonance imaging and magnetic drug delivery). Recent interest has focused in their use for tissue engineering^{1,2}. Here novel biocompatible and bioresorbable superparamagnetic nanoparticles (NPs) fabricated by doping hydroxyapatite (HA) with Fe ions (FeHA), avoiding any coating and the presence of poorly tolerated magnetic secondary phases, were investigated in vitro. This study aimed to investigate the cellular response to FeHA NPs and to clarify the mechanism by which mouse mesenchymal stem cells internalized the FeHA NPs, in order to lay the basis for future approaches for biology and medicine applications.

EXPERIMENTAL METHODS

Magnetic biomimetic Fe-HA powder was prepared by a neutralization process using FeCl₂ and FeCl₃ as a source of Fe²⁺ and Fe³⁺ doping ions³.

HA nanopowder already employed in orthopaedic clinic applications was used as control. Mesenchymal stem cells were plated at a density of 1×10^4 cells/cm² and were incubated with two different concentrations of FeHA NPs: 200 µg/ml and 100 µg/ml for different time points.

Cell proliferation, cell viability and osteogenic differentiation were investigated (qPCR). Moreover, the cellular uptake was quantified by ICP-OES measure of iron [Fe] concentration in the cellular lysates. Immunofluorescence analyses and morphological analysis by transmission electron microscopy were assessed.

RESULTS AND DISCUSSION

Assays for cell proliferation, viability and morphology did not show any differences among FeHA NPs and HA NPs groups with different concentration at each time points. This indicated that the novel superparamagnetic FeHA NPs did not cause any cytotoxicity and were comparable to the HA NPs.

A very high ratio of live cells compared to the very few dead cells were seen in every FeHA NP group in quantities comparable to HA groups. Moreover these particles strongly enhanced MSCs osteogenic differentiation as demonstrated by gene expression analysis.

Cellular uptake shown that mesenchymal stem cells were able to quickly internalize the NPs and they became “magnetic cells”. In fact we were able to move and to align the cells when an external magnetic field was applied.

CONCLUSION

This study showed the great potential that novel MNPs may offer in biology and medicine applications.

The preliminary data obtained on the cellular uptake of FeHA NPs lay the basis to clarify the fate of the intracellular particles and open future prospective on the possibility to magnetize the cells with FeHA NPs. “Magnetized” cells could be injected and directed to a desired bone site to increase cell proliferation and enhance bone formation using an external magnetic field. Moreover FeHA NPs could be functionalized with several growth factors and/or drugs induce tissue regeneration and reducing the recovery time.

INTRODUCTION

Reactive oxygen species (ROS) are closely linked with initiation and progression of cancer, arthritis and other inflammatory diseases.^[1] In addition, they are angiogenic mediators and promote angiogenesis which is essential for tumor growth and metastasis.^[2]

In the field of drug delivery, polymeric nanoparticles, generally in the range of 10-100 nm in dimension, are often used to deliver a wide variety of drugs including anti-cancer drugs and nucleic acids. They have been shown to prolong circulation time, improve biodistribution and minimize side effects of drugs.

The objective of this study is to develop antioxidant micelles which inhibit angiogenesis by scavenging ROS in tumor tissues. Here we report polymeric micelles bearing catechol moieties with antioxidative activity that have an inhibitory effect on angiogenesis.

EXPERIMENTAL METHODS

Poly(ethylene glycol)-poly(dopamine) (PEG-PDA) diblock copolymers (Figure 1A) were synthesized by reversible addition-fragmentation chain transfer (RAFT) polymerization. The antioxidant micelles were prepared by dispersing PEG-PDA diblock copolymers in acetate buffer (pH5.0). The micelles were characterized by dynamic light scattering (DLS) and transmission electron microscopy (TEM). To evaluate the oxidation stability of the catechol moieties under aerobic condition, dopamine (DA) and PEG-PDA micelles were kept in air-saturated phosphate buffered saline (pH7.4) at 37°C and tested for H₂O₂ scavenging activity using Amplex Red assay. To investigate whether DA and PEG-PDA micelles are able to exert an anti-angiogenic effect by scavenging endogenous ROS, we evaluated their effects on the tube formation of human umbilical vein endothelial cells (HUVECs) *in vitro*. Furthermore, the anti-angiogenic activity of PEG-PDA micelles was evaluated in the *ex ovo* chicken chorioallantoic membrane (CAM) assay.

RESULTS AND DISCUSSION

DLS showed that the PEG-PDA block copolymers formed micelles (50 nm in diameter) with narrow size distribution. The TEM image showed the spherical shape of the micelles.

Freshly prepared solutions of DA and PEG-PDA micelles scavenged 80-90% of the added H₂O₂. In the case of DA, the H₂O₂ scavenging activity was reduced under aerobic condition as function of incubation time. After 48 h, the amount of the scavenged H₂O₂ decreased to 50%. In addition, we observed a dark-brown precipitate. Contrary to DA, PEG-PDA micelles had similar H₂O₂ scavenging activity without formation of precipitate after 48 h.

Figure 1. A) Chemical structure of PEG-PDA diblock copolymer. Fluorescence images of ROS in HUVECs treated with B) water (control), C) DA and D) PEG-PDA micelles.

The tube formation capacity in HUVECs was impaired upon the addition of PEG-PDA micelles while the treatment with DA did not show obvious effects. To confirm that the inhibitory effect was due to the ROS scavenging activity of the micelles, the intracellular ROS level in HUVECs treated with DA and PEG-PDA micelles was visualized using the ROS-detection dye, dichlorofluorescein-diacetate (Figure 1B-D). In the case of PEG-PDA micelles, the fluorescence due to the intracellular ROS was not observed while DA slightly diminished the intracellular ROS level. These results indicate that the long-lasting ROS-scavenging activity is critical to exert an anti-angiogenic effect.

We further evaluated the anti-angiogenic activity of the PEG-PDA micelles in the *ex ovo* chicken chorioallantoic membrane (CAM) assay. The micelles efficiently inhibited capillary formation on the CAM, while DA treatment showed only a weak inhibitory effect.

CONCLUSION

The PEG-PDA micelles showed high oxidation stability under aerobic condition. In the tube formation assay and the CAM assay, the micelles exerted anti-angiogenic activity. These results suggest that the antioxidant micelles may be useful in anti-angiogenic therapy to treat many diseases including cancer.

Design of Biodegradable pH-Responsive Microgels as Targeted Drug Delivery System

Miren K. Aiertza, Pablo Casuso, Adrián Pérez-San Vicente, Hans-Jurgen Grande, Germán Cabañero, Iraidia Loinaz and Damien Dupin

Biomaterials Unit, Materials Division, IK4-CIDETEC, Spain, maiertza@cidetec.es

INTRODUCTION

Efficient drug delivery is one of the most important challenges in cancer treatment¹. Considerable efforts focus on the preparation of targeted vehicle to transport drugs to tumour cells.² Such delivery system requires i) good encapsulation properties, ii) efficient drug targeting/release, iii) biocompatibility and, iv) facile elimination from the body.³

Stimuli-responsive microgels, which are submicrometer-sized particles that can be swollen by change of pH, have gained growing attractions as drug delivery systems. Herein, we report the design of folic acid-functionalised microgels that can transport hydrophobic compounds to the tumour cells and release their cargo during endocytosis at lysosomal pH.

EXPERIMENTAL METHODS

Microgel synthesis via aqueous emulsion polymerization. 2,2'-(diisopropylamino)ethyl methacrylate [DPA] was polymerized in water in the presence of *N*-(3-aminopropyl)-2-methylacrylamide hydrochloride (APMA) comonomer, 2-methylene-1,3,6-trioxocane (MTC), ethylene glycol diacrylate (EGDA) cross-linker, poly(ethylene glycol) ethyl ether methacrylate stabilizer (PEGMA) and ammonium persulfate (APS) initiator via aqueous emulsion polymerization at 70 °C to obtain PEGMA-PDPA particles. PDPA particles were decorated with folic acid.

Dynamic Light Scattering (DLS) and Zeta potential studies were carried out using Malvern Zetasizer Nano ZS on particles dispersion at 0.01 wt. % in PBS.

PDPA particles cytotoxicity was investigated via MTS and Live/Dead assays in the presence of HeLa cells.

RESULTS AND DISCUSSION

Lightly cross-linked PEGMA-PDPA particles of around 200 nm were obtained via aqueous emulsion polymerization.

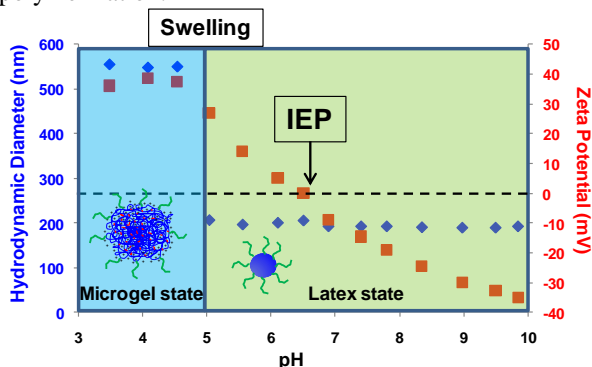

Figure 1. DLS (♦) and Zeta potential (■) of PEGMA-PDPA particles in function of the solution pH in PBS solution.

As judged by DLS, PEGMA-PDPA particles exhibited a latex-to-microgel transition at pH 6.5 due to the protonation of the tertiary amine of the DPA residues (**Figure 1**). This indicates that PEGMA-PDPA will swell up with water to 550 nm during the endocytosis process as originally targeted. It is worth mentioning that the presence of the PEGMA stabilizer is absolutely required to ensure colloidal stability in physiological conditions with high concentration of salt. Moreover, the copolymerization of MTC comonomer offered hydrolysable bonds into the particles facilitating its degradation. PEGMA-PDPA particles were efficiently degraded after 1 week in the presence of lipase at physiological conditions into shorter polymer chains easily eliminated by the kidney.

PEGMA-PDPA particles did not exhibit cytotoxicity in the presence of HeLa cells (**Figure 2**). Moreover, hydrophobic dye could be encapsulated into the particles. The presence of folic acid at the particle surface increased cellular uptake and the dye was released efficiently as judged by fluorescence microscopy.

Figure 2. Viability (left) and Live/Dead assays (right) of HeLa cells in the presence of PEGMA-PDPA particles (50 µg L⁻¹) after 3 days (scale bar: 100 µm).

CONCLUSION

The judicious choice of stabilizer and comonomers allowed the preparation of stable, biodegradable and biocompatible pH-responsive microgels easily functionalised with targeting molecules. Hydrophobic compounds could be encapsulated at physiological conditions and efficiently released during endocytosis due to the swelling of the particles occurring at lysosomal pH.

A Biotemplating Approach Using the Marine Diatom for Fabricating Drug Delivery Reservoirs

J. Chao¹, Y. Lang¹, A. Abdul-Rahman¹, M. Biggs¹, A. Pandit¹

¹Network of Excellence for Functional Biomaterials (NFB), National University of Ireland, Galway, Ireland
J.CHAOI@nuigalway.ie

INTRODUCTION

In the field of biomedical engineering, the use of natural systems as templates – termed “biotemplating” – has been argued to provide many biomimetic advantages over conventional biomaterials and drug delivery platforms¹. Diatoms are unicellular, eukaryotic algae surrounded by an outer “frustule” wall, which is highly differentiated and impregnated with amorphous silica². The hierarchical structure of the diatom is species-specific and composed of highly ordered pores, giving a large surface area for biomolecule conjugation; however, due to the cytotoxicity of the biogenic silica, there is a need to fabricate a polymeric replica of the diatom for drug delivery purposes. The authors have previously shown success in grafting a pDMAEMA-co-EGDMA polymer onto the diatom³ and, in this abstract, we present our findings on utilizing layer-by-layer (LbL) assembly of poly-L-lysine (PLL) and hyaluronic acid (HA) to form biodegradable polymeric bilayers on the marine diatom *Thalassiosira weissflogii*.

EXPERIMENTAL METHODS

Culturing of *Thalassiosira weissflogii*. Axenic cultures of *T. weissflogii* were grown in artificial seawater and enriched with Guillard’s f/2 marine enrichment media without silicates. Cultures were grown in polystyrene tissue culture flasks, with 14:10-hour light:dark cycle, 3000 lux light intensity, and temperature range of 16–22°C. Cultures were inoculated at a density of 1×10^4 cells/mL in 200 mL of ASW, and sodium metasilicate was added to flasks at a final concentration of 200 μ M.

Preparation & characterization of cleaned frustules. Cultures were collected 192 h post-inoculation and organic matter was removed by successive washes of H₂O (3x), 1:1 HCl:H₂O (3x), H₂O (3x), and methanol (6x), each rinse followed by centrifugation at 2500 rpm for 20 m. Cultures were treated with chitinase for 72 h to remove chitin extruded from the diatom.

Layer-by-layer assembly of polyelectrolytes. PLL and HA solutions were prepared in 0.05M MES buffer (pH 5.5) at 1 mg/mL. Polyelectrolytes were incubated with diatoms at 25°C for 15 m, and layers were confirmed using quartz crystal microbalance and zetasizer.

RESULTS AND DISCUSSION

Morphological and topographical characterization revealed a highly porous architecture (Fig. 1). Scanning electron microscopy was used to visualize the intricate hierarchical template, confirming clean and chitin-free diatom skeletons. Transmission electron microscopy revealed the porous architecture of the frustule with pore sizes measuring 40.4 ± 2.09 nm. Quartz crystal microbalance with dissipation monitoring (QCM-D) was used to quantify the layer thickness and mass deposited, and zetasizer indicated surface charge of the frustule to oscillate between 34.4 ± 1.90 mV and -22.6 ± 1.11 mV for PLL and HA layers respectively (Fig. 2).

Figure 1. **Topography of *T. weissflogii*.** (A) Diatoms are abundant and amenable to scale-up. (B) Arrow highlights girdle bands alongside frustule. (C) External view of valve face with arrows highlighting fulcra. (D) Zoomed-in view of fulcra. (E) TEM shows porous architecture with rib-like structure. (F) AFM shows morphology of diatom valve face (scale = 200 nm, x-/y-axis div: 1 μ m, z-axis div: 200 nm).

Figure 2. **Analytical methods confirm polyelectrolyte deposition.** (A) QCM-D shows polyelectrolyte binding. (B) Zeta potential of oppositely charged polyelectrolytes indicates binding of successive layers on diatom.

CONCLUSION

The authors have visualized and quantified the morphology of the diatom, as well as shown novel binding of PLL and HA bilayers onto a diatom template. Dissolution of biogenic silica will produce a free-standing biodegradable diatom replica. Model water-insoluble drugs with pDNA will be incorporated within the bilayers and release kinetics will be further investigated.

Effect of mesoscale structure on the properties of composite scaffold: from micro to nano

Limei Li, Yi Zuo, Jidong Li, and Yubao Li*

*Research Center for Nano Biomaterials, and Analytical & Testing Center, Sichuan Univ., China, nic7504@scu.edu.cn

INTRODUCTION

Apatite/polymer composites have been developed to mimic the natural extracellular matrix of bone^[1]. The incorporation of apatite nanoparticles can significantly affect the properties of the polymeric matrix^[2]. And the nanoparticles tend to aggregate because of high surface energy^[3]. Moreover, mesoscale structure between the microscale and nanoscale, which formed a structure domain by the regular aggregation of organic molecules or inorganic crystals, has not been noticed for this class of composite. A more detailed understanding of the mesoscale domain formation in composite is associated with more stable and homogenous matrix for scaffold fabrication. This study tried to explore how the micro to nano mesoscale structure influences the properties of the composite scaffold.

EXPERIMENTAL METHODS

Polyurethane was chosen as the model polymer for its specific micro-structure formed by hard and soft chain segments. Here, castor oil (CO) and glycerin-esterified castor oil (GCO) copolymerized respectively in a three-necked flask with isophorone diisocyanate (IPDI) with addition of 40 wt% micro- or nano- hydroxyapatite (HA) particles. The weight ratio of IPDI to CO or GCO was 1:1 in all cases and the reaction was kept for a period of 3 h in an oil bath at 70 °C. Then HA/PU slurry was cured and foamed at 110 °C. Finally, we obtained four groups of porous scaffolds, i.e. n-HA/PU, n-HA/GPU, μ -HA/PU and μ -HA/GPU, in which PU was from CO, and GPU was from GCO.

Cryogenic ultramicrotome was used to prepare ultrathin samples and autheniumtetraoxide (RuO₄) was used as staining agent for TEM observation. NMR, XPS and FTIR were used to analyse the chemical composition and bonding. Thermal ability and dynamical mechanics performance were tested by DSC and DMA, respectively.

RESULTS AND DISCUSSION

Fig. 1 and Fig. 2 shows the TEM images of the four composites, in which the n-HA crystals are uniformly distributed in PU (1c, 1e) or GPU (1d, 1f) matrix with close interface integration (2c, 2d). However, there are clear interface gaps between the μ -HA particles and PU or GPU matrix, although the interface of μ -HA/GPU (1b) looks better than μ -HA/PU (1a). On the one hand, the GCO with more -OH groups can fully react with IPDI to increase the polymerization; on the other hand, the abundant functional groups of GCO will bond with the dangling P-O or -OH bonds of n-HA crystals to realize the close interface structure.

The peaks of NMR and XPS spectra in Fig. 3 (A-C) indicate that the chemical process enables n-HA crystals closely combine with PU or GPU matrix. It can be noted that the molar concentration of the peak at about 400.0 eV (CO-N-CO) increases in an order of μ -HA/PU,

μ -HA/GPU, n-HA/PU and n-HA/GPU, driven by the less reaction inhibition in n-HA/GPU (19.93%). The data coincide with the best miscibility of n-HA/GPU composite, characterized by either the close interface or the bonding domain of hard and soft segments (Fig. 2).

Fig. 1 TEM images and SAED patterns of composites

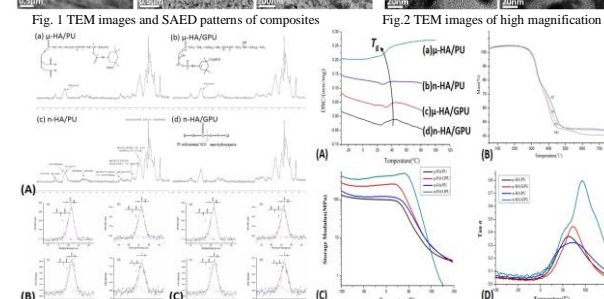

Fig.2 TEM images of high magnification

Fig. 3 (A) ¹³C NMR spectra, (B) C1s XPS spectra and (C) N1s XPS spectra of composites

Both the nanoscale of n-HA crystals and the esterified GCO, present a significant influence on the properties of the HA/PU composites. In the curves of DSC and DMA in Fig. 4, the value of T_g increases from 35 °C to 45 °C and storage modulus of composites increase largely with the hydroxyl value, from 159 mg KOH/g (CO) to 288 mg KOH/g (GCO). The homogenous nanoscale structure truly enhances the macro performance of the composites. The compressive strength is 2.23, 2.40, 2.44 and 4.27 for μ -HA/PU, μ -HA/GPU, n-HA/PU and n-HA/GPU, respectively.

CONCLUSION

This study testified that the mesoscale structures would affect the macro performance of HA/PU composites significantly and synergistically, not only by the nano size of the inorganic HA crystals but also by the bonding domain of soft and hard segments of polyurethane.

y.ryabenkova@sheffield.ac.uk

INTRODUCTION

Biomaterials composed of hydroxyapatite (HA) are currently clinically employed for the treatment of bone defects resulting from trauma or surgery¹. Nanoscale hydroxyapatite supplied in the form of a paste is considered very attractive compared to calcium phosphate cements where powders and liquids need to be mixed immediately prior to surgery. In this study, we have tested nanoscale hydroxyapatite (nHA) pastes prepared using two types of nanoparticle with different morphologies (with particle-water load, macro-porosity and level of agglomeration being constant), and evaluated their properties at different temperatures. The aim of this research was to understand the structure-property relationships that underpin clinical success including handling.

EXPERIMENTAL METHODS

The nHA pastes were supplied by the IMCOSS project partners and characterized using X-ray diffraction (XRD) for phase analysis, and attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FTIR) for the determination of functional groups. Morphology studies were carried out using high resolution transmission electron microscopy (HR-TEM), whereas the rheological behaviour has been evaluated using a modular compact rheometer (MCR) in both rotational and oscillating modes.

RESULTS AND DISCUSSION

The HA particles of two types appeared to be rod shaped with the size ranging from 20 nm to 80 nm and differing from one another by aspect ratio and the level of roundness/sharpness (Fig. 1). They were shown to be made of a phase pure HA with low crystallinity, containing small inclusions of carbonates most likely due to the relatively high pH used during their preparation.

The rheological properties were investigated by performing steady and dynamic tests, and revealed that the nHA pastes were thixotropic shear-thinning non-Newtonian fluids. Differences in viscosity and yield stress were detected between the two pastes, with one of them having the highest viscosity and being harder to handle, thus suggesting poorer injectability properties. This was assumed to correlate with the morphology of the constituent particles. Interestingly, temperature modified the rheological behaviour, suggesting better

injectability may be obtained at lower temperatures (ca. 10°C).

In addition, the two materials with expected low and high viscosities were mixed at the stage of slurries forming the pastes, with the aim of producing homogeneity of mixing. Rheology tests of the resulting paste showed that the viscosity does not change linearly when mixing the two materials with different characteristics, thus giving the opportunity to prepare mixtures with the desired viscosity values.

Figure 1. TEM micrographs of: (left) HA nanoparticles with higher aspect ratio, (right) HA nanoparticles with lower aspect ratio (scale 40 nm). The viscosity of the pastes changes drastically being significantly lower for the higher aspect ratio HA particles (on the left) thus leading to easier handling.

CONCLUSION

Injectability is a complex phenomenon with many determining factors. It was concluded that it was possible to influence injectability of the nHA pastes by combining particles with different morphologies. Temperature also appeared to be a critical factor that must be taken into account when handling these non-Newtonian bone graft materials, as it modified viscosity and therefore influenced the injectability.

INTRODUCTION

Biodegradable polyurethane elastomeric scaffolds have great interest in soft tissue repair and regeneration. But the proper design of these materials employed for tissue engineering application is still challenging because of the lack of tissue-material compatibility that are susceptible to provoke foreign body response and unwanted inflammatory reactions.

The presence of zwitterionic polynorbornene in the soft segment as chain extender with attached crosslinker in the polyurethane elastomer could provide with robust mechanical properties and faster degradation behavior. The present work is also continuations which address several important issues faced as well the approach employed thiol-ene click reaction, required mild experimental conditions, show high yields, require small concentrations of benign catalysts, have rapid reaction rates, require essentially no cleanup, and are insensitive to ambient oxygen and water. Moreover, the final materials exhibited some of the novel characteristics, such as mechanical, biodegradable and biocompatible properties, which have great demand for the current synthetic TE materials applications.

EXPERIMENTAL METHODS

The zwitterionic polymer, poly(NSulfoZI) was synthesized according to our previous method using the same designed principle of ring opening metathesis polymerization (ROMP).¹ Polyurethane (PCU) and zwitterionic polynorbornene based elastomeric crosslinked film as cell growth substrate was prepared using thiolene click-chemistry and crosslinking reaction.

They were characterized by FT-IR, water contact angle and mechanical test. Cytotoxicity, growth and proliferation of endothelial cells EA.hy926 were evaluated *in vitro*.

RESULTS AND DISCUSSION

The various cross-linked PCU films with different ratios (wt%) of zwitterion polynorbornene poly(NSulfoZI), acting as chain extender were prepared by a two steps method using a combination of click chemistry and crosslinking reaction (curing) at different temperature and time schedule. Firstly amine functionality was introduced into polynorbornene (poly(NSulfoZI) having functionalizable double bonds by treating with L-cysteine using photoinitiated thiolene click-reaction,

followed by controlled reaction with PCU-solution in the presence of diisocyanate cross-linker. The obtained films possessed improved tensile strength of (14-20 MPa) and initial modulus (8-14 MPa), in comparison to 12 ± 4 MPa and 3 ± 1 MPa respectively, for blank film. All of these films including blank one, showed high breaking strain (eb 740-900%), except with a highest zwitterion content of 28% (eb $470 \pm 80\%$). The biodegradability of these materials was enhanced, tested in PBS for 5 weeks as against blank PCU. The blank PCU-film surface could also be modified under the aforementioned condition using L-cysteine or β -marcaptoethanol as thiol-agents.

The cytocompatibility of all these materials investigated by MTT assay indicated that the designed materials were non-toxic and showed good cytocompatibility towards ECs, EA.hy926.

The adhesion and proliferation of EA.hy926 endothelial cells (ECs) on different films surfaces were morphologically evaluated by SEM for 1, 3 and 7 days. The modified films provided a good environment for the ECs growth. The blank PCU surface scarcely adhered ECs, and the adhered cells showed poor growth even after 3 and 7 days. So these finding indicated that these materials significantly improved support towards the growth of ECs when employed as growth substrate.

CONCLUSION

The elastomeric polycarbonate urethane and zwitterion crosslinked films were prepared through the convenient method using click chemistry and crosslinking reaction. These obtained films combined unique characteristics of both the parent materials such as improved biodegradability, reasonable mechanical and excellent biocompatible properties. Moreover, these designed materials showed enhanced growth and proliferation of endothelial cells.

INTRODUCTION

The interaction between the surface of an implant and the surrounding tissue is a crucial factor for its efficiency in the human body. If the surface is bioinert or bioincompatible, this property can be changed by establishing bioactive coatings. Our group has already successfully introduced mesoporous silica films as a novel type of coating which allows modification of and local drug delivery from implants¹⁻³. Periodic mesoporous organosilica (PMO) coatings⁴ could also offer a variety of useful characteristics for biomedical applications and are more versatile due to their hybrid construction. In PMOs, the siloxane bridges of silica are substituted by organic linkers. Correspondingly, the chemical, physical and mechanical properties of the PMO coatings can be adjusted by the chemistry of the organic bridging groups in the precursors. PMO films could be mechanically more flexible than pure silica films which is of interest for the coating of flexible implants. The pores of PMOs can exhibit more strongly hydrophobic properties which could be used for the delivery of unpolar, water-insoluble drugs. First studies with simple drug delivery processes from PMOs⁵ show promising results with regard to biomedical applications.

Here, we present comprehensive investigations on the properties of PMO coatings as a novel biomaterial. Apart from basic characterization, the focus is on mechanical properties, on biocompatibility studies as well as on the loading and release of the drug ciprofloxacin (CFX). The organic-inorganic silica precursor used for the synthesis of the PMO coatings is 1,4-bis(triethoxysilyl)benzene (BTEB). Here, the siloxane bridges of silica are substituted by phenylene units.

EXPERIMENTAL METHODS

PMOs coatings were generated on plain glass slides by sol-gel dip-coating. To obtain the coating solutions, the PMO precursor (here BTEB), structure-directing agents (SDAs, here Pluronic F127), ethanol, water and hydrochloric acid (HCl) were mixed. After dip-coating and drying at 60 °C, the coated slides were calcined at 350 °C in air to remove the SDA. The coatings were characterized by XRD, TEM, sorption measurements as well as mechanical testing by a nanoindenter. The cell viability properties were tested with human fibroblasts and human umbilical vein endothelial cells (HUVEC). The coatings were further functionalized with sulfonate groups by grafting and loaded with the drug ciprofloxacin. Drug release experiments in PBS were performed over two weeks, the released amount of the drug was measured by a photometer.

RESULTS AND DISCUSSION

We were able to establish novel coatings based on BTEB-PMO with uniform mesoporous structure (Fig. 1) in which the organic linkers are embedded in the walls of the silica network. These coatings are more flexible and less hydrophilic than their pure silica counterparts. The calcined, the sulfonate-modified as well as the drug-loaded PMO coatings show a good biocompatibility in cell culture experiments (Fig. 2). First drug release experiments with ciprofloxacin from PMO coatings show promising results in antibacterial activity tests. After the modification of the coatings with sulfonate groups, the loaded and the released amount of the drugs can be increased two-fold.

Fig. 1: TEM image of a PMO coating with 9 nm pores that are oriented perpendicular to the substrate surface.

Fig. 2: Proliferation of human fibroblasts. The PMO coatings show good cytocompatibility.

CONCLUSION

PMOs coatings present a viable alternative to the well-characterized nanoporous silica bioactive films¹⁻³ and can – due to their good biocompatibility – be further developed as a novel biomaterial. Based on different PMOs precursors, it should be possible to adjust varying chemical properties, like pore size or hydrophobicity. In addition, the benzene units in the organic linkers offer interesting opportunities for further functionalizations, which can be useful for the binding of proteins or in drug release applications.

INTRODUCTION

In this work, interconnected porous materials was obtained by a new foaming method based on the combination of two steps. Initially, a stable physical foaming was induced using a surfactant (i.e. pluronic) as blowing agent of a homogeneous blend of polysaccharide and polyethylene glycol diacrylate solution [1]. Furthermore, the porous structure of the foam was chemically stabilized by radical polymerization induced by homogeneous heating of the sample in a microwave. Microwaving curing allow the foam formation, employing short reaction times [2]. This method is competitive if compared to any commercial process, and it is able to obtain natural polysaccharides-based foams.

EXPERIMENTAL METHODS

Different mixtures of a natural polysaccharides and polyethylene glycol diacrylate were cured in a laboratory microwave oven into silicone vessels. Azobis(2-methylpropionamidine)dihydrochloride was used as thermoinitiator (TI). Both sodium salt of carboxymethylcellulose (CMCNa) and polyethylene glycol diacrylate (PEG) and chitosan (CS) and PEG mixtures were prepared with different PEG/polysaccharide ratios in order to investigate the properties of final material. The rheological properties for each mixture before the curing process were evaluated by viscosity measurements (ARES Rheometric Scientific). The influence of different ratios of PEG/CMCNa and PEG/CS in the final product was evaluated by different techniques. Firstly, chemical properties of each sample have been evaluated by spectroscopy analysis FT-IR, before and after curing in order to maximize reaction yield, and optimize the kinetic parameters (i.e. time curing, microwave power). The mechanical properties of the final product were evaluated by the calculation of the elastic modulus. Porous structure and surface analysis were characterized by SEM. Water absorption capacity and stability of materials was evaluated by means of in-vitro degradation test in PBS media. Finally, preliminary biological characterization was carried out with the aim to prove the biocompatibility of the resulting material.

RESULTS AND DISCUSSION

During the foaming procedure, the solutions increased in volume at least by 100% of the initial volume after addition of Pluronic. All the foams with a lower PEG/polysaccharide ratio are homogeneous and stables. In contrary, the solutions with a higher polysaccharide concentration present increased viscosity, resulting in more stable foam. Based on spectroscopy analysis FT-IR, it is evident that the reaction is not complete. Therefore it was added a post-cure in oven at 45°C for

12 h that has improved reaction yield. Mechanical properties of the foam increase with the increased of the polysaccharide concentration. This is mainly due to the presence of physical entanglements resulting in a higher degree of cross-linking. PEG/CS foams have higher mechanical properties than PEG/cellulose foams. Fig. 1a shows the SEM image of foam 20P80CS2. It is evident a hierarchical structure with open pores of different size in all the composition. The results of the indirect contact assay (alamarBlue) after 24 h exposure of the cells to the supernatants from the leaching studies did not show a significant release of toxic compounds. In fact, the cells exposed for 24 h to eluents (3 days) reached values similar to the negative control. Moreover, the results of the direct tests are shown in figure 1b. There is a clear indication that the scaffold materials have no negative effect on the metabolic activity of the cells. Cell viability and proliferation increase in a statistically significant manner with culture time. Moreover, it is possible to observe that even if 20P80C2 material shows low values of alamarBlue at day 1, it becomes higher at 4 and 7 days, probably due to the presence of a greater amount of cellulose in the material that improves the cell proliferation

Figure 1. SEM micrography of 20P80CS2 sample (a). Cell proliferation short time 1,4 and 7 days for different blends of PEG/CMCNa(2%) (b).

CONCLUSION

This work demonstrated that physical foaming followed by thermo-polymerization induced by microwave is a quick and cheap foaming method to create structures with interconnected open porosity. The suitability to use two different polymer backbones has been successfully evaluated. Moreover, the preliminary biological analysis demonstrated the excellent biocompatibility profile.

INTRODUCTION

Carbonate apatite (CO₃Ap) block and granular prepared based on dissolution-precipitation reaction using calcite as precursors were found to be replaced to bone¹. However, the replacement to bone takes time. One of the methods to accelerate bone replacement may be to separate the role of surface and core materials of the bone substitute. In other words, the surface material is expected to show good osteoconductivity and should dissolve at weak acidic condition formed by the osteoblasts but should not dissolve at physiological condition. In contrast, the core materials should show higher dissolution than surface materials. In the present study, CO₃Ap coated calcite was fabricated and its behaviour at the bone defect was evaluated using rabbits

EXPERIMENTAL METHODS

Calcite block, one polymorph of CaCO₃ was prepared by exposing Ca(OH)₂ compacted uniaxially at 5MPa to CO₂ at room temperature for 7 days. Calcite granular, 600-1000µm, was immersed in 1 mol/L Na₂HPO₄ solution for prescribed period. Composition was evaluated by means of x-ray diffraction. Also, SEM and EDAX were used to observe the morphology and elemental analysis.

Cylindrical bone defects (φ5.0 mm×8.0 mm) formed at rabbit femur were reconstructed with 1) CaCO₃, 2) 10wt% CO₃Ap coated CaCO₃, 3) 30wt% CO₃Ap coated CaCO₃, 4) CO₃Ap. Also sham operation was made for comparison. Rabbits were sacrificed 4 weeks after surgery and analyzed by means of microcomputed tomography (microCT; Latheta LCT-200, ALOKA). Histological observation (MMA embedded; Villanueva-Goldner staining, Toluidine blue staining) was used to quantify volume of new bone at the defect site.

RESULTS AND DISCUSSION

Fig 1 summarizes the compositional transformation from calcite to CO₃Ap as a function of time at 40°C, 60°C and 80°C. As shown, calcite transforms to CO₃Ap and the rate of transformation was faster at higher temperature. 4 and 16 hours at 40°C were chosen to fabricate 10 and 30wt% CO₃Ap coated calcite. EDAX analysis confirmed that surface and core were CO₃Ap and calcite, respectively.

No inflammatory response was observed regardless of the composition of granular. Resorption was observed for all granules regardless of the composition of the granular. Resorption was remarkable in the case of calcite. 10wt% CO₃Ap coated CaCO₃ showed statistically higher resorption when compared to 30wt% CO₃Ap and CO₃Ap. Osteoclasts

Fig 1 Compositional transformation from calcite to CO₃Ap as a function of time.

found on the surface of 10wt% CO₃Ap coated calcite was largest whereas those on the surface of CO₃Ap was smallest. Since resorption was largest in the case of calcite, most of the resorption of calcite is thought to be caused by physico-chemical dissolution rather than osteoclastic resorption.

New bone formation was observed on the surface of all granular including calcite. However, the amount of newly formed bone was limited in the case of calcite. Interestingly, approximately twice the amount of new bone was observed in the case of 10wt% CO₃Ap coated calcite and 30wt% CO₃Ap coated calcite when compared to CO₃Ap. Although the mechanism of the larger amount of bone observed for the CO₃Ap coated calcite has not been clarified in the present study, Ca²⁺ supplied by the dissolution of calcite may elicit the activation of osteoblastic cells.

CONCLUSION

CO₃Ap coated calcite was found to be fabricated based on the regulation of dissolution-precipitation reaction time of calcite granular in Na₂HPO₄ solution. CO₃Ap coated calcite seems to have good potential to be ideal bone substitutes since it has higher osteoconductivity and shows quicker replacement to bone when compared to CO₃Ap.

Polysaccharide based nanocarriers for antioxidants

Ornella Bossio,¹ Laura G. Gómez-Mascaraque,^{1,2} Mar Fernández-Gutiérrez,^{1,2} Blanca Vázquez-Lasa,^{1,2}

Julio San Román^{1,2}

¹Institute of Polymer Science and Technology, CSIC. C/Juan de la Cierva, 3 28006 Madrid, Spain

²CIBER-BBN, Health Institute Carlos III. C/ Monforte de Lemos 3-5, 28029 Madrid, Spain, jsroman@ictp.csic.es

INTRODUCTION

The development of self-assembled nanoaggregate systems for antioxidants to improve their solubility and biocompatibility has received great attention in different fields such as biomaterials science.¹ Different hydrophilic and amphiphilic polysaccharides have been synthesized, chitosan (Ch) being one of the most used due to its genuine properties.² The aim of this work was the design and preparation of a nanocarrier for retinyl palmitate (RP) based on an amphiphilic chitosan (AmphCh) that can interact with the antioxidant. RP was selected due to its enhanced biological properties with respect to retinol and all-trans retinoic acid.

EXPERIMENTAL METHODS

Synthesis of the AmphCh was carried out by coupling reaction of palmitic acid (PA) mediated by 1-(3-dimethyl-aminopropyl)-3-ethylcarbodiimide (EDC) to get the Ch/P1 conjugate, and by the pair EDC/NHS (N-hydroxysuccinimide) to get the Ch/P2 conjugate. Nanoparticles (NP) of AmphCh either in presence or not of RP were prepared in distilled water at concentrations in the range 0.05 - 0.5 mg/mL. Physicochemical characterization was performed by FTIR and elemental analysis, and thermal characterization evaluated by TGA. Particle size distribution and zeta potential of NP were determined by dynamic light scattering (DLS) and morphology analysed by SEM, TEM and AFM techniques. Antioxidant behaviour was determined by the 1,1-diphenyl-2-picryl-hydrazyl (DPPH[•]) radical scavenging assay at 30 min. Biological studies were performed with fibroblasts of human embryonic skin.

RESULTS AND DISCUSSION

The coupling reaction of PA to chitosan proceeded successfully independent of reaction conditions, reaching yields of 89% and 95% for the synthesis of the Ch/P1 and Ch/P2 conjugates, respectively. Yield was only slightly higher for the synthesis using the pair EDC/NHS, but it allowed mild conditions. The amidation reaction was confirmed by analysis of FTIR spectra of amphiphiles, particularly in the regions 3000-2800 cm⁻¹ and 1650-1400 cm⁻¹. Substitution degree (DS) of chitosan calculated from elemental analysis gave values somewhat higher for Ch/P2 sample (10.3 %) compared with that of Ch/P1 sample (9.8 %). Free NH₂ groups of AmphCh determined by pH titration reduced from 68.5 % of initial Ch to 64.2 and 57.6 % for the Ch/P1 and Ch/P2 samples. The coupling reaction was also confirmed by thermal degradation analysis. Self-aggregated NP were formed by the association of the palmitoyl moieties (and RP in loaded NP) into

hydrophobic domains forming the cores and the chitosan backbones forming the hydrophilic outside shells. RP encapsulation was evident by FTIR spectroscopy. Loading efficiency (LE) values were 77.5 and 88.6 % and loading content (LC) values were 12.9 and 14.6 %, for the Ch/P1 and the Ch/P2 samples, respectively.

Values of apparent hydrodynamic diameter (D_h) were higher for Ch/P2 NP but they were similar for RP-loaded NP of both conjugates. Zeta potential (ζ) values reflected the positive charge of NP and stability in aqueous medium (Table 1).

Table 1. DLS results of NP. *2 mM NaCl solution.

NP	Conc. (mg/mL)	D _h (nm)	PDI	ζ (mV)
A	0.50	276±2	0.239±0.01	24.3±1.0
	0.10*	188±12	0.277 ±0.04	
B	0.50	437±8	0.213±0.04	26.1±0.8
	0.10*	466±11	0.259±0.05	
C	0.50	281±2	0.154±0.01	28.9±0.7
	0.10*	281±4	0.178±0.01	
D	0.50	274±19	0.310±0.01	28.9±0.3
	0.10*	328±3	0.304±0.02	

A: Ch/P1 NP. B: Ch/P2 NP. C: RP-loaded Ch/P1 NP.

D: RP-loaded Ch/P2 NP

Analysis of NP by SEM and AFM revealed an almost spherical morphology for all systems. NP examination by TEM confirmed the pseudo spherical morphology and the formation of the typical core-shell structure. DPPH[•] assay results gave a radical scavenging activity (RSA) of loaded NP of 33% for Ch/RP1 and 39% for Ch/RP2 samples. Unloaded NP had a RSA of 25%.

All NP were not cytotoxic, giving cellular viability values higher than 80 % in MTT tests. In addition, LDH assay results reflected no cytotoxicity via cellular membrane lysis. Uptake of RP-loaded NP was observed by endocytosis tests; however, blank NP did not enter the cells.

CONCLUSION

A palmitoyl chitosan conjugate is proposed as a suitable nanocarrier for RP with potential biomedical applications in areas such as skin diseases.

Effect of Kassinin and Collagen Fibrils on Cell Spreading and De-adhesion Dynamics

Edna George¹, Pradeep Kumar Singh¹, Samir Maji¹ and Shamik Sen^{1*}

¹Department of Bioscience & Bioengineering, Indian Institute of Technology (IITB), India ednasenlab@iitb.ac.in

INTRODUCTION

Amyloids are often associated with several diseases but studies have proved the importance of functional amyloids like curli proteins in *E.coli*, and Pmel17 in *H.sapiens* normal physiological functions of the host organisms. Additionally, amyloids have been proved to be non-toxic with high mechanical properties and tunable physio-chemical properties making them suitable candidate for tissue engineering application. Here, we studied the cell-amyloid interaction using Kassinin (Kas) which is a neuropeptide that belongs to tachykinin family¹. Lack of sufficient cell studies on Kas and the need for bio-friendly amyloids with desired mechanical properties to design suitable biomimetic matrices with natural topography led to the following study. We carried out cell studies using fibroblasts on kas coated substrates and compared the effects with collagen (Col) coated substrates to understand the cell spreading and contractile mechanics.

EXPERIMENTAL METHODS

Fibril preparation and Substrate coating: Kas fibrils were prepared as reported previously¹. For experiments, well-plates were incubated with Kas or Col (Sigma) at concentrations ranging from 0.5 to 7.5 μ M at 37°C for 2hrs. All the coated substrates were blocked with 2% F127 Pluronic (Plu) (Sigma) for 15min at room temperature and UV sterilized.

Cell Culture: NIH3T3 cells obtained from National Centre for Cell Science (NCCS, Pune) were maintained as instructed. Cells were harvested for experiments, seeded at a density of 4500cells/cm² and incubated for 24hrs at 37°C. For trypsin de-adhesion assay, cells were washed with 1x PBS, incubated with 0.25% trypsin-EDTA (HiMedia), and images were captured at 2s intervals at 10x magnification².

Image Analysis: All the images were analyzed using Image J software (NIH). ~100 cells for cell spread analysis and 30 cells for de-adhesion dynamics were pooled from two independent experiments for analyzing cell spread area, cell shape and retraction kinetics. For de-adhesion assay the cell spread area were traced as a function of time to obtain two time constants τ_1 and τ_2 . These values were normalized by fitting to a sigmoidal curve using Boltzmann equation².

RESULTS AND DISCUSSION

To exploit full potential of fibrils as a fully functional biomaterial, the extent of cell spreading were studied by analysing, phase contrast images acquired at 10x magnification (Fig 1A at $t=0$ sec). Fibroblasts showed a biphasic spreading response (Fig 1B) on Kas fibrils as well as on Col coated substrates across concentrations.

Additionally, the cell shape, which was measured as the circularity of the cell remained unchanged (data not shown). The negative control (only Plu coated substrates) showed a significant difference in cell spread area and cell morphology.

Fig1. Comparison of cell spreading ($t=0$ sec), retraction kinetics and polarity by NIH3T3 cells on Kas and Col of varying densities. (* $p<0.05$)

Significant difference in the spreading response between cells on Kas and Col suggested the probability of substrate dependent changes in biophysical properties of fibroblasts. Thus, we decided to probe the retraction kinetics of cells using trypsin de-adhesion assay. Here the changes in cell area were traced till the cells rounded up but remained attached to the substrate (Fig 1A). The de-adhesion dynamics showed that fibroblasts were more contractile (Fig 1C & D) and highly polarized on Col than on Kas fibrils (Fig 1E) irrespective of ligand density.

While blocking with Plu ruled out any possible effect of serum protein deposition that could enhance cell adhesion, unperturbed collagen deposition across all conditions (data not shown) eliminated the possible intervention of collagen secreted by fibroblasts. Hence, all the cellular and morphological changes were attributed to the effect of amyloid fibrils.

CONCLUSION

In conclusion, our studies demonstrate that kassinin can serve as a suitable biomaterial for tissue engineering applications. Long term studies on cells will help to understand the influence of kassinin on cellular processes like differentiation.

Fast Acting Antibacterial 45S5 Bioglass® Scaffolds Reinforced with Gelatin/Genipin for Bone Tissue Engineering

Wei Li^{1*}, Hui Wang², Seema Agarwal² and Aldo Boccaccini¹

^{1*}Institute of Biomaterials, University of Erlangen-Nuremberg, Erlangen, Germany, wei.li@ww.uni-erlangen.de

²Macromolecular Chemistry II, University of Bayreuth, Bayreuth, Germany

INTRODUCTION

45S5 Bioglass® is a promising material for bone tissue engineering scaffolds due to its excellent bioactivity, biocompatibility, osteogenic and angiogenic effects¹. However, uncoated 45S5 Bioglass® scaffolds exhibited insufficient mechanical properties². In addition, the risk of infection exists during scaffold implantation. Therefore, in order to improve the mechanical properties and incorporate antibacterial functionality, 45S5 Bioglass® scaffolds were coated with genipin crosslinked gelatin, and then loaded with antibacterial polyguanidine (poly(p-xylyleneguanidine)hydrochloride, PPXG)³.

EXPERIMENTAL METHODS

45S5 Bioglass® scaffolds were prepared by foam replication method². The obtained scaffolds were coated with 5% w/v gelatin-genipin (99:1) solution by dip coating method. PPXG loading was achieved by dripping the PPXG-methanol solution (40, 120 and 200 µg/mL) onto genipin crosslinked gelatin (GCG) coated scaffolds.

The morphology, structure and mechanical properties of scaffolds were characterized using SEM, FTIR and compression test. Simulated body fluid (SBF) was used to assess the bioactivity of scaffolds. Antibacterial activities to *E. coli* and *B. subtilis* were determined using Kirby-Bauer-Test and Time-dependent Test.

RESULTS AND DISCUSSION

Figure 1 shows that highly interconnected pore structure of scaffolds was maintained after coating. The strut was covered by a thin layer of gelatin. The porosity and pore size were 93% and 200-550 µm, respectively.

Figure 1: SEM images of GCG coated scaffolds.

The average compressive strength of uncoated and coated scaffolds was 0.04 MPa and 1.00 MPa, respectively. The area under the load-displacement curve of uncoated scaffolds was only 5 N·mm, whereas it was increased to 285 N·mm for coated scaffolds.

Figure 2: Typical stress-strain curves of uncoated and coated scaffolds.

The strengthening and toughening effects of GCG coating could be explained by micron-scale crack-bridging mechanism.

The FTIR spectra and SEM image of coated scaffolds show characteristic P-O and C-O bands of carbonated hydroxyapatite (HCA) and globular, cauliflower-like apatite crystals after 7 days immersion in SBF (Figure 3). The results indicate the retention of bioactivity of scaffolds after GCG coating.

Figure 3: FTIR and SEM showing HCA formation.

As shown in Figure 4, PPXG provided antibacterial activity to the scaffolds against both Gram-positive and Gram-negative bacteria. The speed of antibacterial action varied on the amount of PPXG. Sample (3) and (5) killed 99.9% *B. subtilis* after 120 and 30 min, respectively.

Figure 4: (1) uncoated scaffold, (2) coated scaffold, (3) coated scaffold + 10 µg/mL PPXG, (4) coated scaffold + 30 µg/mL PPXG and (5) coated scaffold + 50 µg/mL PPXG.

CONCLUSION

Improved mechanical properties were provided to 45S5 Bioglass®-based scaffolds by genipin crosslinked gelatin coating without sacrificing the *in vitro* bioactivity. Additionally, the scaffolds were made antibacterial against both Gram-positive and Gram-negative bacteria by using polyguanidine. The novel antibacterial bioactive 45S5 Bioglass®-based scaffolds with improved mechanical properties are promising candidates for bone tissue engineering.

INTRODUCTION

Understanding cell behaviour on synthetic surfaces is of foremost interest to engineer microenvironments that direct cell fate. As cells cannot interact directly with synthetic biomaterials, surfaces have been functionalized with a broad range of proteins, fragments, peptides and growth factors. However, these passive coatings can by no means provide the dynamic stimuli required to orchestrate cell responses and organise the formation of a new tissue at the material interface. Significant efforts have focused on engineering materials that recapitulate characteristics of ECM, such as the presentation of cell adhesive motifs or protease degradable cross-links, in order to direct cellular responses¹. However, the development of a cell/material interface able to provide biological stimuli upon demand has not been established yet. We hypothesised that non-pathogenic bacteria can provide such a role, as they can colonise the surface of a broad range of materials and can be genetically modified to express or secrete desired adhesive proteins or factors to a living cell population, upon demand. This work investigates the potential of a living interface based on *Lactococcus Lactis* expressing a FN fragment (FNIII₇₋₁₀) as a membrane protein to direct cell adhesion, signalling and differentiation². This system introduces engineered bacteria as a new tool to direct cell behaviour at the material interface.

EXPERIMENTAL METHODS

The GFP-containing pGFP-C2 plasmid was used to construct a vector with FNIII₇₋₁₀ downstream to GFP. FNIII₇₋₁₀ fragment was amplified from pET15b-FNIII₇₋₁₀ and cloned into the PT1NX plasmid. Transformed bacteria were cultured to establish a stable biofilm on glass surfaces. Biofilm viability was evaluated and observed using SEM and AFM. The surface density of FNIII₇₋₁₀ was quantified using ELISA with monoclonal HFN7.1 antibody and western-blot. C2C12 myoblasts were cultured on the living interface for up to 4 days. Cell adhesion and signalling was investigated by staining focal adhesions (vinculin) and FAK phosphorylation (western blot). Cell differentiation was quantified by staining sarcomeric myosin.

RESULTS AND DISCUSSION

Engineering microenvironments to provide cells with dynamic cues, as occurs in the natural extracellular matrix, is a field of intensive research seeking to direct the differentiation of stem cells and advance in strategies for tissue repair and regeneration. We engineered food-grade *Lactococcus* to present the FNIII₇₋₁₀ fibronectin fragment as a membrane protein,

containing RGD and PHSRN synergy sequences and promotes cell adhesion and differentiation (Fig. 1).

Figure 1. Schematic of the living biointerface. C2C12 myoblasts differentiated to myotubes on this system.

Cells adhere, spread, develop focal adhesions and promote the FAK phosphorylation on the FN-expressing *L. Lactis*, in a similar way as when seeded directly on a FN coating.. The myogenic differentiation triggered by *L. Lactis*-FNIII₇₋₁₀ strain was found higher compared to the non FN-expressing control strain and higher than on standard myogenic differentiation substrate (collagen I and native fibronectin coatings).

CONCLUSION

We have shown that non-pathogenic bacteria based on *L. Lactis* expressing the FNIII₇₋₁₀ fragment form a dynamic biointerface between synthetic materials and cells. Overall, this living interface enhances the myogenic differentiation process. Further genetic modification of this living interface is being done to engineer a dynamic system able to provide cells different temporal stimuli beyond cell adhesion, such as the delivery of growth factors and other molecules upon external demand, which can be then applied to several strategies to promote tissue repair and regeneration.

Self-Disinfecting Urinary Biomaterials: pH-Triggered Quinolone Release for Prevention of Catheter-Associated Urinary Tract Infections

Colin P. McCoy, Nicola J. Irwin, Christopher Brady, Louise Carson, David S. Jones, Sean P. Gorman
School of Pharmacy, Queen's University Belfast, 97 Lisburn Road, Belfast BT9 7BL, Northern Ireland, UK
n.irwin@qub.ac.uk

INTRODUCTION

The urinary tract, a common site of action of the quinolones, maintains a normal physiological pH range between pH 4.8 to pH 8¹. Elevations in urine pH to levels up to pH 9.1 are, however, reported during catheter-associated urinary tract infections (CAUTIs) as a result of urease-catalysed hydrolysis of urea into ammonia². In this study, we, firstly, examined the effect of pH on quinolone activity against the urease-producing pathogen *Proteus mirabilis*, and, secondly, exploited this bacterial-induced pH elevation in the development of infection-responsive candidate catheter coatings capable of releasing quinolone agents, specifically, and rapidly, at the onset of CAUTIs.

EXPERIMENTAL METHODS

Determination of antimicrobial susceptibility

Minimum inhibitory concentration (MIC), minimum bactericidal concentration (MBC) and minimum biofilm eradication concentrations (MBEC) of three quinolone agents: nalidixic acid, norfloxacin and ciprofloxacin, against *P. mirabilis* ATCC 35508 at pH 5, 7, 9 and 10 were determined according to Clinical and Laboratory Standards Institute methods.

Development of a chemically-triggered release system

A series of novel polymerisable ester nalidixic acid conjugates with varying vinyl chain lengths: 1-ethyl-7-methyl-4-oxo-1,4-dihydro-1,8-naphthyridine-3-carboxylic acid- (NAL-) 2-propen-1-ol ester, NAL-3-buten-1-ol ester and NAL-9-decen-1-ol ester, herein referred to as NAL2yl, NAL3yl and NAL9yl, respectively, were synthesised *via* a two-step procedure, involving preparation of a reactive anhydride intermediate, and subsequent esterification with a range of deprotonated vinyl alcohols: 2-propen-1-ol; 3-buten-1-ol; and 9-decen-1-ol. Drug conjugates (5% w/w) were copolymerised with 2-hydroxyethyl methacrylate before examination of release kinetics and resistance to adherence of *P. mirabilis* and *Staphylococcus aureus* in universal buffers of pH 7 and pH 10.

Statistical analysis

The effect of pH on antibacterial activity, drug release rates and bacterial resistance of the copolymers was statistically evaluated by a one-way analysis of variance, followed by Tukey's post-hoc test.

RESULTS AND DISCUSSION

All concentrations of nalidixic acid above the MBC displayed bactericidal activity selectively at alkaline pH, in contrast to the loss of cidal activity characteristic of high drug concentrations in pH 5 and pH 7 media. Elevation of media pH also caused an increase in both bacteriostatic and bactericidal activities of the two fluoroquinolones tested against both planktonic and

biofilm-associated *P. mirabilis*; MBC and MBEC values for ciprofloxacin decreased approximately 6000-fold and 10-fold respectively between pH 5 and pH 9.

Fig. 1: The effect of pH on the mean (\pm S.D.) release of nalidixic acid from the conjugate copolymers at 37°C with shaking.

The *in vitro* pH-mediated kinetics of nalidixic acid release from the conjugate copolymers are shown in Fig. 1. A similar trend in release rate with respect to pH of the dissolution media was observed for all copolymers, irrespective of conjugate alkyl chain length. The ester bond mediating attachment of nalidixic acid to the alkyl spacer moiety was relatively stable at normal physiological urine pH - pH 7 - and therefore successfully delayed drug release from the copolymers, in contrast to the significantly more rapid rates of release demonstrated at the elevated pH typical of CAUTIs - pH 10. Adherence of *P. mirabilis* and *S. aureus* to p(NAL9yl-co-HEMA) was approximately 80% lower than to the p(HEMA) control after both 4 h and 24 h contact.

CONCLUSION

The observed increase in quinolone bactericidal activity in alkaline conditions provides rational for their use in the chemotherapy of urinary tract infections. Initial microbiological assessment suggests that the pH-responsive nalidixic acid conjugate copolymers developed herein hold significant promise for preventing CAUTIs when applied as urinary catheter coatings.

Apatite Promoting, Low Modulus Composite Bone Cements with Low Heat Generation upon Set and High Subsequent Antibacterial Release

Muhammad Adnan Khan, Anne Young

UCL, Eastman Dental Institute, 256 Gray's Inn Road, London WC1X 8LD. Email: adnan.khan.11@ucl.ac.uk

INTRODUCTION

Vertebral compression fractures (VCF) can be stabilized by PMMA cement (Simplex-P®). Inherent drawbacks, however, include long setting time to enable hand mixing. Furthermore, high heat generation during set and monomer leaching upon incomplete cure can kill cells¹. Moreover, PMMA does not promote apatite formation to enhance bonding to living bone. This is combination with shrinkage during set, limits bone fixation. Antibiotic release from PMMA is also restricted (5-7%)¹.

Recent clinical studies have demonstrated significant advantages of using the composite cement (Cortoss®) instead of PMMA for VCF fixation². Dimethacrylates use in Cortoss, instead of less cell compatible methyl-methacrylate (in PMMA) is of particular benefit. Furthermore, composites can be mixed in seconds and dimethacrylate conversion need only be 50% rather than 100% to prevent monomer leaching. Cortoss also produces significantly less heat and shrinkage upon set and may promote low or negligible level apatite precipitation on surface. Cortoss, however, exhibits high modulus with lower strength and toughness³ than PMMA and is therefore less able to absorb energy before breaking. Cortoss has no antibacterial release or effect.

The aim of this study was therefore to compare curing and mechanical properties of experimental composites with those of Cortoss® and Simplex® and demonstrate their apatite-precipitation-enhancing and antibacterial-release features.

EXPERIMENTAL METHODS

UDMA, TEG-DMA dimethacrylate monomers were combined with initiator (BP) or activator (DMPT) to form two liquid phases. Two stable pastes were prepared by mixing with glass particles containing chlorhexidine (10%) (CHX), reactive mono and tri calcium phosphate (CaP – 10 or 20%) and a polymeric antimicrobial (PAM – 0 or 10%) (Table 1). FTIR was used to assess the time for half reaction and final conversion after mixing of the two pastes. The latter were used to calculate heat generation and shrinkage. Biaxial flexural strength (BFS) and modulus were measured. CHX and PAM

	CaP wt%	PAM wt%
F1	20	10
F2	10	10
F3	10	0
C	Cortoss®	
S	Simplex®	

Table 1: Formulations

release were assessed using UV and HPLC. Apatite precipitation on set material surfaces in simulated body fluid was quantified using mass change and confirmed using SEM, EDAX and Raman.

RESULTS AND DISCUSSION

The working time for all experimental material were comparable with Cortoss. Subsequent setting time (Half-life) of F1 and F2 was comparable with Cortoss but much lower as compared to Simplex. This reduces possibility of monomer leaking from the site of application in vivo. The final conversion was higher for all experimental formulations (74-80%) than for Cortoss (64%) (Table 2). This reduces subsequent potential monomer leaching. Heat generation and shrinkage of experimental material were beneficially lower than commercial. Although the strength of F1 and F2 were lower than Cortoss, their low modulus will improve toughness (Table 2) and potentially decrease the chance of brittle fracture in adjacent vertebra⁵. PAM release is 8-10 times faster than CHX and nearly 95% in 6 weeks (Fig-1). PAM also increases the release of other antibacterial component. Watersorption for all formulation is 1-3% of mass change. However, mass change for F1 and F2 is significantly increased due to hydroxyapatite formation on the material surfaces (Fig-2). SEM images shows

No.	Half life (t ₅₀) (s) 95%-CI	Final conversion (%) 95%-CI	Heat (cal/cc) 95%-CI	Shrinkage % (vol/vol) 95%-CI	Flexural strength (MPa) 95%-CI	Modulus (Gpa) 95%-CI
F1	265 ±5	79.6 ±0.6	26.4 ±0.3	4.3 ±0.02	60 ±2	1.1 ±0.1
F2	255 ±7	79.4 ±0.5	26.1 ±0.3	4.3 ±0.02	74 ±2	1.5 ±0.1
F3	300 ±5	74.1 ±0.6	25.1 ±0.3	4.2 ±0.02	115 ±4	2.3 ±0.2
C	310 ±5	64 ±0.5	30.1 ±0.3	5.0 ±0.02	99 ±4	3.3 ±0.3
S	402 ±17	81 ±0.2	46.8 ±0.3	7.6 ±0.02	128 ±4	1.7 ±0.3

Table 2: Half-life, final conversion, heat generation, mechanical properties of experimental and commercial materials.

Figure 1: PAM and CHX release from F1 and F2.

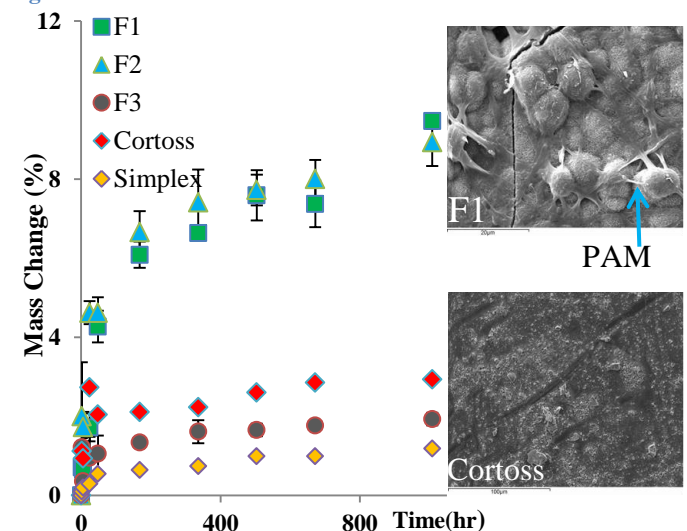

Figure 2: Mass change due to water sorption and apatite formation on the surface of specimen in simulated body fluid (SEM images).

hydroxyapatite potentially held together by PAM strands.

CONCLUSION

Experimental formulations F1 and F2 have high conversion in addition to low heat generation and shrinkage that should improve biocompatibility and bonding. Their low modulus could also prevent adjacent vertebral fracture. PAM is readily released to provide antibacterial action but in addition promotes rapid apatite layer formation.

Surface post-modification of polylactide is combined to CuAAC click chemistry or thiol-yne click photochemistry to yield antibiofilm surfaces.

INTRODUCTION

As a direct result of the life expectancy increase, implants are increasingly used for the restoration of human anatomy and functions. However, this is accompanied with the development of biomaterial-associated septic failures¹. To limit these risks, the modulation of the antibacterial surface properties of prosthetic materials appears therefore as a convenient and efficient strategy. In this frame, post-polymerization modification approaches, especially click chemistry, have attracted much attention in the last decade². In this communication, we wish to report on the recent post-modification strategies developed by our group to yield polylactide antibacterial surfaces.

EXPERIMENTAL METHODS

PLA surfaces were activated via anionic chemical modification to anchor alkyne moieties, according to a reaction previously described by our group³. This clickable PLA intermediate was then engaged in two distinct strategies. In a first approach, well-controlled quaternized PDMAEMA chains (5-10 kDa) with an azide chain-end were synthesized and covalently grafted to the PLA clickable surfaces by CuAAC 1,3-dipolar cycloaddition. In a second approach, cationic derivatives of α,β -poly(N-2-hydroxyethyl)-aspartamide (PHEA) were functionalized with lipoic acid (LA). Photoactivated thiol-yne reaction was done under UV by reacting PHEA-LA at the surface of the clickable PLA in the presence of TCEP. All polymers have been characterized by NMR and SEC analyses. After careful washes, surfaces were analysed by AFM and XPS. Antibacterial activity was tested against four bacterial strains. Adherence of bacteria and biofilm formation were tested. Cytocompatibility was evaluated with L929 fibroblasts. All data are expressed as means \pm SD and correspond to measurements in triplicate.

RESULTS AND DISCUSSION

Thanks to the use of optimized and mild activation conditions, alkyne functionalized PLA surfaces were obtained without degradation as already reported elsewhere⁶. CuAAC cycloaddition of QPDMAEMA chains was evaluated by XPS and showed an overall 10% coverage of the PLA surface by QPDMAEMA. No residual copper was detected. Activity was strong

against all bacterial strains, including *E. Coli* and *S. Aureus* with a clear dependence of the antibacterial activity over QPDMAEMA molecular weight and alkylating agent (Figure 1). Best results were obtained for Mn = 10 000 g/mol and heptyl group with adherence reduction factors > 99.999% (ASTM E 2149–01) and strong bactericidal activity.

Fig. 1. Antibacterial activity of antibacterial PLA surface (red bars) against four bacterial strains. PLA plates are shown as control (brown bars).⁴

With short reaction times and no metals used, UV photoactivated thiol-yne grafting of PHEA-LA was studied as a green alternative to CuAAC. Advantageously, the heterogeneous surface reaction took place in aqueous media. Various solvent mixtures were tested and best results were obtained in slightly acidic water/ethanol (1:1) medium, in the presence of TCEP and with a 15 min irradiation time per PLA plate side. Under these conditions, XPS confirmed the covalent grafting of the cationic PHEA-LA derivative. As for CuAAC, antibacterial and antibiofilm activities were tested with again reduction factors > 99.999% and up to 80% biofilm decrease for all four bacterial strains. Interestingly, whatever the methodology used all surfaces showed a good cytocompatibility towards L929 fibroblasts cells with respect to TCPS control.

CONCLUSION

Antibacterial PLA surface modification was obtained in an efficient two steps approach by combining anionic and click chemistries. For the first time green thiol-yne strategy was applied to PLA surfaces, which paves the way to further developments in the biomedical field.

INTRODUCTION

Antibiotics are still the most effective agents used to fight bacterial infections. Their administration to patients is generally through oral, topical or parenteral route; antibiotics are quickly metabolised or excreted from the human body, this leads to the need for frequent administration and their half-life is usually an important factor in the therapeutic choice. In order to render the administration less frequent, antibiotic release from a carrier can be employed. Gold nanoparticles have found numerous applications as drug delivery vehicle because of their stability and biological safety¹.

In this work, we synthesised gold nanoparticles capped with either glutathione or L-cysteine and covalently attached gentamicin to the capping agent.

EXPERIMENTAL METHODS

Conjugates preparation. Gold nanoparticles were synthesised from a HAuCl₄ water solution (17 mM) containing glutathione or L-cysteine (8 mM) as capping agent adding hydrazine. The nanoparticles were separated after 1 hour of mixing at room temperature adding methanol and centrifuging.

Conjugates were prepared dispersing the 100 mg of Au nanoparticles in 25 mM MES buffer (pH 6.5) in the presence of gentamicin (50 mg) along with NHS (25 mg) and EDC (45 mg). After 24 h at room temperature under vigorous mixing, the conjugates were separated through centrifugation and washing in methanol.

Gentamicin release quantification. Conjugates were dispersed in buffer pH=7 and incubated at 37 °C. At prefixed times samples were taken and the gentamicin in the buffer was quantified thorough fluorescence spectroscopy using o-Phthaldialdehyde.

Antimicrobial testing. *Staphylococcus aureus* (NCIMB 9518) and Methicillin resistant *S. aureus* - MRSA (NCTC 12493) were grown at 37 °C for 24h in Brain Heart Infusion (BHI) broth. Cells were diluted in fresh BHI broth to a concentration of 10⁴ CFU/ml prior to mixing with Au-gentamicin conjugates at various concentrations and then incubated at 37 °C. Cells were counted after 24 h through serial dilution and plating on BHI Agar.

RESULTS AND DISCUSSION

FTIR revealed that the hydrogen bond of the SH group present in both glutathione and L-cysteine disappeared after the synthesis of the gold nanoparticles demonstrating the stabilisation conferred to the nanoparticles by the strong affinity of gold for sulphur. Both capping agents exhibit carboxylic group that were employed for the conjugation of gentamicin that presents amino (NH₂) groups.

Gentamicin was released from the glutathione capped Au conjugates for two days, after 2 days no more bound

gentamicin was released. However when L-cysteine was used the released was completed after 24 hours. Furthermore, the over amount of antibiotic released was greater for glutathione capped conjugates than L-cysteine.

Figure 1. Bacterial cells survivors after 24h contact with gold conjugates at various concentrations.

No antimicrobial activity was exhibited by the unconjugated nanoparticles at concentrations as high as 3.5 mg/ml. The conjugates exhibited antimicrobial activity against *S. aureus* and MRSA (Fig 1). When glutathione was employed the MIC was 220 µg NP/ml irrespectively of the bacteria species tested. Whilst when cysteine was employed as capping agent the MIC was 440 µg NP/ml for MRSA and 880 µg NP/ml for *S. aureus*.

The MIC for pure gentamicin was 4 µg/ml for MRSA and less than 2 µg/ml for *S. aureus*, therefore, the higher resistance of *S. aureus* to the conjugates is not related to the antibiotic used but is connected to interference of cells growth with the antibiotic release from the carrier, possibly through pH changes of the media. Moreover, the higher activity of the glutathione capped conjugates is related to the higher amount of gentamicin released from these nanocarriers.

CONCLUSION

This work demonstrates that gold nanoparticles can be employed as antibiotic carriers providing a continuous release of antibiotic over few days. Glutathione appeared a better capping agent than cysteine allowing higher load of gentamicin resulting in lower minimum inhibitory concentrations of the conjugate against both MRSA and *S. aureus*.

Plasma nanofilm as biocompatible and antibacterial coating for biomaterials

Michael Bergmann, Sebastian Lickert, Loic Ledernez, Gregory Dame and Gerald Urban

Department of Microsystems Engineering, Albert-Ludwigs-University of Freiburg, Georges-Köhler-Allee 103, 79110, Freiburg, Germany, michael.bergmann@imtek.de

INTRODUCTION

In the development of biocompatible materials for biomedical applications and biosensors the foreign body response is an important issue. [1] The healing of surrounding tissue often interferes with the function of an implanted biomaterial. Events like protein deposition, hemostasis, inflammation, tissue repair, infections and the encapsulation of the functional part of the implant are the main cause of failure of the implanted device. [2]

EXPERIMENTAL METHODS

In this study biocompatible nanofilms are produced by means of a plasma polymerization process using a low-pressure magnetron-enhanced 15 kHz glow discharge. [3] This process allows the precise control of the film nature and behaviour. The resulting hydrocarbon film has a thickness of a few nanometer and keeps therefore the inherent properties of the substrate material. X-ray photoelectron spectroscopy, dynamic contact angle, Fourier transformed spectroscopy and electrical impedance spectroscopy were used to investigate the chemical and physical properties of these nanofilms. Measurements on protein adsorption gave the possibility to tailor the thin films in the needed direction.

RESULTS AND DISCUSSION

The nanofilms were investigated using different surface analytical methods. Also the interaction in contact with different biological sample materials was tested in-vitro. The precise measurement of the adsorbed proteins indicated a native secondary structure of proteins on these surfaces.

Different in-vivo sensor dummies which are in contact with blood and soft-tissue were coated by these nanofilms. The explanted sensors were kept free of any encapsulation by this coating. This stands in good correlation with the measurement of adsorbed proteins. Additionally the nanofilms are equipped with an antibacterial property which minimizes the risk of post-operative infections.

Fig. 1: coated (lower) and uncoated (upper) PDMS-Stripes after 6 weeks of implantation

CONCLUSION

The first in-vitro results of the adsorption of blood proteins indicated already a very biocompatible character of these nanofilms. The explanted sensors were kept free of any encapsulation by this coating. These ground breaking coatings can open the door for many new applications in the field of in-vivo sensors but also other biomedical products.

Fluoride-Containing Bioactive Glasses – from Structure to Cell Compatibility

D. S. Brauer^{1*}, E. Gentleman², R. G. Hill³ and N. Karpukhina³

^{1*}Otto Schott Institute of Materials Research, Friedrich Schiller University Jena, Germany, ²Craniofacial Development & Stem Cell Biology, King's College London, UK, ³Dental Physical Sciences, Queen Mary University of London, UK, delia.brauer@uni-jena.de

INTRODUCTION

Bioactive glasses (BG) bond with living tissue *via* formation of a surface apatite (Ap) layer and release therapeutically active ions. Fluoride (F) is known for its ability to prevent dental caries, and it also enhances bone formation [1], but owing to a narrow therapeutic window [2] its use in osteoporosis treatment had been dismissed. Recent meta analyses, however, have shown that F is efficacious at very low doses [3]. This opens the possibility of creating biomaterials that release F at appropriate levels to influence cell activity. We have incorporated F into BGs while keeping their silicate structure constant. This allowed us to examine the effects of low, controlled F release from BGs on osteoblasts without the complication of changes in glass structure.

EXPERIMENTAL METHODS

BG Preparation and Structural Analysis: BGs (SiO_2 – P_2O_5 – CaO – Na_2O – CaF_2 ; 0 to 18mol% CaF_2) were produced *via* a melt–quench route. CaF_2 was added while the ratio of all other components was kept constant. Glass structure was characterised using ^{29}Si , ^{31}P and ^{19}F MAS NMR spectroscopy.

Cell Culture: Prior to cell culture experiments, BG discs (1cm ϕ , 1mm height) were pre-conditioned in culture medium for 4 days. BG discs were seeded with human osteosarcoma cells (Saos-2) at 30,000 cells/cm² and cultured for up to 28 days. Cell viability was visualised by LIVE/DEAD[®] staining. Alkaline phosphatase (ALP) activity was measured using p-nitrophenyl phosphate. Statistical analyses were carried out using ANOVA with post-hoc Tukey test; $p < 0.05$ indicated statistical significance.

Ion Release and Apatite Formation: F released into the culture medium was analysed using a fluoride-selective electrode. Ap formation on the discs was analysed using X-ray diffraction (XRD) and scanning electron microscopy (SEM).

RESULTS AND DISCUSSION

Fluoride did not disrupt the silicate network (by forming Si–F bonds) but complexed Ca^{2+} and Na^+ instead. Therefore, by adding CaF_2 (rather than substituting for CaO), the silicate network structure was kept constant (Fig. 1). Phosphate in the glass was present as orthophosphate (no Si–O–P), allowing for phosphate release upon contact with fluids.

The CaF_2 -free BG formed Ap at later time points than CaF_2 -BGs (Fig. 2a), caused by formation of the less soluble fluorapatite (FAp) with F released from CaF_2 -BGs (Fig. 1) [4]. All CaF_2 -BGs formed Ap within less than a week according to XRD. Detectable F-release

occurred during the first few days of culture only, owing to the low-solubility FAp surface layer formed.

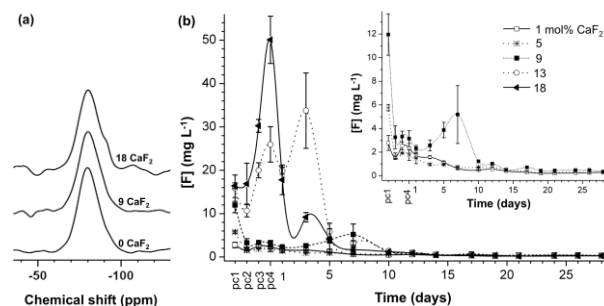

Figure 1: (a) ^{29}Si MAS NMR spectra of BG; (b) F release from BGs into culture medium.

Cells proliferated more extensively on low- CaF_2 BGs, while higher CaF_2 BGs promoted the formation of nodular structures (Fig. 2b). High- CaF_2 BGs also promoted significantly greater ALP activity per cell than low [5], suggesting that high- CaF_2 BGs stimulate osteoblast differentiation and mineralisation, likely through higher initial F-release.

Figure 2: (a) SEM images of BG surface at 7 and 14 days and (b) LIVE/DEAD[®] staining of cells at 14 and 28 days. (Scale bars (a) 3 μm and (b) 500 μm)

CONCLUSION

By adding CaF_2 (rather than substituting for CaO) BG silicate structure and thus degradation and ion release are maintained, thereby enabling F-releasing BG to promote osteoblast activity. The combination of controlled F-release with the known benefits of BGs may make these materials of interest for a range of bone regeneration applications.

Atomic structure of Mg-based metallic glasses for biomedicine

Jamieson Christie*

*Department of Chemistry, University College London, U.K., jamieson.christie@ucl.ac.uk

INTRODUCTION

Mg-based alloys are often used for biomedical implantation, especially for orthopaedic applications, as they have similar density and Young's modulus to human bone. However, on implantation into the body, these alloys can corrode and release hydrogen gas, which is potentially harmful to the patient.

In 2009, certain compositions of Mg-Zn-Ca bulk metallic glasses were found to form a passivating layer on their surface, which prevented the release of hydrogen gas¹. This opened up the possibility to use these glasses as orthopaedic implants.

The atomic mechanism behind the formation of this layer is still unknown. To design and optimise these glasses for orthopaedic applications will require detailed knowledge of their atomic structure and mechanical properties, as well as an understanding of the processes which lead to the formation of the passivating layer. In this new project, we use computer simulations to understand the properties of these glasses and suggest directions for their optimisation.

EXPERIMENTAL METHODS

Molecular dynamics methods have been used to understand the structure and properties of many forms of glasses, including metallic glasses, and bioactive glasses. In particular, the bulk structure of bioactive silicate-based² and phosphate-based glasses³ is known to be very important in determining their behaviour on implantation into the body. We intend to use the same techniques that have elucidated the behaviour of these bioactive glasses to look at metallic glasses.

Models of Mg-Zn-Ca glass compositions which both do and do not form the passivating layer were prepared using first-principles Born-Oppenheimer molecular dynamics (MD) through the CP2K code⁴. The models are initially equilibrated at 1500 K, and then cooled down at a high cooling rate, before simulation at constant volume and temperature at ambient conditions. All data presented are averaged over this room-temperature run. The advantage of first-principles MD is that no empirical expression for the interatomic forces is required. The disadvantage is the high computational expense, which means that only small models (c.120 atoms) can be used.

RESULTS AND DISCUSSION

The local structure of the glass, in terms of bond lengths and coordination numbers, shows very little dependence on composition. Figure 1 presents the partial pair-correlation functions. As in other metallic glasses, icosahedra are present and identified based on their Voronoi signature⁵, but these are by no means the

dominant local structure. We infer that any structural differences occur at larger length scales, perhaps at the level of the packing of polyhedra, which are inaccessible to this level of simulations. Interatomic forces derived from these simulations will form the basis for the development of an accurate interatomic potential, using the “force-matching” method⁶, which will allow the simulation of larger systems.

Figure 1: Partial pair-correlation functions for $\text{Mg}_{60}\text{Zn}_{35}\text{Ca}_5$.

During the talk, we will outline progress made toward the development of these potentials, as well as the possibility to obtain experimental diffraction data.

CONCLUSION

Differences between Mg-Zn-Ca glass compositions which form and do not form a passivating surface layer do not occur at the level of nearest-neighbour coordination spheres. We conclude that experimental data and larger simulations are required to understand these systems fully.

INTRODUCTION

The aim of this work was to synthesise monodispersed bioactive glass nanoparticles, which will be used in three ways:

1. Incorporated into a degradable polymer matrix to form a scaffold for bone regeneration.
2. Intracellular delivery of active ions (e.g. Ca, Sr)
3. Biodegradable ultrasound contrast agents for cell therapy.

Bioactive glass scaffolds are bioactive, porous and biodegradable but are brittle. They can be toughened through hybrid synthesis^[1]. The degradable nature of the bioactive glass particles produced using this method is also desirable for therapeutic applications. Our previous studies show our bioactive glass particles can be uptaken by stem cells without affecting toxicity or stemness^[2]. Doping the particles with active ions can allow sustained intracellular delivery of these ions.

Silica nanoparticles are commonly produced by using the Stöber process^[2]. However, the introduction of calcium complicates the procedure^[3]. The aim was to revisit the Stöber process to understand monodispersed particle size control. Different methods of calcium incorporation and incorporation of additional elements were then investigated.

EXPERIMENTAL METHODS

Particle synthesis:

Using a modified version of the Stöber process^[2], ethanol, water and ammonium hydroxide were mixed in an ultrasonication bath. TEOS was then added. Once the particles reached their maximum size (determined by DLS) calcium nitrate was added. The solution was centrifuged to obtain the solid particles which were dried before being heated to 680 °C. The effect of reactant concentrations on particle size, shape and dispersity was investigated. The particles were then functionalized by leaving for 24h in a solution of APTES, ethanol and ammonium hydroxide to create NH₃ groups on the nanoparticle surface. Particles containing phosphorous and potassium were also obtained using diethyl phosphatoethyl triethoxysilane (DEPETES) and potassium nitrate.

Particle characterisation:

DLS and TEM were used to confirm the size and morphology of particles. ICP was used to determine the chemical composition of the particles and their degradation products in artificial lysosomal fluid (ALF). Zeta Potential measurements and FTIR were used to confirm the functionalization of particles.

RESULTS AND DISCUSSION

- Effect of reactants on particle size:

- Increased ammonia from 0.1 -2.5M resulted in an increase in particle size (Fig 1)
- Increasing water from 3 – 15M resulted in an initial increase and then a decrease in particle size.
- Varying TEOS over the range 0.17-0.28M had no effect on particle size.

Figure 1 TEM images of silica particles produced using 0.28M TEOS, 6M H₂O and varying concentrations of ammonia A) 0.2M NH₃ B) 0.5M NH₃ C) 2M NH₃

- DLS results corresponded to TEM results for particles up to 300nm.
- Monodispersed particles from 20-500nm were synthesised containing 10mol% P₂O₅, 10mol% K₂O and up to 15mol% CaO.
- All particles were seen to degrade over time in ALF (Figure 2).
- Zeta potential of particles was seen to change from -20mV to +20mV due to functionalization.
- Functionalisation allows covalent coupling to a biodegradable polymer (e.g. gelatin) matrix.

Figure 2. Silica particles doped with P and K before and after incubation for 45 days

CONCLUSION

By splitting the synthesis process into 3 steps (1. Synthesis of silica nanoparticles, 2. Incorporation of additional elements e.g. Ca, 3. Functionalisation) it enables functionalised, monodispersed nanoparticles of various compositions to be produced for a variety of applications.

INTRODUCTION

Metastatic bone disease is a frequent complication of treatment-resistant cancers causing significant pain and disability to the patients. Treatment of bone metastases is challenging and treatment decisions are especially difficult in patients with painful osteolytic metastatic lesions of the pelvis and spine, for which percutaneous osteoplasty has been introduced as a treatment¹. This minimally invasive surgical technique involves percutaneous chemical, thermal or cryoablation of the tumor cavity, followed by defect filling with bone cement. The radioisotope of holmium (^{166}Ho) has a half-life of 26.8h, with max and average tissue penetration depth of 10.2 mm and 2.1 mm, respectively. We hypothesize that an injectable biodegradable composite with transient radioactivity of spatial limitation could be a useful component for percutaneous osteoplasty in selected subgroups of patients. As a part of tumor ablation, it could kill the remaining cancer cells and ensure efficacy of local tumour control. The physical properties of ^{166}Ho could be optimal for targeted radiotherapy with minimal effect on surrounding healthy cells. In this study, we examined the *in vitro* tumor-killing efficacy of radioactive ^{166}Ho containing silica sol-gel glass granules.

EXPERIMENTAL METHODS

Holmium encapsulated silica (SiO_2) sol-gel granules were designed and manufactured as described previously². Granules with diameter of 315 – 500 μm contained 99 wt% SiO_2 and 1 wt% holmium. The incorporated holmium was activated by neutron bombardment (Map Medical Technologies Ltd, Finland). Non-radioactive holmium containing sol-gel granules were used as the control.

The effect of non-radioactive granules on cell viability of human osteosarcoma (MG-63) and breast cancer (MCF-7) cells was explored using the alamarBlue® assay. Cells were cultured alone (Ctrl) or with different concentrations (12.5, 25 and 50 mg/ml) of non-radioactive sol-gel granules. Seeded cells were allowed to adhere for 24h before adding the granules. Seeding density was adjusted so that ctrl cultures reached confluency in 7 days. Cell viability was monitored at day 3, 7 and 14.

AlamarBlue® assay, disk diffusion assay, and clonogenic assay were applied to define the antitumor efficacy of ^{166}Ho containing granules. Cells were seeded according to previous experiment, with the constant concentration (12.5 mg/ml) of radioactive or non-radioactive granules. Cultures without granules served as controls. The mean ^{166}Ho activity of activated

granules was 0.6 MBq/mg. AlamarBlue® and disk diffusion assays were performed at 3, 7, and 14 days and the clonogenic assay at 7 days. Results are presented as mean \pm SD (n=6 for all conditions of both cell lines in each assay). Differences between the groups were tested with one-way ANOVA or non-parametric test (Mann-Whitney test) depending on distribution and homogeneity of variances.

RESULTS AND DISCUSSION

The osteosarcoma (MG-63) and breast cancer (MCF-7) cells developed confluent cultures around non-radioactive granules. Although there was a significant inverse correlation between increasing amounts of non-radioactive granules and cell viability, cells treated with the lowest concentration (12.5 mg/ml) of non-radioactive granules had viability equivalent to control without granules. These results showed that non-radioactive holmium encapsulated sol-gel glass granules are non-toxic to malignant cells.

The three assays demonstrated that ^{166}Ho encapsulated radioactive granules efficiently kill malignant cells *in vitro*. Based on cell viability, breast cancer cells had a later response to radiation compared to osteosarcoma cells. At 14 days, significant growth inhibition areas were detected around the radioactive granules (p=0.018 for MG-63 and p<0.001 for MCF-7). Radioactivity also significantly reduced the clonogenic properties of cancer cells, i.e. ability of individual cells to produce multiple offspring in subcultures. Survival fractions after radioactive treated were 54 \pm 32% for MG-63 (p=0.003) and 60 \pm 29% for MCF-7 (p=0.008), compared with the non-radioactive group.

CONCLUSION

Based on these *in vitro* results, ^{166}Ho containing silica sol-gel glass granules have the expected tumor-killing efficacy. This injectable bioresorbable material could be a valuable addition to percutaneous osteoplasty of bone metastases. After decay of the radioactivity, the composite could act as an osteoconductive material for restoration of the bone stock.

INTRODUCTION

Bone tissue engineering requires highly porous scaffolds with good mechanical stability, and preferably osteoconductive properties¹. Synthetic bioabsorbable polymers, like polyesters, are often used for the application, but they lack the required bioactivity on their own, and their acidic degradation products provoke an adverse tissue response. By adding bioactive glass (BaG) into the scaffolds the mechanical stability and osteoconductive properties can be improved. The addition of glass is thought to buffer the acidic degradation products of polyesters².

In this study we prepared novel poly(lactide-co-glycolide) 70/30 (PLGA)/BaG hybrids by freeze-drying. In total, two different compositions of PLGA and bioactive glass were used and two different hybrid scaffolds with porous PLGA component together with bioactive glass fibers were studied *in vitro*.

EXPERIMENTAL METHODS

Two different PLGA polymers with lactide-to-glycolide ratio of 70:30 were synthesized by ring-opening polymerization: PLGA1 with M_w of 76 000 g/mol and PLGA2 with M_w of 48 000 g/mol. The bioactive glass fibers (BaG1 and BaG2) were cut to staple fibers, and carded into mesh.

The PLGA was dissolved in 1,4-dioxane at concentrations of 5 wt% and 3 wt% for plain and hybrid scaffolds, respectively. The PLGA solution was frozen at -30°C for 24 h and afterwards freeze-dried for 24 h. The hybrid scaffolds were produced by adding the BaG fiber mesh into the PLGA solutions prior to freezing. Table 1 shows the studied scaffold types and their compositions.

Table 1. Studied scaffold types and their compositions.

Polymer scaffolds		Hybrids
PLGA1	PLGA1 5 wt%	PLGA1/BaG1 PLGA1 3 wt% + BaG1 mesh
PLGA2	PLGA2 5 wt%	PLGA2/BaG2 PLGA2 3 wt% + BaG2 mesh

All the scaffolds were gamma sterilized at 25 kGy. *In vitro* degradation studies for 10 weeks were carried out for six parallel samples. The dimensional stability of the scaffolds, scaffold composition (TGA), pore size of the

scaffolds (SEM, MicroCT), the ability of BaG to buffer the acidic degradation products of PLGA, contact angle measurements, and degradation rates (GPC, DSC) of the scaffolds were studied.

RESULTS AND DISCUSSION

Freeze-drying of structures in which a BaG mesh was incorporated into a PLGA matrix was found to be an applicable method to produce highly porous hybrid scaffolds.

The interconnection of BaG fibres into PLGA matrix was good (SEM imaging and MicroCT studies). The pore structure in the scaffolds was more homogeneous in PLGA/BaG hybrids than in plain PLGA scaffolds. Furthermore, the plain PLGA scaffolds contained bigger macropores. All scaffolds had a highly porous structure, with a porosity of over 90% (MicroCT studies).

BaG buffered the acidic degradation products of PLGA in the hybrid scaffolds during the hydrolysis (measured by pH change of solution). Also, dimensional change was moderate for PLGA/BaG hybrid scaffolds while the plain PLGA scaffolds shrank and twisted during the hydrolysis.

CONCLUSION

The used method to combine these two three-dimensional porous structures, highly porous PLGA and BaG into a hybrid, showed preferable structure for bone tissue engineering. The dimensional stability of the studied hybrids was improved by BaG fibers, and also the buffering effect of BaG of the acidic degradation products of PLGA was confirmed.

Development of Novel 45S5 Bioglass® Scaffolds with Fibrous Surface Morphology using Electroflocking Technology for Bone Tissue Engineering

Preethi Balasubramanian¹ and Aldo R Boccaccini¹

¹Institute of Biomaterials, Department of Materials Science & Engineering, University of Erlangen-Nuremberg, Germany
preethi.balasubramanian@ww.uni-erlangen.de

INTRODUCTION

Driven by increasing demand, new strategies for bone tissue engineering are fast developing. Electroflocking is a well-known technique in the textile industry. Walther et al¹ reported the application of flocking as a suitable technology for fabrication of scaffolds for cell culture and tissue engineering (TE). This method offers the possibility to produce scaffolds with fibrous morphology and anisotropic properties. In this study, we report, for the first time, the combination of polymer replication method and flock technology to produce 45S5 Bioglass® scaffolds with a fibrous surface morphology suitable for bone TE. After *in vitro* bioactivity study in simulated body fluid (SBF), complete mineralization of the flocked polyamide fibers in contact with the Bioglass® scaffold was observed.

EXPERIMENTAL METHODS

Polymer replication method: 45S5 Bioglass® scaffolds were produced as described by Chen et al².

Electroflocking: In this technique, short fibers are applied under an electrical field to a substrate covered with an adhesive. Figure 1 shows the experimental set-up for the flocking technique¹.

Figure 1: Schematic diagram of the electroflocking process

For our experiment, the Bioglass® scaffold was used as the substrate, gelatin is the adhesive and polyamide (PA) fibers of the length 0.5 mm and diameter 15 µm were used. Gelatin was dissolved in de-ionised water and applied on the top surface of the Bioglass® scaffolds. Short fibers were flocked over the gelatin layer to obtain a fibrous morphology on the surface of the Bioglass® scaffolds. Different flocking time periods (10s, 30s and 60s) were considered. The scaffolds were then taken for further characterisation and *in vitro* bioactivity studies.

RESULTS AND DISCUSSION

Three-dimensional porous scaffolds based on Bioglass® were produced from the polymer replica technique². The scaffolds were analysed by scanning electron microscopy (SEM). Other characterisation techniques were also used to investigate the scaffolds (not shown here). Figure 2(a) shows a SEM image of the Bioglass® scaffold after flocking with PA fibers for 60s. From Figure 2(b), the adhesion of the PA fibers on the gelatin layer can be seen.

Figure 2: SEM micrographs of (a) and (b) PA fibers over the gelatin adhesive layer on Bioglass® scaffold after electroflocking for 60s

The Bioglass® scaffolds after flocking were immersed in SBF for a period of 28 days. Figure 3(a) and 3(b) show the formation of Hydroxyapatite (HA) on the Bioglass® as well as polyamide fibers after 28 days in SBF.

Figure 3: SEM micrographs of HA growth on (a) PA fibers (b) PA fibers and Bioglass® scaffold

Flocking after 10s produced surfaces with fibers of low packing density. Increasing the flocking time increased the packing density of fibers. Higher density of fibers on the surface prevented toppling of fibers as there is only limited space available. It was observed that after the SBF study, the orientation of the fibers had changed and not all the fibers were perpendicular to the substrate. Interestingly, the polyamide fibers were also completely covered with HA crystals. By choosing an appropriate flock density (i.e pore size), scaffolds with suitable properties for cell adhesion and growth can be created.

CONCLUSION

Novel scaffolds for TE combining the foam replica technique and electroflocking of PA fibers were fabricated. *In vitro* bioactivity studies indicated mineralization of both the Bioglass® scaffold and polyamide fibers. In the future, other types of fibers with encapsulated or surface functionalized proteins or biomolecules can be flocked over bioactive glass scaffolds for developing functional scaffolds for drug delivery applications for bone regeneration.

Translation of science to the clinic: Where preclinical research fits in the model

R. Geoff Richards

AO Research Institute Davos, AO Foundation, Clavadelerstrasse 8, 7270 Davos, Switzerland
geoff.richards@aofoundation.org

The AO Research Institute Davos (ARI) within the AO Foundation has many of the conditions desired to have success in translation of scientific results into surgical procedures, marketable substances or prototype concepts for medical devices¹. The ARI is a multidisciplinary highly motivated and focused research team in one location with a world-wide network of academic, clinical and industrial partners within specialised fields of trauma. All projects are initiated from specific clinical problems facing the trauma surgeon and funding is all project based (not department based) using full cost financial controlling. The ARI has accreditation of R&D processes, facility and animal care (ISO and AAALAC). Within the AO Foundation the ARI has access to the well respected and largest world-wide trauma surgeon network for clinical guidance. This network brings both international and regional based clinical problem experience and knowledge to help with analysis of clinical problems and development of research solutions. Within the AO Foundation also exists a central clinical trials team which works with the clinical network members. It can host multicenter trials and also can give accreditation to hospitals to participate. The AO Foundation also provides the ARI access to an experienced medical guided approval body for the devices and techniques with independent surgeons with regional and specialty representation. The AO Education Institute has a clinical education team which with its theme based on both faculty and curriculum development processes for the attendees and runs over 400 courses a year world-wide for surgeons and operating room personnel. Naturally this is the place to show new technology (techniques, devices, substances) which are either in development or already available clinically.

As the research part of the Foundation, bringing academic credibility to new substances, devices and techniques, one dilemma in would be whether to hold back publishing in order to submit a patent. This can delay academic recognition, yet helps to make the idea tradable after filing the patent and if given gives a strong legally enforceable protection of the invention (can take 5 or more years). First of all one should check that the idea is really novel through a patent search and knowing the literature and secondly if novel, it must also be inventive. Terminology here is critical as are the claims which must be solutions as opposed to problems.

Despite the great set up to nurture, approve and expose translation within the AO Foundation key areas of the translation cycle are missing in the more biological ideas. As the ARI has moved in the last 20 years slowly away from pure biomechanics to biology and tissue engineering and regenerative medicine it is evident the industrialisation steps are much more difficult. In the early 90's ARI performed early work with

biodegradable polymers for bone fillers (with and without cellular material), membranes for bone defects along with biological manipulation of surrounding tissues, such as periosteum transport and fillers between the periosteum and bone to encourage more bone repair. Unfortunately much of this work was never really translated to the clinics at that time and such areas have been "rediscovered" with newer materials and marketed as new ground breaking work.

There is an increasing clinical demand for the targeted and controlled delivery of active molecules (or even cells) to specific parts of the body which requires good well characterised biomaterial delivery platforms e.g. for localised delivery of antibiotics to infection sites or release of stimulants for local tissue regeneration. The biomaterials ideally should be biocompatible, biodegradable and allow temporal release of the active substances. It also makes things easier (and much cheaper) if the biomaterial platform's components are already used for other areas in the clinics. The translation of such a material to the clinics involves many more steps than is involved for a device made of steel or titanium. Should these missing areas of development for translation be brought into the translation circle internally by hiring specialists for technology transfer and licencing to industry, certification (e.g. CE), regulatory issues, GLP and GLM for tissue engineering or should these areas be outsourced to groups who specialise in these areas on a daily basis? This is difficult to answer.

This presentation will mention the generic development process and through examples show some of the pitfalls we have encountered in the last few years at the technology transfer stage. If you want industry to consider your idea you must have several patents covering the areas of interest and the patents must have passed the pre-examination stage. To make sure they do not buy your idea and shelve it, once you have your patent, which is also a commercial strategy, you must make an exploitation contract with financial penalties for inactivity and possible full loss of partnership (again with financial penalty) if no activity happens within a certain period.

There are thousands of great ideas, but to turn just one of these into a successful device, substance or procedure in surgery requires much more than a great idea. A well thought out plan with appropriate searches focussed initially on just one clinical problem is essential to get to an evidence based proof of concept to be able to present and licence or sell to industry.

Innovation and Product Development in a Changing Regulatory and Socio-economical Environment

Andrea Montali¹

¹DePuy Synthes Biomaterials R&D, Oberdorf, Switzerland
montali.andrea@synthes.com

INTRODUCTION

Innovation and product development in orthopaedic medical device industry have largely been technology driven during the last decades. Advancements have been rapid and significant. Today's solutions have reached high standards and nowadays an individual suffering from a bone fracture in highly developed countries can count on receiving a state of the art treatment and regaining full mobility and quality of life in the vast majority of cases.

While in the past, technological advancements and new scientific insights have been driving innovation, today's product development occurs in a more complex environment, with multiple stakeholders involved. Each of these stakeholders can have different and sometimes conflicting requirements and expectations. While technological innovation may still be the driving force behind new product developments, in many cases it is not a sufficient justification.

FRAMEWORK OF PRODUCT DEVELOPMENT

Product development is nowadays always subject to the indirect or direct influence of three independent conditions:

- 1) Success rates of state of the art treatments are very high and any improvement is difficult to prove.
- 2) Regulatory authorities request proof of any improvement in performance.
- 3) The entire market is subject to significant cost and price pressure.

These frame conditions make any new product development and the implementation of any technological innovation an endeavour subject to continuous, in depth scrutiny questioning technological, regulatory and financial feasibility.

SHIFT OF PARADIGMS IN INNOVATION

To a certain extent these external factors are contradictory to the typical structure of a traditional R&D project, where an innovative technology is brought to maturity, made into a product and brought to the market.

Such a project can involve extensive pre-clinical testing to demonstrate safety and effectiveness; furthermore, in many cases significant investments in generating clinical proof of efficacy and safety may be required. This stands in stark contrast to the above stated requirements of profitability, as timelines and costs are significant.

Industry faces the need to expand and redefine its concept of innovation and product development in order

to offer added value to its customers and their patients, while still maintaining reasonable development timelines and project profitability.

This calls for taking a step back from the hitherto common definition of "product", which focuses on an implant and the related instruments and surgical technique necessary for implantation.

While optimal patient treatment with best possible outcomes remains the centre of the treatment around which everything else revolves, services addressing other aspects of the treatment continuum can bring benefits to different stakeholders, which in the end may justify a development even if minor technological improvements are not the driving force.

These can be services around simplifying logistics and warehousing in clinics, or support in pre-operative planning and post-operative patient support, which can lead to earlier release from the clinic and return to work. An industrial partner with a deep understanding of the processes needed to offer a successful and efficient treatment of patients, from the moment of injury to full reintegration into daily life, can offer new benefits and innovation in fields that were so far not considered to be in the scope of an orthopaedic company's development activities and product offerings.

CONCLUSION

In the coming years, new product developments in the field of orthopaedics will face more and more scrutiny with regards to the benefits they bring to patients and their overall profitability. More complex products involving bioengineered components, which typically require more extensive pre-clinical and clinical testing to demonstrate safety and efficacy, will face even more significant challenges than others.

However, treatments based on bioengineering technologies bear the potential to fully change the treatment of certain diseases and injuries, thereby offering real benefit, not just to the patient, but also to other stakeholders such as insurance companies or hospital administrations.

Assuring that a new product development is embedded in a more holistic consideration and takes into account all aspects of treatment, also those occurring outside the operating theatre, will open new possibilities to demonstrate efficacy and profitability. This is of utmost importance and will be the decisive factor determining the fate of a project and product idea.

Development of dedicated tools for personalization of medical devices

Lara Vigneron¹, Daniel Daryaie², Sebastian De Boodt¹, Lars Neumann^{1*}

¹Biomedical Engineering Department, Materialise NV, Belgium, Lars.Neumann@materialise.be

²Biomedical Engineering Department, Materialise NV, UK

INTRODUCTION

Human beings are diverse in their physical makeup and there is a growing trend towards personalization of medical care. In the surgical field, it is translated by an increasing use of personalized or patient-specific anatomical models, surgical instruments and implants. Next and related to this trend of personalization, there is a push from public actors (government, regulatory entities, etc.) for evidence-based medicine, which leads to more thorough population analyses for improving design and evaluating surgical outcomes. In this paper, we describe the use of 3D medical image information of individual patients as well as selected patient populations, combined with computer aided engineering (CAE) tools and processes, in the rapid product development of personalized medical devices and the analysis of surgical outcomes.

EXPERIMENTAL METHODS

Medical imaging systems, like CT or MR scanners, typically generate stacks of gray scale images. To take full advantage of the 3D- and density information that is included in these image stacks, medical image and design software Mimics[®] Innovation Suite (Materialise NV, Leuven, Belgium) is used. It generates 3D models of the tissues of interest thanks to segmentation tools and advanced interpolation algorithms, allowing the user to create accurate 3D models. Personalized parts are then designed thanks to dedicated Computer Aided Design (CAD)-tools. Nowadays, most personalized medical devices are produced using 3D printing techniques, as they allow maximum flexibility to personalize production for each part to be built. 3D printing production requires dedicated tools and data format that are also included in the software.

Designs of standard implants are increasingly based on advanced population analyses that provide a better understanding and differentiation of the targeted population, including for example different ethnicities such as Caucasian or Asian, etc. or of healthy populations and populations showing specific disorders, e.g. osteoarthritis. We have thus developed dedicated software tools to build statistical shape models that allow the generation of virtual models representative of the population, i.e. average model and models presenting the main shape of variations. Conception and virtual testing of new designs can thus be performed using models that cover the target population in a better and more systematic way than using arbitrarily chosen datasets¹.

In order to evaluate surgical outcome, planning and postoperative results should be compared. The most accurate method is to acquire a new 3D image of the

patient after the surgery that allows evaluating the exact position of the implant relative to the anatomy². However, this 3D postoperative image is often not included in the standard clinical protocol and it increases the level of radiation dose that the patient receives, which is to be avoided. We have thus developed a software tool for postoperative analysis based on a pair of X-ray images only, which reaches a level of accuracy that is comparable with the results obtained with a 3D postoperative image.

RESULTS AND DISCUSSION

Some of our results are presented below. The first figure presents (from left to right) a 3D model created from CT DICOM images and used to plan surgical cuts. An implant was then designed and produced that fits exactly onto the patient's bone anatomy. FEA analysis was performed to validate the stability of the implant under different loads.³

The second figure presents the method to perform a postoperative analysis using a pair of X-rays. These are used to define the relative position of bone and implant in 3D space. This position is subsequently compared to 3D surgical planning.

CONCLUSION

We have developed powerful tools to conduct the whole workflow going from design of patient-specific medical devices and planning of surgery to postoperative analysis.

INTRODUCTION

Advancements in tissue engineering and polymer chemistry have enabled development of scaffold-free substitutes; a technology termed as Tissue Engineering by Self-Assembly¹. Despite efficacious *in vitro* and *in vivo* results, very few products have been commercialized, primarily due to prolonged culture time^{2,3}. It has been demonstrated that macromolecular crowding (MMC) enhances deposition of extracellular matrix (ECM)^{4,5,6}. Here, we assessed the potential of combining MMC technology with a Tissue Engineering by Self-Assembly approach.

EXPERIMENTAL METHODS

Human fibroblasts, tenocytes and osteoblasts were cultured under various MMC conditions [dextran sulphate (DxS); Ficoll™ & carrageenan (CR)] in a range of fetal bovine serum (FBS) and human serum (HS) concentrations (0.0-10%). ECM deposition was analysed by SDS-PAGE, immunocytochemistry (ICC), zymography, atomic force microscopy (AFM), scanning electron microscopy (SEM) and mass-spectrometry (MS). MMC molecules were characterized by dynamic light scattering (DLS) and nanoparticle tracking analysis (NTA). The influence of crowders on cell morphology, cell viability and metabolic activity were evaluated using phase-contrast microscopy, Live/Dead® and AlamarBlue® assays respectively. NIPAM based thermo-responsive polymers were developed to facilitate detachment of ECM-rich cell-sheets.

RESULTS AND DISCUSSION

Densitometry of SDS-PAGE demonstrated that MMC significantly increase type-I collagen deposition ($p < 0.0001$) at all tested serum concentrations (maximum deposition was in 2 days & 0.5% FBS or HS). (figure-1). High matrix metalloproteinase-2 (MMP-2) content of FBS/HS was revealed by gelatin zymography (Figure 2), that attributed reduction in collagen content as a function of increased serum concentration.

ICC, AFM and SEM further confirmed enhanced deposition of fibrillar ECM in presence of MMC (figure-3, a-h).

DLS and NTA demonstrated that CR has highest polydispersity among all tested crowders. Phase-contrast microscopy, Live/Dead® and AlamarBlue® assays confirmed that cellular morphology, viability and metabolic activity respectively were not affected by MMC. Thermo-responsive coating with 65% NIPAM: 35% N-tert-butylacrylamide facilitated detachment of ECM rich cell-sheet from culture (figure-4, a-d).

Complementary ICC for MS validation confirmed the enhanced deposition of collagens (III, IV, V, VI) and other ECM molecules (laminin, fibronectin, hyaluronic acid, decorin, lysyl oxidase), without changing collagen-VII, elastin, fibrillin-1, transglutaminase-2, α -smooth muscle actin, epithelial keratin, tubulin, chondroitin sulphate, keratin sulphate, heparin sulphate, aggrecan, biglycan, CD248 and IL-10.

CONCLUSION

Modulation of *in vitro* microenvironment with polydispersed macromolecular crowders enhances ECM deposition even under low serum supplementation and facilitates production of intact ECM rich cell-sheets when combined with novel thermo-responsive polymer coating.

Collagen Plasma Treatment of Poly-(ether-ether)-ketone for Improved Cell Attachment

Jessica S Hayes^{1*}, Declan M Devine, Mary Murphy¹

¹Orthobiologics, Regenerative Medicine Institute, NUI Galway IE

²Material Research Institute, Athlone Institute of Technology, IE, *jessica.hayes@nuigalway.ie

INTRODUCTION: Poly-(ether-ether)-ketone (PEEK) has proven successful in the stabilisation of non-load bearing areas of fracture healing¹. Given its desirable Young's modulus, mechanical strength and radiolucency for imaging^{2,3}, PEEK is now studied for more demanding load-bearing orthopaedic applications. A limitation of PEEK is its low surface energy which induces a peri-implant fibrous tissue capsule, thus preventing direct osseointegration⁴. Attempts have been made to 'activate' the surface of PEEK but have had limited success⁵. Our strategy involves the use of low energy plasma to molecularly re-engineer the first few nanometres of PEEK with Collagen to aid attachment. We hypothesise that biofunctionalisation of PEEK will produce a stable modification that improves human mesenchymal stem cell (hMSC) attachment compared to unmodified controls. The overall aim is to use this technology as a method for improving outcomes of osseointegration in orthopaedic applications.

EXPERIMENTAL METHODS

Surface Characterisation: PEEK and plasma treatment were supplied by EnBio Ltd, IE. Surface morphology post-treatment was assessed using Scanning Electron Microscopy (SEM). White light Interferometer was used to assess potential changes in surface roughness as a consequence of plasma treatment. X-ray photoelectron spectroscopy (XPS) was used to assess chemical compositional changes. Contact angle was performed at 0,1, 2, 3, 6 and 12 months to assess ongoing stability at room temperature. XPS was performed at 12 months and compared to time 0 results.

Biological Assessment: hMSC's (n=min 3 donors and min 3 biological replicates per experiment) were seeded at a density of 2×10^4 cells/cm² on 10mm 1) Unmodified PEEK (Unmod PEEK) and 2) Collagen plasma treated PEEK (PEEKCOL). Tissue culture plastic was included to control for donor variability. After 4 and 24hr cell attachment was assessed using Cell Titre Blue as was viability and proliferation up to 10d. Statistical analysis was performed using GraphPad Prism, $p < 0.05$ was deemed significant.

RESULTS AND DISCUSSION: Characterisation of surface morphology suggests that biological modification for the treatment time does not alter surface morphology (Fig1A) or microroughness compared to unmodified controls (Fig1A inset). PEEK was successfully modified with collagen, as indicated by XPS and contact angle. Interestingly, plasma treatment with collagen appears to remain stable for up to 12 months post-treatment (Fig1B). Initial cell attachment is significantly improved on modified surfaces compared to unmodified controls (Fig 1C). Furthermore, cell proliferation and viability are maintained (not shown).

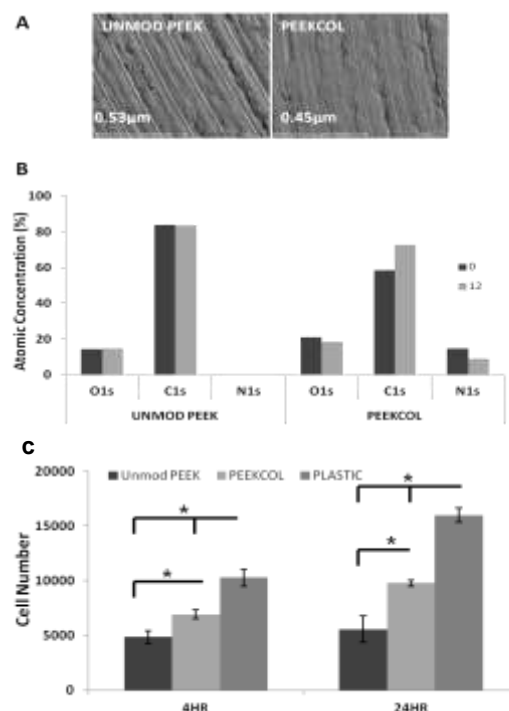

Fig.1.(A) Treatment does not alter surface morphology or roughness (B) XPS at 0 & 12 months indicating stability of modification (C) cell attachment is significantly ($p < 0.001$) improved on PEEKCOL samples compared to controls.

Bioactive PEEK holds great promise for load bearing orthopaedic applications. This approach also offers a commercially cost effective modification compared to current approaches. Given the modification is retained within the surface chemistry; this negates issues relating to internal cohesion rupture or delamination that have been observed for other coating modalities. Additional studies are focusing on the effect of modified PEEK for improving osteospecific differentiation, prior to testing in a relevant preclinical model.

CONCLUSION: Preliminary results suggest that plasma treatment of PEEK provides a clinically applicable method for enhancing cell attachment. A stable surface modification of PEEK can be achieved and in theory is not limited to PEEK or to the factors tested. This method may provide additional avenues to further improve outcomes of osseointegration.

PCL/HA functional gradient scaffold for Osteochondral Tissue Engineering applications

Alessandra Marrella and Silvia Scaglione*

National Research Council (CNR), IEIIT Institute, Italy, silvia.scaglione@ieiit.cnr.it

INTRODUCTION

Joints trauma and disease is one of the most prevalent disorders of the musculoskeletal system, involving structural damage to the articular tissue. It would be a major breakthrough to design and develop novel engineered grafts able to induce a specific cellular response addressed to the long-term in vivo tissue regeneration/integration besides properly interfacing with different host tissues^{1,2}.

We here propose novel morphologically and chemically graded 3D scaffold prototypes mimicking the physiological niche of the articular tissues to achieve continuous transition in both structural and functional tissue properties.

EXPERIMENTAL METHODS

Polycaprolactone (PCL) pellets and Hydroxyapatite (HA) powders were heated together (120°C) and poured into water with vigorous agitation (20.000 rpm) to obtain fibril-like PCL/HA-suspended solution (2/1 w/w ratio). Fibers were dried and re-suspended in water. The solution was centrifuged at different speeds and then freeze-dried; the final PCL/HA scaffold prototypes were mechanically reinforced heating nearby PCL melting temperature (59°, 1h). Morphological structure of scaffolds was observed by a scanning electron microscope (SEM). Functional tests have been also carried out in vitro with and without the use of a custom-made bioreactor able to apply a continuous perfusion and/or dynamic compression stimulation. Progenitor mesenchymal cells were cultured up to 2 weeks within scaffolds; cell survival, adhesion, differentiation and matrix deposition within 3D scaffolds have been evaluated at different time points.

RESULTS AND DISCUSSION

3D highly porous graded scaffolds were successfully realized via a fibril bonding process. The total porosity of prototypes resulted up to 80%±3% for all the scaffolds.

Fig.1: SEM images of the increasing porosity and decreasing gradient of HA (white spot) along the z-axis from left (bottom) to right (top).

Using 3000 rpm centrifuge speed for 5 minutes, SEM analysis confirmed a decreasing chemical gradient (provided by Ha powders) and an increasing pore size gradient along the z-axis (Figure 1). Both total porosity and pore size were statistically different ($p < 0,05$) comparing bottom and top side of the 3D scaffolds. These differences were maintained event introducing the chemical gradient (Figure 2).

Fig.2: Morphological analysis of pore dimensions of graded scaffolds.

Preliminary biological experiments highlighted cells homogeneously colonizing the overall internal structure of graded scaffolds. Perfusing cell culture through the bioreactor increased the cell adhesion efficiency if compared with static culture.

CONCLUSION

This technique allowed realizing 3D functional graded grafts with different porosity ranges and chemical features, finally mimicking the physiological niche of the articular tissue and potentially guide a selective cellular differentiation and tissue regeneration.

These promising results open the possibility to validate in vivo such functionalized scaffolds, and produce novel bioactive replacement grafts for articular joint tissue engineering applications.

Self-assembled Peptide Gels for Intervertebral Disc Tissue Engineering

Simon Wan¹ Alberto Saiani¹ Stephen Richardson² Julie Gough¹

¹School of Materials, the University of Manchester, UK

²Faculty of Medical & Life Sciences, the University of Manchester, UK

simon.wan@postgrad.manchester.ac.uk

INTRODUCTION

Low back pain (LBP) has reached epidemic proportions in the Western world and has been estimated to cost the UK economy £12 billion per annum¹. LBP aetiology is multi-factorial however intervertebral disc (IVD) degeneration is strongly associated with the condition². LBP prevalence is increasing whilst current treatments are ineffective, therefore a new strategy is required for LBP management. Cell-based therapies are regarded to hold particular promise as they have the potential to retard and even reverse IVD degeneration.

In this project, we investigated a self-assembling peptide hydrogel for its potential use as a cell-delivery tool and scaffold in nucleus pulposus (NP) tissue engineering. The hydrogel was chosen due to its biocompatibility, its injectability and the ease at which it can be modified to manipulate properties. The 3D culture of bovine NP cells (bNPCs) was first carried out as a model system then human bone marrow derived mesenchymal stem cells (h-BMMSCs) were investigated, as they have been identified as a promising cell source for NP tissue engineering, mainly due to their ability to differentiate into NP-like cells³.

EXPERIMENTAL METHODS

Cells were encapsulated in 30 mg ml⁻¹ gels. Atomic force microscopy (AFM) and rheology were used to characterise the gels. Bovine NPC and h-BMMSC morphology and viability was determined using fluorescence microscopy and LIVE/DEAD assay. Lactate dehydrogenase (LDH) assay was used to record changes in cell population. Dimethylmethylene blue (DMMB) assay was used to quantify glycosaminoglycan (GAG) production after bNPC encapsulation in the gel. Immunocytochemistry (ICC) was used to stain for extracellular matrix (ECM) components, specifically collagen, produced by bNPCs.

RESULTS AND DISCUSSION

AFM showed that the gel consisted of a dense nanofibrous network. Larger nanofibre assemblies were of similar size to type II collagen fibrils found in the native NP⁴. Rheology demonstrated that gels could be produced that were of comparable strength to the native NP which is crucial due to the mechanical roles of the tissue. Fluorescence microscopy showed that bNPC viability remained high throughout cell culture. Micrographs showed that cells displayed their characteristic rounded morphology when encapsulated. LDH assay showed no significant changes in cell population. Bovine NP cells were shown to produce ECM components associated with the NP. ICC demonstrated that type II collagen, which has a

mechanical role in the tissue, was being expressed inter- and extracellularly. Type I collagen wasn't produced by bNPCs; production of type I collagen is associated with IVD degeneration and NPC de-differentiation (**fig.1**). Bovine NPCs were shown to produce sulphated-GAGs with the amount produced per cell increasing with time point.

Figure 1. Collagen staining of 1×10^5 bNPCs encapsulated in peptide gel on day 7. [A] Negative staining for type I collagen [B] Positive staining for type II collagen. Collagen is stained red, F-actin is stained green and cell nuclei are stained blue.

Fluorescence microscopy showed that h-BMMSC viability was high for the duration of culture. LDH assay supported these findings with cell population remaining stable.

CONCLUSION

Results support the hypothesis that the peptide gel could act as an effective cell delivery tool and scaffold for NP tissue engineering. It is probable that the nanofibrous architecture of the gel biomimics the native NP tissue which is why bNPCs maintained a rounded morphology and produced the appropriate ECM components. Preliminary h-BMMSC results are promising but more investigation is required.

Utilizing Multifunctional Alginate Scaffolds for the Regeneration of Skeletal Muscle Defects in a Rat Crush Trauma Model

Taimoor Qazi^{1*}, Matthias Pumberger², Tobias Winkler², Sven Geißler¹, David Mooney³, Georg Duda¹

¹Julius Wolff Institute, Charité - Universitätsmedizin Berlin, Germany, taimoor.qazi@charite.de

²Center for Musculoskeletal Surgery, Charité-Universitätsmedizin, Berlin, Germany

³School of Engineering and Applied Sciences, Harvard University, USA

INTRODUCTION

Severe trauma to the skeletal muscle can not only result in fibrous scar tissue formation, but can also lead to loss in muscle functionality. The existence of such functional deficits due to insufficient regeneration is a serious issue in orthopaedic and trauma surgery. The potential of mesenchymal stem cells (MSCs) in regeneration of skeletal muscle following open crush trauma was shown previously by our group¹. Sustained delivery of pro-myogenic (IGF-1) and pro-angiogenic (VEGF₁₆₅) growth factors from an alginate scaffold has also been shown to result in functional improvement of skeletal muscle². We hypothesized that a combination of growth factors and MSCs delivered in a porous alginate scaffold would not only shield the cells from a harsh immune environment, but also act as a repository for the MSCs to exert their influence on muscle repair.

EXPERIMENTAL METHODS

Low and high molecular weight ultrapure alginates were oxidized and coupled with G₄RGDSP peptide sequences. The alginates were mixed in the ratio 1:1 and gelled using a calcium sulphate slurry. The growth factors (IGF-1 and VEGF₁₆₅) were mixed with the alginate at a concentration of 1 µg/µL before gelation. Samples of the hydrogel were stored at -80° C before being lyophilized to create a porous structure. MSCs were derived from bone marrow biopsies of female Sprague Dawley rats. Cell suspensions consisting of 1 million MSCs were seeded per scaffold. Preliminary assessment of scaffold structure, cell-matrix interactions, and growth factor release kinetics was carried out in vitro. The in vivo study design consisted of four test groups: (1) Blank Alginate, (2) Alginate + MSCs, (3) Alginate + Growth factors, (4) Alginate + MSCs + Growth factors. In each case, the transplantation was carried out following an open crush trauma to the soleus muscle. 1 and 4 weeks after transplantation, the rats were anaesthetised and muscle contraction forces (fast twitch and tetanic) were measured. The forces were normalized to those generated by the healthy leg. The soleus muscles were then explanted for histological evaluation.

RESULTS AND DISCUSSION

In vitro experiments showed a sustained release of growth factors (table 1) and good cell-matrix interactions (cell attachment and morphology, cell viability). Figure 1 depicts a scanning electron micrograph of the porous scaffold. No significant difference in muscle contraction forces could be observed in any group after 1 week of transplantation.

However, after 4 weeks, clear enhancements of fast twitch forces were seen for the groups Alginate + MSCs (74 ± 12 %), and Alginate + MSCs + Growth factors (83 ± 10 %), relative to the control (61 ± 9 %).

Table 1: Growth factor release kinetics from alginate scaffolds measured over a period of 28 days.

Day	IGF release (%)	VEGF release (%)
1	1.40 ± 0.1	9.0 ± 5.1
7	22.94 ± 8.5	78.90 ± 1.1
14	38.88 ± 2.4	83.17 ± 0.2
21	52.38 ± 3.3	85.44 ± 0.1
28	59.56 ± 9.1	87.59 ± 0

Figure 1: The porous structure of the alginate scaffolds was confirmed with Scanning electron microscopy (SEM).

Figure 2: Fast-twitch muscle contraction forces of the control group (Alginate) and other study groups, 1 and 4 weeks after transplantation. * represents statistical significance (p < 0.05) compared to the control group.

CONCLUSION

These results show for the first time that transplantation of alginate scaffolds loaded with MSCs results in significant increase in muscle strength compared to blank scaffold transplantation. The effect is further enhanced upon incorporation of the growth factors IGF-1 and VEGF₁₆₅, indicating the utility of employing a combined approach for muscle regeneration.

³Büchi Labortechnik AG, Switzerland

INTRODUCTION

The progress of medical therapies, which rely on the transplantation of microencapsulated cells, depends on the quality of the encapsulating material. Such material has to be biocompatible, its physical characteristics have to be adjustable, and the microencapsulation process must be simple and not harm the cells.

We produced biocompatible one- and two-component hydrogel microspheres (MS) by combining ionotropic gelation of sodium alginate (Na-alg) using calcium ions with covalent crosslinking of poly(ethylene glycol) derivatives (PEG)¹⁻⁴. Multi-arm PEG was either mixed with Na-alg^{1,3,4} or heterobifunctional PEG was grafted onto the carboxyl groups of Na-alg².

Differently to our previous materials, we present now hydrogels prepared by grafting either PEG onto the hydroxyl groups or cystamine dihydrochloride onto the carboxyl groups of Na-alg, and demonstrate their suitability for cell microencapsulation.

EXPERIMENTAL METHODS

Fig. 1. Functionalization of Na-alg by grafting heterobifunctional PEG onto the hydroxyl groups (Na-alg-PEG).

Fig. 2. Functionalization of Na-alg by grafting cystamine dihydrochloride onto the carboxyl groups (Na-alg-cys).

¹H-NMR, ¹³C-NMR and FTIR were used for polymer analyses. The polymer solutions were characterized by their viscosity and osmolality. An Encapsulator B-395 Pro was used to produce MS. The MS were characterized in terms of size/swelling (microscopy), mechanical resistance to compression (texture analyser TA-XT2), and permeability (ingress diffusion). Human

foreskin fibroblasts (EDX cells) and islets were used for *in vitro* and *in vivo* studies. Encapsulated rat and human islets have been transplanted into mice.

RESULTS AND DISCUSSION

The functionalized Na-alg-PEG and Na-alg-cys allow for cell microencapsulation by a one-step process. Upon extrusion into the gelation bath, the fast ionotropic gelation with calcium ions ensures the spherical shape of the hydrogel while the simultaneously but slowly occurring covalent crosslinking reinforces the hydrogel mechanically and adjusts its permeability. Both the mechanical properties and the permeability of the MS can be adjusted in a range considered favorably for cells by varying the degree of grafting and the polymer solution concentration.

Long-term survival and function of EDX cells *in vitro* confirmed the biocompatibility and durability of the two types of MS. Fig. 3 shows EDX cells in Na-alg-PEG.

Fig. 3. Left to right: Homogeneous distribution of EDX cells in Na-alg-PEG; single MS; FDA staining; PI staining; MS: 600 $\mu\text{m} \pm 10\%$.

Static incubation tests confirmed survival and function of microencapsulated rat and human islets. Upon xenotransplantation into diabetic mice, normoglycemia was achieved in the period of months. The long-term *in vivo* experiments continue.

CONCLUSION

Two novel types of alginate-based MS have been engineered. Their physical and biological properties as well as the production process are favourable for cell microencapsulation. *In vitro* and *in vivo* studies confirmed the suitability for the development of cell therapies.

INTRODUCTION

Bioactive glasses and glass-ceramics show direct bonding to living bone, i.e. osteoconduction, when implanted in bony defect. Their osteoconduction would be accomplished through formation of biologically active hydroxyapatite layer by chemical reaction of their surfaces with body fluid. This layer has similarity in its composition and crystalline characteristics to inorganic phase in natural bone, and is called bone-like apatite. Potential of the bone-like apatite formation can be evaluated *in vitro* using a simulated body fluid (SBF) reported by Kokubo and his colleagues¹. After the report on compositional dependence of the apatite formation on CaO-SiO₂-P₂O₅ glasses in SBF, CaO-SiO₂ binary glass has been regarded as important composition for the bone-like apatite formation. The CaO-SiO₂ glass show the bone-like apatite formation due to dissolution of Ca²⁺ to surrounding fluid, as well as heterogeneous apatite nucleation induced by Si-OH groups in silica hydrogel formed on the glass surface². However drawback of the bioactive glass is lower fracture toughness and higher Young's modulus than natural bone. This limits their applications to low loaded conditions. Organic-inorganic hybrids composed of organic polymers and inorganic species providing Si-OH groups and Ca²⁺ are expected to solve the above problems. In the present topic, design of organic-inorganic hybrids able to form the bone-like apatite is reviewed for development of novel osteoconductive materials.

EXPERIMENTAL METHODS

Sol-gel processing is a typical method for preparation of organic-inorganic hybrids through organic modification of calcium silicate. Polydimethylsiloxane (PDMS)-silicate hybrids with incorporation of calcium nitrate (Ca(NO₃)₂) were prepared by sol-gel processing³. Organically modified silicates with reduced amounts of siloxane networks were prepared from 2-hydroxyethyl methacrylate and methacryloxypropyltrimethoxysilane (HEMA-MPS) with addition of calcium chloride (CaCl₂)⁴. Polysaccharide-based hybrids were also prepared by appropriate modification with alkoxysilane and calcium salts. Alginate was chemically modified with aminopropyltriethoxysilane (APTES), followed by treatment with CaCl₂⁵. Starch-based hybrids modified with glycidoxypropyltrimethoxysilane (GPS) were prepared in different concentrations of GPS with incorporation of CaCl₂⁶.

SBF was prepared according to Kokubo's recipe¹. Apatite formation on the specimens was examined generally by X-ray diffraction, Fourier transform infrared spectroscopy and scanning electron microscopic observation. In some cases, changes in pH,

calcium and phosphorus concentrations of SBF were measured.

RESULTS AND DISCUSSION

Synthesis of organic-inorganic hybrid of PDMS-silicate with Ca(NO₃)₂ incorporation would give structure consisting of silica blocks with PDMS chains. Ca(NO₃)₂ incorporation may lead to the bone-like apatite formation in SBF³. HEMA-MPS hybrids showed improved flexibility that is expected by reduced amount of siloxane networks. Soft material could be obtained at starting composition of HEMA:MPS:CaCl₂ = 0.9:0.1:0.1 in molar ratio, and it deposited the bone-like apatite in SBF within 7 days⁴. Mechanical properties of the hybrids can be also well controlled by kind of the catalyst in sol-gel processing⁷.

Alginate modified with APTES and subsequently treated with CaCl₂ showed the bone-like apatite formation in SBF⁵. Starch-GPS hybrids modified with CaCl₂ also showed the bone-like apatite formation in SBF. The starch-based hybrids varied their mechanical characteristics by the amounts of GPS⁶. Thus modification of polysaccharide would facilitate development of osteoconductive hybrids with different biodegradation rate and mechanical properties.

CONCLUSION

Various types of organic-inorganic hybrids have been developed from the fundamental understandings on surface reaction of bioactive CaO-SiO₂ glass in SBF. The design of the osteoconductive materials may produce novel bioactive materials for bone repairing with various functions.

INTRODUCTION

Due to their breathability, specific mechanical properties, i.e. high flexural and fatigue strength relative to their weight ratio and biocompatibility, activated carbon clothes (ACC) have previously been considered for hard and soft tissue implanting. However, their poor biological activity restricts their extensive use in medical applications and therefore needs to be enhanced^{1,2,3}. Thanks to their excellent biocompatibility, osteoconductivity and bioactivity, calcium phosphate (CaP) ceramics, especially hydroxyapatites (HA), have received much attention in the biomedical materials field and have been clinically applied in orthopaedics³. So, carbon fiber-reinforced HA composites, combining the highly biocompatible CaP matrix with the properties of carbon fiber, are promising bioceramic material, which could be particularly useful in the reconstruction of bone defects³.

EXPERIMENTAL METHODS

To get bioactive hybrid materials, CaP coatings are deposited on activated carbon scaffolds by sono-electrodeposition process. A mixture of $\text{Ca}(\text{NO}_3)_2$, $4\text{H}_2\text{O}$ and $\text{NH}_4\text{H}_2\text{PO}_4$ is used as an electrolyte. A three electrode system connected with a potentiostat-galvanostat is used to apply a cathodic polarization at the carbon electrode. The influence of electrochemical parameters is connected to the quantity, microtexture, structure and chemical composition of CaP phases. The materials biocompatibility was determined by culturing human osteoblast-cells (HOST) in contact with CaP/ACC hybrid materials.

RESULTS AND DISCUSSION

Data show that polarization duration influences the deposit thickness: from 500 nm to 5 μm . The mass uptake tends to a limit corresponding to the decrease of nucleation sites. The current density influences the CaP deposit quantity, morphology and chemical composition. Indeed, at low regime, the quantity of deposit is proportional to the applied current density. During CaP deposit, two phenomena occur due to water electrolysis: H_2 release at working electrode surface leads to a more or less homogeneous coating and the electrolyte pH decrease along polarization leads to CaP re-dissolution. SEM, TEM and FTIR characterizations show that the coating consists in a plate-like carbonated octacalcium phosphate for low current densities and needle-like carbonated calcium deficient HA (cdHA) for high current densities. ^1H and ^{31}P NMR MAS of

deposits confirm the presence of carbonated cdHA and underline the presence of minority disordered CaP phases.

In order to improve the coating adhesion, the ACC surface has been functionalized by sono-electrochemistry. Two paths are studied: on the one hand, ACC is oxidized by application of anodic current in Na_2SO_4 aqueous electrolyte. On the other hand, phosphates are grafted on ACC surface by electrochemical oxidation in phosphoric acid aqueous media. Mechanical tests are in progress to assess the adhesion properties between cloth and deposit. Concerning biological experiments, results have shown evidence of biocompatibility of hybrid materials and activity that has stimulated the HOST growth (Fig. 1).

Figure 1: SEM images of human osteoblasts cultured for 7 days in the presence of CaP/ACC hybrid material obtained at low current density.

CONCLUSION

The sono-electrodeposition process consists in a co-precipitation of calcium and phosphate ions with hydroxides ions provided by water electrolysis. It is an efficient method to obtain a controlled thickness, morphology (platelets or needles) and chemical composition of CaP deposits. Preliminary *in vitro* studies of HOST interaction with CaP/ACC material show a good biocompatibility whatever CaP morphologies.

INTRODUCTION

Titanium (Ti) metal and its alloy are widely used as orthopedic and dental implants because of their good biocompatibility and high mechanical strength. However, they do not bond to living bone. The present authors early showed that Ti metal and its alloys bond to living bone through an apatite layer formed on their surfaces in a living body, when a Ca-deficient calcium titanate layer was produced on the metals by NaOH, CaCl₂, heat and water treatments (Ca treatment) [1]. Recently, it was found that strontium (Sr) ions can be incorporated into the surface of Ti metal additionally to Ca ions by modifying the Ca treatment. Sr ion has been attempted to be used in bone healing therapy due to its effects of increasing new bone formation while reducing bone resorption. It is expected that the treated metal could bond to the bone in a shorter period of time because it releases Sr ions and form apatite on its surface.

In the present study, Sr ion incorporation was attempted on the surfaces of Ti alloys such as Ti-6Al-4V and Ti-15Zr-4Nb-4Ta by the modified Ca treatment. Apatite formation on the surface of the resultant product in a simulated body fluid (SBF) and release of Sr ions in a phosphate-buffered solution (PBS) were discussed in terms of the surface structure.

EXPERIMENTAL METHODS

Ti-6Al-4V and Ti-15Zr-4Nb-4Ta alloys with the size of 10 × 10 × 1 mm³ were soaked in 5 M NaOH aqueous solution at 60 °C for 24 h, then subsequently in a mixed solution of 50 mM CaCl₂ and 50 mM SrCl₂ at 40 °C for 24 h. They were heated at 600 or 700 °C for 1 h, and then soaked in 1M SrCl₂ solution at 80 °C for 24 h. The samples were washed with flowed ultra-pure water for 30 sec after each solution treatment.

Surfaces of the samples were examined by a field emission scanning electron microscope (FE-SEM) equipped with energy dispersive X-ray analyzer (EDX), thin-film X-ray diffractometer (TF-XRD), and laser Raman spectrometer (FT-Raman). Apatite formation on the samples were examined by soaking in SBF with ion concentrations (Na⁺ 142.0, K⁺ 5.0, Ca²⁺ 2.5, Mg²⁺ 1.5, Cl⁻ 147.8, HCO₃⁻ 4.2, HPO₄²⁻ 1.0, and SO₄²⁻ 0.5 mM) nearly equal to those of human blood plasma at 36.5 °C [2] for 3 days. The samples subjected to the chemical and heat treatments were soaked in 2 ml of PBS at 36.5 °C. After soaked in PBS for various periods up to 7 days, Ca and Sr ion concentrations in PBS were measured by inductively coupled plasma emission spectroscopy (ICP).

RESULTS AND DISCUSSION

FE-SEM observation showed that nano-scaled network structures were produced on both the surfaces of Ti-

6Al-4V and Ti-15Zr-4Nb-4Ta alloys by the chemical and heat treatments. EDX analysis revealed that former surface contains 1.3 % Sr and 1.8 % Ca, whereas the latter contains 1.1 % Sr and 1.1 % Ca. Thus the formed surface layers were found to be composed of Sr-containing calcium titanate, anatase and rutile by TF-XRD and FT-Raman analysis.

When the treated alloys were soaked in SBF, both of them formed apatite fully on their surfaces within 3 days. When they were soaked in PBS, Ti-6Al-4V gradually released 0.82 ppm of Sr ions in PBS within 7 days, whereas Ti-15Zr-4Nb-4Ta released Sr ions up to 0.38 ppm, as shown in Fig. 1. The lower release of Sr ions from Ti-15Zr-4Nb-4Ta alloy might be due to presence of alloying elements such as Zr, Nb, and Ta in the surface layer, since the Sr content in the surface of the alloy was comparable with that of Ti-6Al-4V alloy.

The released amounts of Sr ions in the present study fall into a range from 0.21 to 21.07 ppm, which is an effective range to increase ALP activity and the expression of a key osteoblast transcription factor gene in hMSCs [3].

It is expected that the treated alloys in the present study could enhance osteoblastic differentiation so as to promote bone formation by releasing Sr ions, and tightly bond to bone through an apatite formed on their surfaces.

Fig.1 Released concentration of Sr ions from Ti alloys subjected chemical and heat treatments, as a square root of soaking time in PBS.

CONCLUSION

Ti-6Al-4V and Ti-15Zr-4Nb-4Ta alloys with Ca-enriched surface layers able to release Sr ions were prepared by the modified Ca treatments.

It is expected that the treated alloys might bond to living bone in a shorter period of time, since they release Sr ions in a living body to promote bone formation, and induces apatite formation on its surface.

INTRODUCTION

Ceramic biomaterials are used for clinical applications as bone grafts to reconstruct bone tissue in defects. Both bone-forming osteoblasts and bone-resorbing osteoclasts play prominent roles in bone formation surrounding the implanted ceramic biomaterials. Osteoclast formation are regulated by osteocytes embedded in bone matrix through the expression of receptor activator of nuclear factor- κ B ligand (RANKL)¹.

We designed the osteocyte-stimulating biomaterials without addition of any growth factors. Osteocytes are most abundant cells in bone, buried in the mineralized bone matrix. Although the osteocytes are used for the evidence for the osteoblast differentiation from the osteoblast progenitors, there are few studies on the interaction between the osteocytes and ceramic biomaterials. In the present study, the interactions of osteocytes with bone marrow cells through the cell-to-cell communications on various types of ceramic biomaterials, were investigated.

EXPERIMENTAL METHODS

Cell culture: Osteocyte-like cells² (MLO-Y4, kindly gifted from Prof. Bonewald) were cultured on the synthesized ceramic biomaterials such as hydroxyapatite (HA) and carbonate apatite (CA), β -tricalcium phosphate (β -TCP), and additionally on bone slices as a control. After 1d culture, bone marrow cells (BMC) isolated from mouse femurs (C57Bl/6J, male, 10-week-old) were added and co-cultured according to the procedure established by Zhao S³.

Staining: The cells adhered to the samples were washed with PBS and fixed with 4% paraformaldehyde. After the PBS washes, the cells were permeabilized with 0.1% Triton X-100 in PBS, stained with rhodamine-phalloidin and Hoechst. The fluorescence signals were observed using a fluorescence microscope.

The fixed cells were also stained for tartrate-resistant acid phosphatase (TRAP) to confirm the differentiation of BMC into osteoclasts.

Observation of resorption pits: After removing the cells, the resorption pits were observed using scanning electron microscope and quantified using laser microscope.

RESULTS AND DISCUSSION

The giant cells with multiple nuclei were formed both on the synthesized CA and bone slices after a co-culture of MLO-Y4 with BMC. These cells were positively stained for TRAP, which indicated that they were

differentiated from BMC into osteoclastic cells without any added differentiation factors. The number of TRAP-positive multinuclear cells was significantly higher on the CA compared to HA among the ceramic biomaterials.

Actin rings, which are specific markers for activated osteoclasts to resorb the substrata, were formed in osteoclasts on the CA and bone slices. The number of actin ring was significantly larger on CA compared to HA among the ceramic biomaterials. As a result, the resorption pits were formed on CA and bone slices.

The possible explanations of the enhanced differentiation and activation of osteoclastic cells on the CA are the cell-to-cell interactions and secretion of differentiation factors from MLO-Y4 cells. Osteoblasts and osteoclast precursor cells are known to interact with each other through the molecules, such as RANKL and macrophage colony-stimulating factor (M-CSF). Therefore, also osteocytes were considered to express the molecules for the differentiation of bone marrow cells into osteoclasts.

CONCLUSION

TRAP-positive and multinuclear cells with actin ring structures were formed by the interaction with osteocyte-like cells and BMC. The formation of mature and activated osteoclasts was enhanced on the CA compared to HA.

INTRODUCTION

Masquelet technique also called induced-membrane procedure was developed to favor bone regeneration using autologous graft and biomaterials in large bone defects. On one hand, due to its osteoconductive properties, hydroxyapatite is a largely used biomaterial to fill bone defects but its tendency to fragment and generate debris with inflammatory potential remains a limitation¹. On the other hand, chitosan is a biocompatible, biodegradable and anti-inflammatory natural polymer². Thus we have combined chitosan and hydroxyapatite to synthesize hybrids and porous 3D scaffolds for bone regeneration³. This work aims to assess their long term biocompatibility *in vivo*.

EXPERIMENTAL METHODS

Scaffolds synthesis and characterization:

Scaffolds characterization included macroscopic and microscopic (Keyence VHX200 numeric microscope) observations, Equilibrium Swelling Ratio (ESR) measurement, EDXS and FTIR analyses and measurement of weight loss overtime.

In vitro biocompatibility study:

Using primary bone cells culture during 7, 14 and 21 days, we evaluated cells viability, proliferation and alkaline phosphatase (ALP) activity. Non parametric stratified permutation test was performed to assess significance of our results (n=6, p<0.05).

In vivo biocompatibility study:

Induced membrane technique was used in a murine model (12 Sprague-Dawley 12 week old male rats) following local animal ethic committee guidelines. After induced membrane generation (6 weeks), rats were treated with hybrid biomaterial or vertebral autologous bone grafts (used as control) for 4 or 12 weeks. Radiographs, echographs and microCT were performed on freshly isolated femurs whereas histological (HPS, Masson's trichrome and May Grünwald Giemsa stainings) studies were performed after decalcification.

RESULTS AND DISCUSSION

Freeze-dried scaffolds were hydrophilic, porous and biodegradable. Moreover detectable amount of β -GP used during hydrogel formation (EDXS and FTIR) was evidenced inside the cross-linked hybrid biomaterial. *In vitro*, cell response to the hybrid scaffolds in terms of cell death, proliferation or ALP activity followed with very few modifications, the measurements of the control patterns. *In vivo*, after four weeks, filling materials were found inside the defect but nor hybrid biomaterial neither autologous grafts allow new bone formation. Nevertheless, collagen neosynthesis could be observed with autologous bone graft. Using hybrid scaffolds, induced membrane appeared thickened more

vascularized and exhibited presence of inflammatory cells that were not present with autologous graft. After 12 weeks, microCT demonstrated that autologous bone was remodeled but failed to create clear union between the edges of the defect whereas osteolytic features seemed to be observed with hybrid scaffold (Figure 1). Histological studies are in progress to precisely assess the later observation, since induced membrane has been recently demonstrated to host many osteoclasts which can explain the strong scaffolds resorption observed³.

Figure 1: MicroCT photographs of critical defect filled with autologous vertebral bone graft (A) or hybrid scaffold (B) 12 weeks after implantation.

CONCLUSION

In this study, we have provided evidence that unexpectedly our hybrid scaffolds seemed not to be suitable for bone regeneration purpose. Future works will include selected biomacromolecules in the scaffolds to enhance osteoconductive and osteoinductive skills as well as immunomodulatory molecules to control peri-implant osteolysis.

INTRODUCTION

Inflammatory response is a natural event following biomaterials implantation. The concept of “fighting inflammation” has been gradually shifting to “modulating inflammation”¹. Our team has previously shown that the incorporation of a pro-inflammatory and pro-healing molecule, fibrinogen (Fg), in chitosan scaffolds is able to modulate the systemic immune response while improve bone regeneration².

In this study we addressed the potential of Fg 3D scaffolds to promote bone regeneration. Also, we investigated the local and systemic response to these scaffolds at short- and long-term time-points after implantation.

EXPERIMENTAL METHODS

Fg scaffolds were prepared by freeze-drying method as previously described by our group for other materials². Animal work was approved by DGAV. Each Wistar rat (3 months) suffered a femoral critical size bone defect, which remained empty or received Fg scaffolds (n=12/group). Before implantation the scaffolds were neutralized and disinfected by an ethanol series gradient and kept in sterile PBS.

After 6 days (short-term) and 8 weeks (long-term) post-implantation, the animals were sacrificed. The blood (BL), lymph nodes (LN), spleen (SP) and femurs were collected. Some of the femurs (n=5) were processed for histology (H&E and Masson's trichrome staining) and were observed in a light microscope Olympus CX31. Gene expression analysis of inflammatory and bone-related markers was analysed at the defect site in the remaining femurs (n=7). Immune cell populations from BL, LN and SP were freshly isolated and analysed in a FACSCanto. The results were analyzed with FlowJo. Pro-inflammatory cytokines in plasma were also analysed by ELISA. Statistical analysis was performed using Prism software.

RESULTS

At 6 days post-implantation, local gene expression analysis at the bone defect revealed a significant increase in IL-6 and IL-8 levels for both, empty- and Fg-groups of animals when compared with non operated animals, while IL-1B remained constant. An increase of VEGF and TGF-B1 was also detected. At the same time-point post-implantation, TGF-B1 concentration in plasma was significantly increased in the “empty”-group of animals, while at 8 weeks post-

implantation no differences were observed between the groups of animals. The pro-inflammatory cytokines TNF-a, IL-6 and IL-17a were not detected in plasma, at either time point.

Also, Fg scaffold implantation correlated with changes on the proportions of immune cells at the systemic level. A reduction of myeloid cells (CD11b⁺) and B cells, with a concomitant increase on T cells, was particularly significant in SP at 6 days post-implantation. Fg also led to less NK and NKT cells in BL. Interestingly, BL, LN and SP Mac-1⁺ (CD18⁺/CD11b⁺) cells were significantly decreased in animals implanted with Fg scaffolds, while more TCR^{dim} T cells were found in LN of the animals with Fg implants. Moreover, BL myeloid cells (CD11b⁺) showed an activated phenotype (MHC^{high}) in Fg implanted animals.

Histological evaluation showed that Fg scaffolds eased cell migration. The increased infiltration of connective tissue at periphery of the defect in Fg-group correlated with a decreased defect size at day 6. By 8 weeks post-implantation Fg scaffolds were replaced by bone tissue.

CONCLUSION

Fg scaffolds promote bone formation after 8 weeks of implantation. A mild inflammatory response was observed 6 days after injury, either with or without Fg implants, when compared with non-operated animals. Moreover, alterations in immune cell proportions and their activation status, at an early time-point correlate with increased bone formation at a later stage.

INTRODUCTION

Mesenchymal stem cells (MSCs) respond to nanoscale surface features through changes in growth and differentiation. In this talk we will discuss the contribution of nanoscale topography to MSC differentiation and self-renewal. MSCs in their niche undergo growth and differentiation in response to regenerative demand – this is at odds with static materials approaches where either growth or differentiation is influenced. Thus, dynamic surfaces that can be used to control stem cell growth and differentiation under user control will be presented.

Furthermore, the potential role of materials in stem cell discovery will be discussed. MSCs are adaptive to their environment and tune e.g. their metabolic response to different extracellular cues. Using tissue-matched hydrogels with control of elastic moduli coupled to analysis of metabolic adaptation and lineage specific depletion, data on selection of bioactive metabolites that drive MSC differentiation will be discussed. We will further extend some of this data to perivascular stem cells (pericytes).

RESULTS AND DISCUSSION

Figure 1. Nanoscale order is critical to MSC differentiation. Using electron beam lithography 120 nm diameter pits with 300 nm spacing were produced in PMMA. Where the pits were formed in an ordered square (SQ) lattice or with random placement little osteospecific differentiation was noted. If, however, small levels of disorder (near SQ, NSQ) were added (± 20 nm and ± 50 nm offset from centre position) then rapid osteogenesis was noted.

Figure 2. The way MSCs adhere to nanotopography alters depending if the surface controls growth or differentiation. These adhesion changes drive metabolomics changes that can be used to identify regulators of growth and differentiation.

Figure 3. NSQ nanotopography promotes co-localisation of adhesions and the BMP receptor BMPR1a helping to enhance osteogenesis.

MSC adapt to their physical environment and this can be exploited for cell engineering purposes. We can use materials as tools to study MSC growth and differentiation. Furthermore, through following natural adaptive processes of the metabolome, we can identify signalling hubs involved in stem cell control and also identify bioactive metabolites that can be used as drugs to target the perivascular / MSC niches.

Photo-Crosslinkable Biopolymers Targeting Stem Cell Differentiation: the Candidature of Gelatin

Ine Van Nieuwenhove¹, Sandra Van Vlierberghe^{1*}, Winnok De Vos², Achim Salamon³,
Kirsten Peters³ and Peter Dubrue¹

¹ Polymer Chemistry and Biomaterials Group, Ghent University, Belgium, sandra.vanvlierberghe@ugent.be

³ Junior Research Group Cell Biology, University of Rostock, Germany

INTRODUCTION

Organ or tissue transplantations are often crucial for patients suffering from untreatable diseases. Interestingly, regenerative medicine is an emerging research field which may offer novel treatments for patients suffering from failing organs or tissues¹⁻⁴. The present work is situated in the tissue engineering field as it focuses on the development of biomaterials to be applied as scaffolds to support the adhesion, the proliferation and the differentiation of adipose-tissue derived stem cells.

EXPERIMENTAL METHODS

Synthesis of photo-crosslinkable biopolymers

Photo-crosslinkable gelatin- and starch-based hydrogel precursors and their corresponding networks have been synthesized in combination with bio-active, extracellular matrix (ECM) compounds including fibronectin and aggrecan. Subsequently, the materials developed were characterized in depth via HR-MAS ¹H-NMR spectroscopy, IR mapping and rheology.

In vitro biocompatibility assays

Mesenchymal stem cells were derived from adipose tissue through liposuction followed by cell-seeding onto the scaffolds developed. In order to proof both the adipogenesis- as well as the osteogenesis-supporting potential of the materials, hydrogel films with a thickness of 1 mm were developed and compared regarding material characteristics and behaviour of stem cells *in vitro*. Moreover, fibronectin- and aggrecan-coatings were applied on the gelatin hydrogel films in order to evaluate their impact on the adipogenic as well as the osteogenic potential of the hydrogels developed.

Multi-parametric analysis of the cellular architecture

To monitor the cellular architecture, a number of characteristic cytoskeletal elements, such as actin filaments, intermediate filaments and tubulin, were (immuno-)labelled in order to acquire a profound understanding on how the composition and the accompanying mechanical properties of these substrates affect cell behaviour of adMSCs. The cell-matrix interactions were quantified through staining and by an automated counting procedure to assess the focal adhesion points.

RESULTS AND DISCUSSION

The mechanical strength and the cell-interactivity of the scaffolds were achieved by the self-structuring property of the biopolymer gelatin, while amylose/amylopectin (cfr. starch) and the ECM polymers influenced the cell

adhesion, proliferation and the migration processes. The presence of an additional starch phase in the gelatin matrix resulted in a decrease of the cell adhesion, with locally even cell detachment.

Figure 1 Vital cell staining on gelatin hydrogels revealing homogeneous cell coverage (A and B) and gelatin-starch hydrogels revealing C) a high density cell-region and D) a low density cell region with partial cell detachment (green = living cells, red = dead cells, blue = nuclei). Scale bars: 100 μ m.

Moreover, the hydrogels developed allowed *in vitro* adipogenic and osteogenic differentiation of the adMSC. The differentiation supporting potential increased upon increasing the crosslinking degree and thus the mechanical properties of the gelatin hydrogels for both adipogenic as well as osteogenic differentiation. The presence of a starch phase was observed to temper the differentiation supporting potential.

CONCLUSIONS

The hydrogels developed were shown to be biocompatible and supported cell adhesion of adipose-tissue derived mesenchymal stem cells. In addition, by varying the mechanical properties of the gelatin hydrogels developed, both adipogenic as well as osteogenic differentiation could be upregulated.

Investigating the “Bone-shell divide”: Pearl oyster shell topography as a means of directing stem cell behaviour

Enateri V. Alakpa^{1,2}, Matthew J. Dalby¹ and Maggie Cusack²

¹Centre for Cell Engineering, University of Glasgow, UK

²Geological & Earth Sciences, University of Glasgow, UK. Enateri.Alakpa@glasgow.ac.uk

INTRODUCTION

Proteins such as perlustrin, typically found in the nacreous (mother of pearl) layer in molluscs, bear a 40% homology to insulin growth factor binding protein (IGF-BP). In addition, it also exhibits the ability to form complexes with insulin growth factor¹. This observation leads to the hypothesis that biomineralisation systems in molluscs and mammals may have common components in their phylogenetic lineage originating from a common ancestor. The juxtaposed use of calcium carbonate polymorphs (aragonite and calcite) in molluscs and calcium phosphate ($\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$) in mammals for biomineralisation processes is generally referred to as the “bone-shell divide”². Common physical and functional characteristics between bone and shells such as their strength and mechanical qualities provide an incentive to consider mimicry of aragonite and calcite properties for the subsequent design of synthetic biomaterials. This study explores the role that topographical detail of nacreous aragonite and prismatic calcite (referred to as ‘nacreous’ and ‘prismatic’ henceforth) has on the physical characteristics of human mesenchymal stem cells and whether these features in their own right contribute to instructing lineage commitment on differentiation.

EXPERIMENTAL METHODS

Physical and surface characteristics (roughness) of the pearl oyster shell (*Pinctada maxima*) were ascertained using atomic force & scanning electron microscopy. Nacreous and prismatic shell surface nanopatterns were embossed onto polydimethylsiloxane (PDMS) to form inverse patterned stamps used to imprint onto polycaprolactone (PCL) substrates. Mesenchymal stem cells acquired from human bone marrow were subsequently cultured on the patterned PCL substrates and the cells assessed for differentiation after 2 weeks by quantifying gene expression of known lineage biomarkers using RT-PCR.

RESULTS AND DISCUSSION

PCL replicas of nacreous and prismatic surfaces of *Pinctada maxima* were imaged using SEM (Figure 1A & B) and characteristic roughness determined using AFM. The prismatic surface had an average roughness of 102.8 nm compared to 26 nm for the nacreous surface rendering the latter surface as relatively smoother. Cells subsequently cultured on each of the surfaces showed slightly differing physical characteristics with cells cultured on the nacre topography observed as wider spread than the prismatic. These differences in morphological properties are likely to impact how the cells interpret their microenvironment and as such, phenotypic marker for

differentiation was assessed by RT-PCR. Cells on the nacre topography had shown significant up-regulation of the osteogenic marker osteopontin (OPN) suggesting that this topography favours osteoblasts formation. Cells cultured on the prismatic topography however had shown significant increase in the self-renewal marker ALCAM indicating that the prismatic topography is influential in retaining ‘stemness’ (Figure 1C).

Figure 1: Scanning electron microscopy image of nacreous (A) and prismatic (B) surfaces of the pearl oyster shell. RT-PCR analysis of mesenchymal stem cells cultured on PCL topography replicas (C) showed increased expression of self-renewal marker ALCAM for cells on the prism surface while those cultured on the nacre surface undergo osteogenesis as shown through increased osteopontin (OPN) expression. Scale bar – 100 µm.

CONCLUSION

While the potential of nacre to drive osteogenesis in progenitor cells is known³, this study shows that it is also the case in MSCs and that this characteristic of nacre is, in part, due to the nanotopographical detail of nacre. However, the calcite or prismatic counterpart of the pearl oyster shell, although in itself does not support cell adhesion or growth, has shown that replicating its topography alone can be a potentially useful biomaterial design for maintaining self-renewal properties of stem cells.

INTRODUCTION

The generation of physiological-like microvascular systems is required for the development of both *in vivo* long-lasting blood vessels and advanced *in vitro* models to replicate biological phenomena involving the interaction between capillaries and organ-specific tissues^{1,2,3}. However, the generation of a functional vasculature involves the recruitment of mural cells which provide mechanical stability and secrete factors affecting the endothelium homeostasis, e.g. angiopoietin (Ang)-1 and transforming growth factor (TGF)- β 1^{4,5}. The present study is focused on the generation of functional, perfusable 3D human microvascular networks, co-culturing endothelial cells (ECs) and bone marrow-derived human mesenchymal stem cells (BM-hMSCs) within a microfluidic device. Particularly, we analyze the role of Ang-1 and TGF- β 1 on mural cell-like recruitment and the resulting microvascular network structure.

EXPERIMENTAL METHODS

A microfluidic device consisting of two lateral media channels and a central gel channel was adopted. Primary human umbilical vein ECs were mixed with BM-hMSCs in a 2.5 mg/ml fibrin gel reaching 3×10^6 and 1.5×10^6 cells/ml densities, respectively. Selected microdevices were supplemented with 100 ng/ml Ang-1 or 1 ng/ml TGF- β 1 to analyze their effect on microvascular network and BM-hMSC mural cell commitment. Alpha smooth muscle actin (α -SMA), SM22 α , vascular endothelial-cadherin and zonula occludens-1 markers were assessed by immunofluorescence. The Fiji 2D skeletonize plugin was applied to quantify number of branches, average branch length and total network length (day6). Vessel permeability was quantified with 70 kDa dextran.

RESULTS AND DISCUSSION

The ability of BM-hMSCs to get a mural phenotype was increased in the presence of ECs. The α -SMA signal was 4.72 ± 0.99 fold higher with VEGF+Ang-1 whereas VEGF+TGF- β 1 devices showed values 5.06 ± 0.79 fold higher when normalized to VEGF only devices. However, addition of Ang-1/TGF- β 1 exerted a strong influence on BM-hMSC phenotypic transition only when BM-hMSCs were in direct contact with ECs. EC monoculture was compared to EC+BM-hMSC showing less branches (93.8 ± 9.4 vs.

142.2 ± 5.9), larger diameters (84.2 ± 2.7 vs $40.8 \pm 1.5 \mu\text{m}$) and shorter networks (10.13 ± 0.39 vs $12.86 \pm 0.35 \text{mm}$). While the addition of TGF- β 1 during culture enhanced BM-hMSCs phenotypic transition toward a mural cell lineage, systems with added TGF- β 1 generally resulted in shorter, fragmented networks. Conversely, co-cultures with VEGF+Ang-1 not only promoted formation of microvascular networks with even smaller vessel diameters (36.2 ± 1.6 vs $40.8 \pm 1.5 \mu\text{m}$) but also strongly induced BM-hMSCs mural cell commitment. Dextran perfusion confirmed the presence of patent lumens showing an *in vivo*-like diffusive permeability ($6.7 \times 10^{-7} \pm 2.74 \times 10^{-7} \text{cm/s}$).

Fig 1. α -SMA intensity signal (A) and immunofluorescence (B, green), mural cell-endothelial cell co-localization (C, green: α -SMA), average vessel diameter (D), microvascular network structure (E) and zonula occludens-1 expression (F, green). Red: ECs, blue: nuclei. Bars: 100 μm (B,C,E) and 30 μm (F).

CONCLUSION

The addition of VEGF+Ang-1 was considered the optimal condition, leading to interconnected microvessels surrounded by co-localized α -SMA+ BM-hMSCs with promising applications for *in vitro* models requiring a functional microvasculature.

INTRODUCTION

Electrospun polymeric fibril meshes have been shown to replicate many of the cues and properties of the ECM, as well as having a porous network for the transportation of nutrients and metabolic waste¹. Such meshes have the potential to provide a biocompatible substrate suitable for a range of transplantation therapies including retinal implant applications. However, a most of the polymers used as synthetic tissue scaffolds or cell delivery systems are inherently hydrophobic, which can significantly hinder cell attachment and proliferation. In this work, a thin biodegradable electrospun polymer membrane, developed as a substrate for human embryonic stem cell derived retinal pigment epithelial (hESC-RPE) cells, has been modified via atmospheric pressure plasma processing. The effects that plasma induced changes to the polymer fibre surface properties have on hESC-RPE cell attachment, proliferation and maturation are investigated. Importantly, the conditions required to derive mature and functional RPE monolayer on biodegradable substrate were reported.

EXPERIMENTAL METHODS

Poly-L-Lactide/Caprolactone (PLCL) (PURASORB® PLCL 7015, 70/30 L-lactide/caprolactone) was used to produce the electrospun membrane. A 10% weight by volume (w/v) solution of PLCL, prepared in 9:1 v/v chloroform/dimethylformamide, was electrospun at an applied voltage of 18 kV with a polymer flow rate of 1ml/hour. Fibres were collected in a random orientation for 10 minutes for each membrane. The surface chemistry and topography of the membrane PLCL fibres were modified by exposure to an atmospheric pressure dielectric barrier discharge (DBD) treatment regime in air. Contact angle measurements, using glycerol as the test droplet, were obtained for DBD treated electrospun fibres and untreated fibres. Changes to the microstructure and surface chemistry were assessed by scanning electron microscopy (SEM), atomic force microscopy (AFM), X-ray photoelectron spectroscopy (XPS) and Fourier transform infrared spectroscopy (FTIR).

The propensity of hESC-RPE cells² to attach and proliferate on untreated and DBD treated electrospun PLCL membranes was examined by both cell counting and the AlamarBlue® cell proliferation assay. Cell adhesion and maturation were evaluated with light microscopy imaging, immunofluorescence staining and gene expression analysis. Development of epithelia barrier properties and the integrity of the RPE

cell monolayer on the PLCL membranes were examined with transepithelial electrical resistance (TER) measurements. The functionality of hESC-RPE cells on DBD-treated electrospun PLCL fibres was also assessed with an *in vitro* phagocytosis assay.

RESULTS AND DISCUSSION

All PLCL electrospun membranes had an unaligned fibre orientation with an extremely porous structure. DBD plasma treatment increased both the surface roughness and the oxygen to carbon ratio on the fibre surfaces. As a consequence, the surface treatment significantly reduced the surface wettability of PLCL electrospun membranes.

DBD plasma treatment of electrospun PLCL scaffolds had a beneficial effect on hESC-RPE cell attachment and proliferation. Cell count and proliferation assay data indicated that there were significantly higher numbers of hESC-RPE cells on the DBD plasma treated materials compared to the untreated membranes. Surface treatment of the membranes provided for the formation of confluent and uniform hESC-RPE monolayers; untreated films failed to support proper cell attachment and proliferation. Moreover, hESC-RPE cells on DBD plasma treated membranes showed the presence of a polarized mature epithelium and exhibited phagocytic activity.

CONCLUSION

Atmospheric pressure plasma treatment is an effective method to enhance the cellular attachment, proliferation and maturation of clinically relevant hESC-RPE cells on electrospun PLCL membranes. The work reported here has established for the first time that DBD plasma modified PLCL electrospun membranes in combination with hESC-RPE cells could potentially be used as a tissue engineered construct for retinal applications.

Functionalising natural polymers with alkoxysilane coupling agents for tissue engineering applications

Louise S Connell¹, Frederik Romer², Oliver Mahony¹, Mark E Smith^{2,3}, John V Hanna², and Julian R Jones¹

¹ Department of Materials, Imperial College London, UK, l.connell10@imperial.ac.uk

² Department of Physics, University of Warwick, Gibbet Hill Rd, Coventry, CV4 7AL, UK

³ Vice-Chancellor's Office, University House, Lancaster University, LA1 4YW, UK

INTRODUCTION

Hybrids, with nanoscale interpenetrating organic and inorganic networks, show promise as tissue regeneration materials. The natural polymers gelatin, chitosan, and poly(γ -glutamic acid) (γ PGA) have been incorporated into the silica sol-gel process to produce bioactive hybrids that proliferate osteoblast-like cells¹, support mesenchymal stem cells², and improve nerve fibre regeneration³.

The success of hybrids in tissue regeneration depends upon their mechanical and degradation properties, which in turn rely upon covalent bonding between the networks². 3-glycidypropyl trimethoxysilane (GPTMS) is one of the most used coupling agents to introduce covalent bonding. It contains an epoxide ring, proposed to react with nucleophilic groups of natural polymers such as amines and carboxylic acids, and an alkoxysilane group which co-condenses with silica precursors to form an inorganic network.

There is dispute over whether or not the epoxide reacts with the nucleophilic groups as the reaction conditions are typically acidic and nucleophilic character will be reduced due to protonation^{4,5}.

The aim of this work was to use a range of NMR techniques to identify and quantify the extent of reaction of GPTMS with chitosan, γ PGA, and gelatin under typical functionalisation conditions.

EXPERIMENTAL METHODS

Solid state NMR samples were prepared by reacting chitosan with GPTMS for up to 24 h in deionised water at pH 2 and 4. The reaction was quenched in liquid nitrogen and freeze dried. ¹⁵N MAS NMR spectra were acquired to determine if a reaction occurs at the primary amine of chitosan and ²⁹Si MAS NMR was used to quantify the silica species present. Identification of side reactions and quantification of co-products under different pH conditions was carried out using solution state ¹³C, ¹H, quantitative ¹H-¹³C HSQC, and ¹H-¹³C HMBC NMR. Spectra were acquired for chitosan functionalised for 24 h at pH 2, 4 and 6, and for γ -PGA and gelatin functionalised for up to 48 h at pH 4.

RESULTS AND DISCUSSION

Splitting of the primary amine peak in ¹⁵N MAS NMR (Fig. 1) combined with solution state ¹H, ¹³C and HSQC NMR established that a reaction occurred between the epoxide ring of GPTMS and the primary amine in chitosan. A reaction also occurred between water and the epoxide, producing a diol. Low pH accelerated the reaction but only 20 mol% secondary amine was formed (relative to total products), irrespective of pH (Fig. 2). This is an important result that shows that acidic conditions do not inhibit the reaction as previously assumed, but that the efficiency is very low. Characterisation of the reaction between γ PGA and

GPTMS showed that the epoxide ring also reacted with carboxylic acid groups and it was confirmed with HMBC that the final product was an ester. Careful analysis of the complicated ¹H NMR spectra of gelatin before and after reaction identified specific amino acids that reacted with GPTMS and showed that amino acids containing carboxylic acid groups were favoured. The bonding within the inorganic network was also characterised and will be presented.

Fig. 1 – ¹⁵N MAS NMR of chitosan a) before, and b) after functionalisation for 24 h.

Fig. 2 – Effect of pH on amount of unopened epoxide, diol and secondary amine products after 24 h.

CONCLUSION

Solution state and solid state NMR techniques were used to show that even under acidic conditions the epoxide ring of GPTMS can react with a primary amine, such as in chitosan, to form a secondary amine or a carboxylic acid, as in γ PGA, to form an ester, albeit with low efficiency. To achieve controlled degradation and good mechanical properties, good covalent bonding is necessary. Polymers can be chosen or designed to contain appropriate functional groups for functionalisation and the reaction conditions optimised to achieve hybrid materials for tissue regeneration.

Composition-Structure-Property Relationships for Strontium Borate Glasses for Biomedical Applications

Muhammad Sami Hasan and Daniel Boyd <mailto:sami.hasan@dal.ca>

Department of Applied Oral Sciences, School of Biomedical Engineering, Dalhousie University, Halifax, NS, Canada

INTRODUCTION

Borate glasses are attractive as medical materials based on bioactivity and degradability¹. Doping with various network formers (e.g. SiO₂, P₂O₅) may help to tailor their durability and bioactivity in terms of therapeutic effects or conversion into hydroxyapatite^{1,2}. However, correlation between structure and properties, especially the release kinetics its extremely difficult in a glass containing more than one network former. Vitreous borate glass is made of B₂O₃ rings that break into BO₃ and BO₄ units with the addition of network modifiers. Alkali and alkaline earth metal oxides have been incorporated in biodegradable glasses to control their degradation rate and to induce bioactivity². In this project, strontium for its therapeutic effect on bone cells, and titanium, for its antibacterial properties, alongside their effects on durability have been selected as modifiers of pure borate network. Investigations into chemical-structural changes, thermal properties variations, effect on durability, quantities of ions released and cytocompatibility per systematic compositional changes have been evaluated.

Table 1. Glass codes, actual compositions, thermal properties and density

Composition	Actual composition	T _g (°C)	T _c (°C)	T _m (°C)	ρ g/cm ³

EXPERIMENTAL METHODS

A melt-quenching technique was used to produce 11 glass compositions using: B₂O₃, SrCO₃, TiO₂ and Na₂CO₃. The glasses were ground using an automated grinder and sieved to 45-90µm. Glass rods were melt-casted in a graphite mold preheated at 5°C above T_g and cut into discs using a diamond saw. Digesting the glass in strong acid and detecting constituent oxides in an ICP-AES provided the actual compositions. The amorphicity of all the glass compositions was confirmed using X-ray diffraction spectra. ¹¹B magic-angle spinning nuclear magnetic resonance studies was carried out on a Bruker Avance NMR spectrometer. The thermal characteristic temperatures were characterized by a differential scanning calorimeter operated at a heating rate of 10°C/min from 25 to 1100°C. Density of glasses was measured using He-Pycnometer. Glass discs (9mm diameter, 4mm thick) were immersed into vials containing 30ml of phosphate buffered saline and incubated in an incubator at 37°C for 21 days. At specific time points, pH was measured, the discs were taken out of their respective containers and blot-dried and weighed. Glass extracts were prepared in tissue culture water at a ratio of 0.2g/ml incubated for up to 28 days at 37°C in a shaker incubator, agitated at 2Hz. The

elution-products were detected using ICP-AES. In vitro cytocompatibility of L929 mouse fibroblast was evaluated using the MTT assay with evaluations being on the basis of indirect exposure via the same extracts prepared for ICP-AES.

Figure 1. Degradation rates for glasses in series S1.

RESULTS AND DISCUSSION

Borate glasses in system (S1: 70B₂O₃-30-XSrO₂-XTiO₂ and S2: 70B₂O₃-20SrO₂-10-XNa₂O-XTiO₂, where X=2,4,6,8,10 in mol%) were prepared. The XRD traces confirmed the amorphicity of the glasses. Compositions of the glass were within 5-8% of theoretical compositions (Table 1). For glasses S1, a downward trend and for S2 no significant change in T_g was observed with increasing Ti content. Density appeared to have reduced in S1 and unchanged in S2. In S1, an increased solubility was observed with increased Ti content. However, no change in durability was observed for S2 (Fig 1). The pH was observed to change from 7.5 to 8.1-8.5 during the study. NMR investigations revealed structural changes in the glass series with increasing Ti content. The peak positions BO₃ (0.6ppm) and BO₄ (14ppm) did not change significantly. However, BO₃/BO₄ ratio increased suggesting the network-forming role of TiO₂, which explains the observed changes in the properties (thermal, density) in S1. Varying SrO content predominantly controlled the degradation rates, which in turn controlled the ion release kinetics. For both S1 and S2 a burst release up to 7th day and then a plateau due to saturation for all ions was observed which was directly related to the durability and the glass composition. Cytocompatibility assessments via MTT assay revealed no toxicity for S1 and significant toxicity for some compositions in S2.

CONCLUSION

Borate glass with controlled durability and continuous release of therapeutic levels of ions can be prepared. Alkaline earth metal is more effective in controlling the durability. Variation of modifiers/intermediates induced the structural changes in the glasses that lead to the change in characteristic properties.

Unravelling the Structure of Bioglass® through the Application of Diffraction Techniques

Richard Martin

School of Engineering & Aston Research Centre for Healthy Ageing, Aston University, UK R.A.Martin@Aston.ac.uk

The atomic-scale structure of Bioglass® and its derivatives has been investigated using neutron and X-ray diffraction. Structural sites present in these glasses will be intimately related to their release properties in physiological fluids such as plasma and saliva, and hence the bioactivity of the material. Detailed structural knowledge is therefore a prerequisite for optimising material design.

INTRODUCTION

Melt-quenched silicate glasses containing calcium and phosphorous are of great importance due to their ability to bond chemically to bone and to stimulate new bone growth¹. Under physiological conditions the glass slowly dissolves, releasing calcium and phosphorous into solution. This forms an amorphous calcium phosphate layer which then crystallises into hydroxyapatite. The first key step in the bioactivity is therefore the dissolution of glass. Consequently, the atomic-scale structure of bioactive glasses and its effect on chemical durability and bioactivity has been the focus of much attention^{2,3}. However the addition of an alkali metal, an alkaline-earth metal as well as a second network former in the form of phosphorous means that the generation of a structural model of Bioglass and its derivatives is challenging.

In order to be able to model and predict the behaviour of these materials, and ultimately improve their design, it is necessary to understand the local structure of the glasses. The present work helps shed light on the atomic scale structure of Bioglass.

EXPERIMENTAL METHODS

Neutron diffraction spectra were collected using D4C diffractometer at the Institut Laue-Langvin, Grenoble and the GEM diffractometer at the ISIS spallation neutron source at the Rutherford Appleton Laboratory. Data corrections were undertaken to remove the background scattering, normalise the data, correct for absorption, inelastic and multiple scattering effects and subtraction of the self-scattering term. The individual pair-wise structure factors were then modelled to provide detailed information (interatomic distances, coordination numbers and the degree of disorder) on the atomic scale structure.

RESULTS AND DISCUSSION

The real space total diffraction patterns for Bioglass and strontium substituted Bioglass are shown in Figure 1. The total diffraction pattern was deconvolved and modelled to give the individual correlation functions. As a result the asymmetry of Na and Ca atoms, predicted by computer models has been experimentally confirmed^{4,5}. In addition the local environment of several modifying ions such as Sr, Ti⁶, Ni and Co⁷ has been examined. By understanding their structure and the role each of these

elements play in the glass formation (e.g. network / modifier) it is now possible to predict the effect these elements will have on the solubility and therefore bioactivity.

Figure 1. The real-space diffraction data for the total diffraction patterns, $T(r)$. The broken curves represent the experimental data and the solid curves are the resultant fits.

CONCLUSION

Neutron diffraction studies have provided direct experimental information on the atomic scale structure of bioactive glasses and their derivatives. Data provided indicates how particular modifiers should be incorporated into glasses to maintain the desired solubility

INTRODUCTION

Bioactive glasses are widely used in bone tissue engineering (BTE) since they can develop strong bonds with bone through the formation of a hydroxyapatite (HA) layer¹. Within these materials, sol-gel-based bioactive glasses (SGBGs) are attractive due to their enhanced bioactivity and resorbability and their capacity of being functionalised with a large variety of moieties²⁻³.

Surface functionalisation is an interesting approach to load drugs into the material and allow their release in a controlled manner³.

The aim of this study is the development of new SGBGs for 3D porous scaffolds and functionalisation of their surface by two different methods⁴⁻⁵ in order to enhance the drug delivery capability.

EXPERIMENTAL METHODS

Bioactive glass scaffolds with composition (in mol%) 60SiO₂ 30CaO 5Na₂O 5P₂O₅ were prepared by the sol gel method and the foam replica technique. Scaffolds were characterised by scanning electron microscopy (SEM) and μ -CT, in order to evaluate the macrostructure and porosity and by transmission electron microscopy (TEM) and N₂ adsorption porosimetry using the Brunauer-Emmett-Teller (BET) approach for mesoporosity characterisation. Bioactivity was revealed by Fourier transform infrared spectroscopy (FTIR) characterisation of the scaffolds after SFB immersion.

After heat treatment at 700°C, the scaffolds surface was functionalised by post-condensation of aminosilane, following the reaction shown below:

A second step was considered to avoid steric interference by adding a spacer and allowing an optimal loading of the model drug.

Both systems were loaded with a model drug, and the drug release capabilities were studied in two different media by UV-Vis spectroscopy.

RESULTS AND DISCUSSION

Scaffolds exhibited the required macropore size (~500 μ m) as well as high and interconnected porosity, of up to 90% as shown in Fig.1 (a-c). TEM (Fig.1 d) revealed the mesoporosity, confirmed by BET analysis (pore size: ~4nm; S_{BET} =150m²/g). Both porosities are features required by scaffolds for BTE and drug delivery applications¹⁻².

Figure 1. Images of scaffold a,b)SEM micrographs, c) μ -CT reconstruction, d)TEM micrograph

Amino-functionalisation of the surface was confirmed by zeta potential measurements, ninhydrine test as well as by element mapping in SEM.

The different drug release profiles showed that by surface functionalisation it was possible to achieve a reduced initial burst release of the drug in the tested media and a long-term sustained release.

CONCLUSION

According to SEM and μ -CT reconstructions, 3D porous scaffolds were successfully prepared, exhibiting macro- and mesoporosity. Furthermore, amino-functionalised surface allowed the system to exhibit a sustain release of the model drug compared to non-functionalised scaffolds.

INTRODUCTION. Bioceramics are well-known materials used as bone substitutes¹. 3D printing techniques allow obtaining materials with one or several phases while giving more liberty on the confection of the structure^{2, 3}. Nevertheless, as these materials are intended to interact with the body, it is important to assess their interaction, at first instance, with cells⁴. The objective of this study was to assess the *in vitro* viability, cytotoxicity and apoptosis behaviour of two biomaterials made of wollastonite and an apatite-based glass ceramic (AP40) in interaction with MC3T3 cells.

MATERIALS AND METHODS. Materials were produced by a 3D printing polymer-derived ceramic material process. Briefly, green bodies of preceramic polymers, filled with active and passive ceramic fillers, were printed by a 3D printing process². Subsequently, green bodies were converted to fully ceramic bodies by a heat treatment. This process allowed obtaining materials composed of different contents of wollastonite and AP40 according to two different percentages of starting materials, *i.e.* 20%-80% (S1) and 60%-40% (S2). Materials were obtained on disc shape with 10 mm in diameter by 2 mm in height. Materials were characterized by Scanning Electron microscopy (SEM; Phenom, Germany) for morphology observation. Before any interaction with cells, discs were heat-sterilized at 300 °C for 3 h by using a furnace (HERATharm, Heraeus, Germany). MC3T3-E1, subclone 4, cells (ATCC, USA) were used for the *in vitro* assessment. Culture medium consisted of DMEM (PAA, Germany) with 10 % FBS (PAA, Germany), 50 µg/ml of ascorbic acid (SigmaAldrich, Germany), 5 mM of β-Glycerophosphate (Sigma Aldrich, Germany), 2 mM of L-Glutamine (Gibco, Germany) and 50 µg/ml of Penicillin-Streptomycin (Gibco, Germany). S1 and S2 discs were placed in 24-well plates for 24 h in contact with culture medium before seeding. Then, culture medium was removed, discs were placed in a new well plate and 50,000 cells were seeded on the materials. Cells were allowed to attach for 2 h and then the wells were filled with medium. Interaction was assessed at 3, 7 and 14 days. Three discs per condition, time point and material were assessed (*n* = 3). Cell viability (AlamarBlue®, Invitrogen, Germany), cytotoxicity (CellTox™ Green, Promega, Germany) and apoptosis (Caspase Glo® 3/7, Promega, Germany) behaviours were assessed by using a plate reader (GloMax®-Multi, Promega, Germany).

RESULTS AND DISCUSSION. SEM (Fig. 1) shown that S1 presented a mixture of “round” and “sand-like”

particles. After the 14 days of medium immersion S1 did not present any important changes on its morphology. S2 presented a double morphology aspect with a peripheral part presenting a morphology like S1 and at the center a mixture of this morphology and acicular crystals. These crystals created a discontinuous structure. Crystals seemed to grow thicker with the immersion time in medium. The different morphologies presented by S1 and S2 may be related to their compositions. Alamar Bleu® assay demonstrated a good cell growth over the 14 day period on both materials. S2 material presented a mean reduced value for the cell number at 3 days and 7 days but at 14 days it increased in a significant way. CellTox Green assay indicated, within the time period tested, the non-cytotoxicity of the materials for the cells. Caspase activity assay indicated a higher mean values for the S1 group at 3 days and 7 days. However, after 14 days S1 and S2 activities were similar.

Fig 1. SEM images of S1 (left) and S2 (right).

CONCLUSION. Biomaterials produced by 3D printing techniques and made of wollastonite and AP40, *i.e.* S1 and S2, allowed cells to grow without creating a toxic environment to the cells. No apoptotic behaviour was observed. Further analysis need to be performed on these types of materials to assess their cellular signalling expression. However, these results prove the biocompatibility of these materials and open doors for their feasibility to be used as bone substitutes.

ACKNOWLEDGMENTS. Authors thank the DFG (Grant KN 377/8-1) for its financial support, the technical assistance of Mrs. A. Kopp and the invaluable help of Prof. Frankenberger and Prof. Roggendorf for the SEM imaging.

Fabrication and Characterization of Electrospun PHB/PCL/Sol-gel Derived Glass Hybrid Scaffolds

Yaping Ding^{1*}, Teresa Müller¹, Judith A. Roether¹, Dirk W. Schubert¹, Aldo R. Boccaccini²

^{1*}Institute of Polymer Materials, University of Erlangen-Nuremberg, Germany, yaping.ding@fau.de

²Institute of Biomaterials, University of Erlangen-Nuremberg, Germany

INTRODUCTION

Polyhydroxybutyrate (PHB) and polycaprolactone (PCL) are both biocompatible and biodegradable biopolymers [1]. Silica containing biomaterials including bioactive glasses and biopolymers with Si ion releasing ability are favourable for bone and connective tissue restoration [2]. Unlike bulk blending of immiscible PHB and PCL which leads to phase separation and thus great loss of mechanical properties, in our preliminary study, electrospun PHB-PCL blend fibermats were produced which combine the high tensile strength and stiffness of PHB and the flexibility of PCL. PHB/PCL/sol-gel derived glass fibrous scaffolds were fabricated through electrospinning and sol-gel method in the present work. The study aims to develop an organic-inorganic hybrid scaffold, which is expected to attain the most crucial properties required for bone regeneration, namely suitability mechanical strength, hydrophilicity, bioactivity and osteoconductivity and to compensate the drawbacks and limitations of the single components [3].

EXPERIMENTAL METHODS

TEOS, TEP, EtOH, H₂O and CaCl₂·2H₂O with the molar ratio of 1: 0.133: 2: 2: 0.6 were used to prepare the 58S glass sol under an acid catalyst. PHB and PCL (w/w=7:3) were blended and dissolved in chloroform and dimethylformamide (v/v=8:2). Glass sol was added to the polymer solution and fed into the syringe for electrospinning. The operational parameters were 2 ml/h, 8 kV and 15 cm. All obtained samples were dried in a vacuum oven for further characterization. Properties including morphology, mechanical strength, thermal and chemical changes, bioactivity and biological properties were investigated. Samples were named by polymer and inorganic weight ratio, such as P1B0, P20B1 and P5B1.

RESULTS AND DISCUSSION

Hybrid scaffolds with an inorganic ratio from 0 to 20 wt%. were successfully fabricated. Figure 1 shows two typical morphologies of P5B1 produced with solution concentrations of 5% w/v (a) and 2.5% w/v (b), which represent normal non-woven and honeycomb like structures, respectively.

Figure 1. P5B1 fibermats obtained at solution concentrations of 5% w/v (a) and 2.5% w/v (b).

Table 1 shows the basic physical properties of the

fibermats. As the content of inorganic component increased, the fiber diameter and porosity increased, whereas the tensile strength decreased. The wettability switched from hydrophobic to hydrophilic with addition of the silicate component.

Table 1. Physical properties of hybrid fibermats fabricated using 2 ml/h, 8 kV, and 15 cm.

Sample	Diameter/ µm	Tensile strength/MPa	Porosity /%	Contact angle/ °
P1B0	0.7±0.2	2.8±0.3	82.9	129±1
P20B1	0.9±0.3	2.2±0.2	85.1	0
P5B1	1.2±0.2	1.9±0.2	88.8	0

The incorporation of bioactive glass in fibermats was confirmed using FTIR as shown in Figure 2. The broad band around 3400 cm⁻¹ indicates the formation of hydroxyl groups. The band observed between 500 cm⁻¹ and 800 cm⁻¹ (in P5B1) is due to the addition of sol-gel glass.

Figure 2. FTIR spectra of pure polymer fibermats and hybrid fibermats were presented.

The bioactivity and biological properties of the hybrid scaffolds are under investigation.

CONCLUSIONS

PHB/PCL/sol-gel derived glass hybrid scaffolds were fabricated by electrospinning. With varying solution concentration, normal non-woven fibermats and honeycomb-like structures were obtained which are attractive scaffold architectures. In addition, with varying silicate content, the mechanical properties, porosity and wettability of the scaffolds were altered.

Development of a Competitive Calcium Phosphate Cement in a Crowded Marketplace

Philip Procter

Medical Device Industry Consultant, 01220 Divonne les Bains, France consultphilipprocter@gmail.com

INTRODUCTION

For many orthopaedic practitioners biomaterials are the hoped for bridge between the limit of the performance of metallic implants and the unmet needs in the patient treatment. Despite a huge number of biomaterials developments over the last 30 years very few biomaterials have made it from research bench to operating theatre outside of Calcium phosphate (CaP) and PMMA cements¹. Even fewer have clinical evidence of efficacy in a clinical indication². It is essential to have clearly defined unmet needs at the outset rather than to start from an existing technology and try to find applications. The present paper is a case study of the development of a commercially successful CaP Cement, the points of learning and thoughts for the future.

METHODS

The unmet needs for CMF, Trauma and Orthopaedic applications were obtained from customers already using a proprietary CaP, BonesourceTM. A business case was developed around unmet needs and value to clinical users. An external benchmark was defined, NorianTM. The CaP formulation goals were determined from the Voice of Customer (VOC). The primary focus was setting time and wet field properties whilst needs such as ease of mixing, strength, speed of remodelling were also considered. Studies were undertaken to determine acceptable mixing and working times, as well as the desired setting time in a representative range of clinical scenarios. As there are no established methods for some of the parameters eg wet field properties it was necessary to develop original tests to evaluate these. Preclinical studies were undertaken to provide data to support regulatory submissions as a non-load bearing void filler. As an additional goal the project aimed to establish screw augmentation as a new approved regulatory claim.

RESULTS AND DISCUSSION

Preclinical benchmarking in a lapine distal femoral defect model³ showed that the physicochemical and biological properties of the newly developed calcium phosphate cement were comparable with two other commercially available CaP's at 24 h, 6 weeks, 26 weeks, and 52 weeks. The intended clinical performance was assessed by clinicians in an animal test model. The setting time and wet field properties compared very favourably with the CaP benchmarks chosen. The data submitted both in EU and US confirmed approval as a non-load bearing void filler. The preclinical test data for the screw augmentation was accepted by the Notified body in Germany. However the FDA submission was achieved and augmentation of screws with CaP cements remains *off label* use in the

USA. Reimbursement for the combination of a screw and a CaP cement was established in Germany.

POINTS OF LEARNING

There were a number of learning points in the project. These included: formulation, sterilisation and delivery device issues and these will be reviewed.

For CaP cements in general there are still unmet needs: 1) Strength and load sharing potential in combination with screws and locked plates. 2) The long term remodelling remains a concern for most clinical users 3) the ability to combine with antiporotic and antibiotic agents are clinically desired. 4) The lack of specialty cannula eg for use with hip fracture devices, limits the clinical utility. 5) Easy mixing and handling in the operating room is still not generally available.

Biomaterials developers do not focus on these issues and Industry does not invest in the necessary research so progress toward better clinical outcomes is slow at best. In the author's opinion companies that invest in differentiating with clinical claims that produce measurably different clinical performance outcomes will ultimately win in the commercial marketplace. In the future biomaterials will have to be developed that have clinical indication specific properties for use in combination with indication specific devices; these will have to be approved indication by indication with an evidence based approach.

CONCLUSIONS

A case study of a commercially successful CaP cement, HydroSet is presented that has advantages in intraoperative handling. To further develop clinical applications of CaP's will require significant investment and is not without commercial and clinical risk high risk. However there are few signs that either biomaterials developers or the orthopaedic companies are prepared to invest the resources to achieve this.

The Commercial and Clinical Challenges and Opportunities for Advanced Materials in Regenerative Medicine

Kevin M Shakesheff

UK Regenerative Medicine Platform Hub in Acellular Technology, School of Pharmacy, University of Nottingham, NG7 2RD, UK kevin.shakesheff@nottingham.ac.uk

Regenerative medicine can transform many areas of clinical treatment in the future by restoring function tissues within patients. The field encompasses a broad range of product opportunities including drug therapies, biomaterials, cell therapies and engineered tissues. All of these product opportunities share a feature of being more complex in composition and function than the vast majority of pharmaceutical and healthcare products. This complexity allows considerable scope for innovation in the design, manufacture and administration of regenerative medicine products. However, complexity also introduces hurdles to commercial success that must be understood and planned for in research and development programmes.

Advanced materials offer a technology to enhance the efficacy and safety of cell therapies. The UK Regenerative Medicine Platform Hub in Acellular Technologies is a new collaboration to help clinical and industrial groups access materials to accelerate translation of promising candidates into products

This presentation will review the current and future use of materials in the following contexts:

1. Enhancing cell survival and function during and after administration.
2. Co-delivery of pharmaceutical agents and surface chemistry to promote regeneration
3. Creating complex architectures with materials to change cell behaviour
4. Improving manufacturing of cell products (led by the EPSRC Centre for Innovative Manufacturing in Regenerative Medicine).

ACKNOWLEDGMENTS

The research leading to these results has received funding from the European Research Council under the European Community's Seventh Framework Programme (FP7/2007-2013)/ERC grant agreement 227845.

Stratification and Personalisation of Biomaterials and Medical Devices in Musculoskeletal Disease

John Fisher

Institute of Medical and Biological Engineering, University of Leeds, UK
EPSRC UK Centre for Innovative Manufacturing in Medical Devices. J.Fisher@leeds.ac.uk

INTRODUCTION

Stratified and personalised medicine is becoming increasingly important in many areas of healthcare and has the potential to improve the effectiveness and cost effectiveness of many treatments. Stratified and personalised biomaterials and medical devices, is a major opportunity for researchers, manufacturers and clinicians. The recently funded UK EPSRC Centre for Innovative Manufacturing in Medical Devices is starting to address this opportunity, initially in the areas of musculoskeletal biomaterials and implants, with the aim of delivering “the right product, by the right process, to the right patient at the right time” to provide an enhanced standard of reliability, performance and cost effectiveness. This requires new approaches to the design, analysis, simulation, manufacture and pre-clinical testing of biomaterials and medical devices.

METHODS

In the treatment of musculoskeletal disease, the individual patients, the population and the treatments can be characterised, parameterised and stratified using anatomical imaging such as MRI and CT, through analysis and computational predictions of biomechanical function and through quantification of the surgical techniques. The EPSRC centre has identified two key research challenges “functionally stratified design and manufacture” and “personalised near patient manufacture” of biomaterials and implants. Both approaches can potentially deliver better function and patient outcomes. The current research is demonstrated through the description of some of the initial projects. Specifically current work and results will be described for the following research areas.

- Stratified analysis of hip and knee replacements
- Functional simulation of natural joints
- Biological scaffolds derived from natural tissues
- Additive methods for near patient manufacturing.

RESULTS AND DISCUSSION

Stratified analysis of hip and knee replacements:

The function, wear performance and longevity of hip and knee joint replacements are highly dependent on the surgical positioning and patient kinematics. Computational simulation methods have been developed, experimentally validated and parameterised predictions of the effect of surgical positioning and kinematics on wear performance have been defined.

Functional simulation of natural joints:

Novel biphasic computational models of the biphasic contact mechanics and tribology of the natural hip and knee joint have been developed and experimentally validated, and the effect of surgical interventions quantified.

Biological scaffolds derived from natural tissues:

Novel acellular biological scaffolds derived from animal and human tissue have been developed, with properties and function that match human tissue. Examples of the function of biological scaffolds for ligament, meniscus and bone repair are described

Additive methods for near patient manufacturing.

Additive manufacturing methods, which can be used to make patient specific implants close to the patient are being researched and are described.

CONCLUSIONS

New methods for the design, simulation, manufacturing and preclinical testing are needed to deliver stratified and personalised biomaterials and medical devices for musculoskeletal treatments.

Layer-by-layer assembly of collagen and fibronectin for tissue engineering applications

Sara Mauquoy and Christine Dupont-Gillain

Bio and Soft Matter (BSMA), Institute of Condensed Matter and Nanosciences (IMCN), Université catholique de Louvain (UCL), Belgium, sara.mauquoy@uclouvain.be

INTRODUCTION

In vivo, cells are embedded in a complex extracellular matrix (ECM) which gives them signals for adhesion, proliferation and differentiation. Collagen (Col) is one of the major components of the ECM, giving to tissues their structural and mechanical properties. Fibronectin (Fn) is essential for the development of most cell types because it specifically binds integrins, which are transmembrane proteins of cells, to transmit signals from cells to the ECM and conversely. Tailoring biointerfaces with a complex architecture based on these two biomolecules will improve our control of cell-material interactions.

The layer-by-layer (LbL) method is an established approach to design structures with a good control of vertical heterogeneity. Developed by Decher in 1992¹, this method is based on the alternate dipping of a surface in a polycation and a polyanion solution, resulting in surface charge overcompensation at each step and hence in the build-up of multilayered films. Assembling proteins by LbL is however challenging in reason of the polyampholyte character of proteins and of their particular structure. The mechanism of assembly may moreover not only rely on electrostatic interactions, but also on specific interactions, as was reported for the assembly of Fn with gelatin², a compound obtained by Col hydrolysis. Here, we aim at combining Fn and Col in LbL assemblies, to create constructs with vertical heterogeneity and biosignaling properties.

EXPERIMENTAL METHODS

LbL assembly: LbL assembly with Fn and native Col (n-Col) or denatured Col (d-Col) was performed on a polystyrene substrate, in phosphate buffered saline (PBS; pH 7.4), HEPES buffer (pH 7.4) and acetate buffer (pH 5.4). These different buffers were compared to modulate the charge of the proteins and the nature of surrounding ions, thereby gaining a better understanding of the adsorption mechanisms. In some cases, poly(ethyleneimine) (PEI) adsorption was performed prior to the LbL assembly.

Characterization: Quartz crystal microbalance with dissipation monitoring (QCM-D) measures *in situ* the frequency (Δf) and dissipation (ΔD) shifts that can be related to the wet adsorbed mass. Ellipsometry is used to measure the dry thickness of the films, contact angle measurements to characterize their wettability and AFM to examine their morphology.

RESULTS AND DISCUSSION

Comparison of n-Col and d-Col assembly: QCM-D results show that the assembly works better with d-Col compared to n-Col. Fibrillation, which does not happen

with d-Col, could mask some interacting sites of n-Col with Fn and explain this observation.

Role of PEI as a primer: Thicker films were obtained when using PEI as an anchoring layer. AFM images show that such films are rougher.

PEI/(Fn/n-Col)_n films: QCM-D data are presented in Fig.1. Col, a 300 nm-long molecule, may extend in solution, and thus may lead to high shifts in frequency and dissipation. This is particularly the case in acetate buffer, in which Col is more positively charged (pH is further away from isoelectric point) and could be more hydrated. The next step of Fn adsorption likely induces a contraction of the film or a desorption of previously adsorbed matter. Since the thickness measured by ellipsometry for PEI/(Fn/n-Col)₂ is similar in all buffers (≈ 7.2 nm in HEPES and ≈ 6.6 nm acetate buffer; ≈ 5.5 nm in PBS), the differences recorded by QCM-D are mainly attributed to different amounts of water trapped in the films. The combination of results from all techniques indicates successful build-up of multilayers, with a growth which however does not seem sustainable. Further experiments are in progress to characterize the supramolecular organization of the obtained layers.

Figure 1: QCM-D monitoring of the construction of PEI/(Fn/n-Col)₃ films in HEPES buffer (dotted line), PBS (broken line) and acetate buffer (plain line). After each adsorption step of 1h, rinsing is performed during 30 min using the corresponding buffer.

CONCLUSION

By assembling Col and Fn in a variety of conditions, we now better understand their mode of assembly, and we have designed biointerfaces which will be further used to control the differentiation of mesenchymal stem cells.

Alginate-silica hybrid hydrogels through covalent coupling with APTES

Yuliya Vueva¹, Siwei Li¹, Frederik Romer^{2*}, John V. Hanna^{2*}, Julian R. Jones¹

¹ Department of Materials, Imperial College London, UK

^{2*} Department of Physics, University of Warwick, UK, y.vueva@imperial.ac.uk

INTRODUCTION

Bone and cartilage diseases are diminishing the quality of life in an ageing population. To date there is no fully successful surgical or pharmacological treatment which has led to considerable interest in tissue engineering strategies. Scaffolds based on natural polymers such as collagen, chitosan, gelatine, alginate etc. offer a good opportunity to generate functional cartilage and bone. Due to their good biocompatibility, biodegradability and close resemblance to extracellular matrix (ECM) they have been extensively studied for cartilage and bone regeneration applications¹. However, poor mechanical properties and uncontrolled degradation limit their use. Organic-inorganic hybrid materials composed of interpenetrating networks of polymers and silica show good promise in terms of tailored biodegradation and toughness². In this work we present organic-inorganic hybrids of alginate and silica produced by sol-gel method through covalent coupling with 3-aminopropyltriethoxysilane and study their potential for tissue engineering application.

EXPERIMENTAL METHODS

Silica-alginate hybrids were prepared in aqueous media by reacting alginate with 3-aminopropyltriethoxysilane (APTES) using N-ethyl-N'-(3-(dimethylamino) propyl) carbodiimide (EDC) and N-hydroxysuccinimide (NHS). Hybrids were made with different coupling (C=1-5) and some of the samples were cross-linked by calcium ions. Formation of amide covalent bonding between the components was monitored by ATR-FTIR, ¹³C CP NMR and ¹⁵N NMR analysis and ²⁹Si MAS NMR was used to study the formation of silica network. Scaffolds were produced by freezing at -20°C and their mechanical behaviour, degradation and swelling (in Tris buffer pH=7.3) were studied. Degradation was followed by ICP-OES (for Si release), FTIR and DSC/TG analysis. MC3T3 osteoblast pre-cursor cells were seeded on the 3-D scaffold. Cell attachment was analysed by scanning electron microscopy (SEM) following 3 days of culture.

RESULTS AND DISCUSSION

The alginate readily reacted with APTES forming amide bonding (evidenced by FTIR, ¹³C CPNMR and ¹⁵N CP NMR). As the pH of the media was basic the hydrolysed ethoxy groups of APTES co-condensed and gelled, resulting in silica-alginate hydrogels (confirmed by ²⁹Si MAS NMR). Along with the amide bond formation, a side reaction yielding N-acylurea also occurred, which was difficult to avoid as the reaction was performed in aqueous solution. Degradation study in Tris solution showed that the weight loss depended on coupling and when the sample was double cross-

linked (by silica and calcium) degradation in time was retarded. Si dissolution profile indicated that as the coupling increased, silica release reduced in time. However the sample with C=1 showed faster silicon dissolution which could be due to the higher amount of unreacted APTES molecules. Swelling was also dependent on the coupling: sample with lower coupling with APTES showed higher swelling. When the hybrid was double cross-linked by silica and calcium ions, the swelling was additionally reduced (Fig 1).

Fig 1. Swelling behaviour

Fig 2. Stress/strain curves

The porous scaffolds had morphology typical for freeze-dried material with elongated pores having modal pore interconnect size ~ 150µm. All scaffolds regardless the coupling were elastic and flexible with stress/strain curves characteristic of a polymeric material (Fig. 2). Increasing the coupling degree slightly increased the stiffness however introduction of more silica (e.g. by co-condensation of APTES with TEOS) or additionally crosslinking with calcium increased the stiffness more substantially.

Cell attachment and distribution were evident. Individual and clusters of MC3T3 cells were seen and anchored to the scaffold surface by distinct filopodia.

CONCLUSION

Silica-alginate hybrids were produced with APTES using carbodiimide chemistry. Materials properties (degradation, swelling and compression strength) were influenced by the coupling with APTES and showed an improvement when hybrids were extra cross-linked with calcium ions. The porous scaffolds had elastic behaviour under compression indicating a potential for soft tissue application.

The Effects of Current Density on the Morphology, Electrochemical and Biological Characteristics of Poly(3,4ethylenedioxythiophene): Poly(styrenesulfonate) (PEDOT-PSS) Conducting Films

Catalina Vallejo-Giraldo¹, Abhay Pandit¹, Manus Jonathan Paul Biggs¹

¹ Network of Excellence for Functional Biomaterials (NFB), National University of Ireland, Galway
c.vallejogiraldo@nuigalway.ie

INTRODUCTION

Following implantation of a recording or stimulating neural electrode, glial scar formation at the electrode-tissue interface accelerates neural loss and increases electrical signal impedance, compromising the efficiency of the stimulating system¹. Studies with conducting polymers (CPs) as functional electrode coatings have shown to enhance tissue/electrode integration and electrode performance in situ through reduced impedance and the presentation of neurotropic moieties². Electrodeposition is routinely employed for the formation of poly(3,4ethylenedioxythiophene): poly(styrenesulfonate) (PEDOT:PSS) conducting polymer electrode coatings. However, electrodeposition parameters and their influence on the electrical, morphological, chemical and cytocompatibility properties of electrode films needs to be addressed.

EXPERIMENTAL METHODS

PEDOT:PSS polymeric films were electrodeposited on ITO glass via a three-electrode electrocell system at 0.4 mA/cm², 4 mA/cm², 43mA/cm² current densities, and characterized by four point probe analysis and EIS (conductivity), AFM (roughness, durability), SEM (morphology), XPS (chemical composition) and optical profilometry (thickness). Finally the cytocompatibility of the PEDOT:PSS films was evaluated by culturing SH-5YSY cells on electrodeposited PEDOT:PSS films by alamar blue™, live and dead assay and fluorescent microscopy for adherent cell counting and cell neuritic outgrowth and elongation

RESULTS AND DISCUSSION

PEDOT:PSS polymeric films demonstrated altered roughness, thickness and conducting profiles by altering the current density of film deposition (Fig 1, 2). Furthermore, cellular studies show that SH-SY5Y cells, are associated with a greater viability and proliferation rate on the films formed at different current densities used. (Fig 3). In addition, neurospecific differentiation was achieved as cells began to show neuritic outgrowth and cell elongation up to period of fourteen days in culture.

Fig 1. AFM roughness measurements of the PEDOT:PSS films over 10 μm². Film roughness varied with the different current density of

electrodeposition. (a) Control – Gold coated ITO Glass (b) 0.4 mA/cm² (c) 4 mA/cm² (d) 43mA/cm².

Fig 2. PEDOT:PSS films with different levels of conductivity were achieved by varying the current densities.

Fig.3. Fluorescent microscopy image of a film formed with the low current density (0.4 mA/cm²) showing a higher number of live cells present on the film. green= live cells, Red = dead

CONCLUSION

The topographical characterization showed that different levels of roughness can be obtained by varying the currents densities of film deposition. Furthermore, the films formed with current densities of 0.4 mA/cm² showed superior electrical performance compared to the higher currents densities evaluated in this work. The adhesion and proliferation of SH-5YSY cells on the surface of these films indicated the cytocompatibility of this material and no toxicity was detected. Thus, cell attachment was preferred on the PEDOT:PSS films formed using the low current density. Designing an optimized electrode coating material will require a trade-off between desired electrical, morphological, chemical and biological properties.

s.b.g.blanquer@utwente.nl

INTRODUCTION

Nowadays, it is commonly accepted that the origin of chronic back pain is often assigned to the degenerative conditions of the intervertebral disc (IVD) tissue. More particularly, disc degeneration mainly leads to tearing of the annulus fibrosus (AF) and extrusion of the nucleus pulposus (NP). The current surgical strategies are suboptimal, and reconstruction of the AF tissue by a tissue engineering strategy seems to be a better alternative. However, regeneration of the AF is challenging due to its complex and non-homogeneous structure. AF tissue consists mainly of highly organized collagen fibers with a specific orientation¹. Therefore the challenge of tissue regeneration is to design and prepare scaffolds that should reproduce the specific collagen fiber distribution of the native AF tissue as well as recover the native mechanical properties.

As a rapid prototyping process, stereolithography (SL) can generate 3D objects with high a diversity of structures and specific predetermined geometries, porosities and morphologies. Thus, complex structures with oriented pore channel architectures can be generated by this method. Using poly(trimethylene carbonate) (PTMC) as a rubber-like surface-eroding polymer, that is well-suited for the repair of soft tissue, biomimetic scaffolds were prepared and seeded with primary and stem cells to evaluate the cell proliferation and the extra-cellular matrix (ECM) production and orientation.

EXPERIMENTAL METHODS

The synthesis of the PTMC macromer was carried out by ring opening polymerization of TMC following by end-functionalization with methacrylate groups. A PTMC resin with suitable viscosity to allow building by SL (Mw of 5 kg/mol), was formulated. The resin contained propylene carbonate diluent, with 5 % wt of initiator and 0.15 % wt of Orasol® Orange dye. The scaffold was designed with the use of computer-aided design file and a 3D software (Rhinoceros 3D), and built in the SL apparatus (EnvisionTec Perfactory). The porosity, pore size and pore distribution were determined by μ CT. Tissue culture was performed with human annulus fibrosus cells (hAFCs) and human adipose stem cells (hASCs) using commercial medium and differentiation medium with TGF- β 3 respectively. The cell culture was analyzed in terms of cell proliferation, GAG/collagen production and collagen orientation.

RESULTS AND DISCUSSION

PTMC scaffolds were prepared by SL with a design of pore channels that mimic the specific fiber orientation of the native AF ranging from 30° to 45°

in the horizontal plan. The scaffolds were made with 80% of porosity and 450 μ m of pore size channel. Mechanical properties (compression modulus) of PTMC scaffolds were measured to be close to those of the native AF tissue (\approx 0.4 to 0.7 MPa). Both investigated types of cells were seeded into the PTMC scaffolds.

Figure 1: Collagen and GAG production of hAFCs and hASCs at 14 and 21 days of culture, A/Hydroxyproline assay; B/Sulphated GAG assay.

hASCs seeded in these PTMC scaffolds showed substantially higher production of collagen and GAG than hAFCs at both time points (Figure 1). In addition, the GAG:hydroxyproline production ratio of hASCs after 21 days was 1.7:1 similar to that of native AF tissue.

Figure 2: Visualization of collagen production in the PTMC scaffolds by picrosirius red staining, A/ hAFCs; B/ hASCs (scale bar 100 μ m).

The histological images after 21 days (Figure 2) showed that the scaffolds cultured with hASCs had pore channels filled with collagen fibers while the scaffolds cultured with hAFCs showed only limited collagen production. Polarised light imaging demonstrated that the produced collagen by hASCs formed remarkable fibers inside the pore channels.

CONCLUSION

Flexible and elastic scaffolds with oriented pore channel architectures were prepared by SL. hASCs produced collagen fibers in the biomimetic scaffolds that are comparable to those of the native AF tissue.

Development of Bioamine Cross-linked Gellan Gum Hydrogels as Soft Scaffolds for Neural Tissue Engineering

J. Koivisto^{1,2,4*}, Sh. Teymouri^{1,4}, J.E. Parraga^{1,4}, T.O. Ihalainen^{3,4}, K. Aalto-Setälä^{2,4}, M. Kellomäki^{1,4}

⁴ BioMediTech - Institute of Biosciences and Medical Technology, Finland, janne.t.koivisto@tut.fi

INTRODUCTION

Gellan gum (GG) is a potential hydrogel for many tissue engineering applications due to transparency, tuneable mechanical characteristics, and easy processing.¹ However, conventionally the crosslink is done with Ca^{2+} and K^{+} ions, but a high ion content will interfere with cell functionality in case of neurons or myocytes. Photo crosslinking can be done with GG-methacrylate modification, but that method can cause cytotoxic effects.²

We have crosslinked GG with positively charged endogenous bioamine, spermine (SPM), to avoid the aforementioned problems. The effect of laminin immobilization in the gel was evaluated in cell culture. The mechanical properties of these hydrogels were determined by compression testing and diffusion profile was established by fluorescence recovery after photobleaching (FRAP) method.³

EXPERIMENTAL METHODS

GG and SPM stock solutions were made in 10 % sucrose water solutions and sterilized by filtration. The basic hydrogel samples were made by mixing the GG and SPM at +37 °C.

The compression test was done for cylindrical samples, Ø 20 mm and height 7 mm, with Bose Biodynamic Electroforce 5100 in uniaxial unconfined compression at 10 mm/min rate. For FRAP measurements³ confocal microscope Zeiss LSM780 was used. As a diffusion agent, four sizes of dextran-FITC (20 kDa, 150 kDa, 500 kDa, 2000 kDa) mixed with the gel during gelation were used. For cell culture, laminin-1 was immobilized by mixing into the base components and gel was cast in 48-well plate. One hour after gelation the cells were plated on top of the gel. Neurosphere cells, obtained with the method described by Pomp et al. 2008⁴, were used in this study. Neurosphere attachment was monitored by light microscopy. The final cell culture results were studied with Live/Dead-staining with calcein-AM for live and ethidium-HD for dead cells.

RESULTS AND DISCUSSION

Ionic bioamine crosslinking method is suitable for making transparent gels, which are strong enough to hold their own weight. The Young's modulus is close to the modulus of soft tissue. The crosslinking process continues strongly after exposure to salts of basic cell culture medium. The change in compressive Young's modulus with one week incubation in cell culture medium in +37 °C is shown in Table 1.

Table 1. Compressive modulus of GG-hydrogels.

Hydrogel composition	Modulus (kPa)
GG + 0.6 % SPM	7.8 ±1.7
GG + 0.6 % SPM (1wk DMEM)	116.8 ±13.2
GG + 1.1 % SPM	23.7 ±2.5
GG + 1.1 % SPM (1wk DMEM)	158.5 ±16.3

The SPM concentration of GG has little effect on diffusion, as shown in Figure 1. The fluorescent dextran molecules diffuse almost freely inside the hydrogel. The larger molecules diffuse slower than smaller ones.

Figure 1. Diffusion profile by FRAP, fluorescence recovery is independent of cross-linker concentration.

Live/Dead-staining of neural cell cultures showed that the GG+laminin had significantly better cell survival than the non-laminin-GG, as shown in Figure 2. More and larger cell aggregates were attached than in non-laminin-GG. Future experiments are on the way to determine the effect of medium induced crosslinking.

Figure 2. Neurospheres on top of hydrogels, a) GG-1.1%SPM (no laminin), b) GG-1.1%SPM+laminin, c) GG-0.6%SPM+laminin.

CONCLUSION

The GG-SPM hydrogels are suitable for neural cell culture applications; however the cell culture medium affects the mechanical properties of the gel. The laminin-1 inside GG improved the attachment of cells.

INTRODUCTION

Rheology of ceramic pastes is of paramount relevance for both the development of injectable calcium phosphate cements for bone minimally invasive surgery and the fabrication of scaffolds by direct ink deposition or robocasting. This work assesses the thermoresponsive behaviour of self-setting calcium phosphate pastes prepared with a poloxamer hydrogel. Poloxamer hydrogels are known to have temperature-dependent rheological properties, i.e., their viscosity increases with temperature. The functionality of such pastes was evaluated, in terms of washout resistance in contact with liquids at physiological temperature, injectability and shape retention after injection. In addition, the hardening reaction of the pastes was studied either in simulated physiological conditions or in accelerated setting conditions by autoclaving.

EXPERIMENTAL METHODS

Coarse and fine alpha-tri-calcium phosphate (α -Ca₃(PO₄)₂, α -TCP) powders were obtained as described elsewhere¹. Solutions of poloxamer F127 (20 wt%) with and without accelerant (2.5 wt% Na₂HPO₄) were used as liquid phase. α -TCP was mixed with the liquid phase at liquid to powder (L/P) ratios of 0.35 and 0.5 mL/g. The extrusion behaviour was monitored at different paste temperatures (0, 7, 12, 15 or 20 °C) through injection tests¹. Paste cohesion was assessed injecting the pastes at different initial temperatures in Ringer's solution at 37 °C. Setting times were measured using Gilmore needles. Robocasted scaffolds were fabricated at room temperature using a customized robocasting device (Pastecaster, Fundacio CIM). The paste was dispensed with 250 μ m tapered tips following an orthogonal pattern to obtain cylinders of 6 mm \varnothing x 12 mm height with 45 % of theoretical macroporosity. Scaffolds were then set either by autoclaving (121 °C, 1 h) or by immersion in deionized water at 37 °C for 7 days. X-ray powder diffraction was performed after setting to quantify the crystalline phases present.

RESULTS AND DISCUSSION

The addition of poloxamer in the α -TCP paste avoided phase separation during injection and resulted in a temperature-dependent injectability: the injection force significantly decreased when the temperature of the paste decreased (Fig. 1a). The α -TCP/poloxamer extruded threads retained their shape when injected in Ringer's solution at 37 °C, irrespective to the initial temperature of the paste. The pastes with accelerant and L/P=0.35 mL/g were completely injectable through 1 mm cannula, and presented initial and final setting

times of 12 and 34 min respectively, and a compressive strength of 28.4 ± 5.1 MPa.

Fig. 1: a) Evolution of the injection force vs. paste temperature b) Needle shape crystals obtained with fine powder. c) Plate shape crystals obtained with coarse powder. d)&e) SEM micrographs showing the scaffolds architecture.

To fabricate robocasted scaffolds the L/P ratio was increased to 0.50 mL/g and no accelerant was used. Strand diameter matched the aperture size of the tip used for printing (250 μ m) and pore size was 200 μ m in the Z direction and 300 μ m in the X and Y directions (Fig. 1 d and e). α -TCP completely transformed into calcium deficient hydroxyapatite when the scaffolds were set in physiological conditions, whereas about 13 % of β -TCP was detected when they were autoclaved, due to the allotropic transformation of unreacted α -TCP. Different post-setting micro/nanostructures were obtained (i.e. needle- or plate-like crystals) depending on the initial particle size of the α -TCP powder used (Fig 1 b and c).

CONCLUSION

Totally injectable thermoresponsive self-setting calcium phosphate pastes presenting washout resistance, and clinically acceptable setting times and compressive strength were successfully produced. In addition to their potential application as injectable bone filler material, these pastes can be used for the fabrication of bone tissue engineering scaffolds by robocasting. Autoclaving is a fast processing route to consolidate the scaffolds. The combination of the self-setting α -TCP with thermoresponsive poloxamer hydrogel offers a versatile platform for bone regeneration, tissue engineering and drug delivery applications.

Cholecalciferol synthesized after UV-activation of 7-dehydrocholesterol onto titanium implants inhibits osteoclastogenesis in vitro

María Satué, Joana M. Ramis and Marta Monjo

Group of Cell Therapy and Tissue Engineering, Research Institute on Health Sciences (IUNICS), University of the Balearic Islands, Spain, maria.satue@uib.es

INTRODUCTION

UV-activated 7-DHC is a biocompatible coating for titanium implants in osteoblastic cells producing active vitamin D with positive effect on osteoblast differentiation [1]. The successful osseointegration of an implant is achieved by bone remodeling around the implant site what requires a balance between osteoblast and osteoclast to form new bone tissue in the peri-implant region. Since Ti implants covered with UV-irradiated 7-DHC promote osteoblast differentiation in vitro, we aimed at determining the effect of this bioactive coating on osteoclastic cells (RAW 264.7 cells).

Moreover, 7-DHC and its metabolites are very labile. In particular, 7-DHC is the most reactive lipid known to maintain a peroxidative free radical chain reaction. Thus, we also aimed at improving the UV-activated 7-DHC coating in two ways. First, by the addition of an antioxidant agent, α -tocopherol (VitE), as some studies prove that VitE protects bone from damage and suppresses bone loss [2]. Second, by controlling time and temperature incubation of the coating in order to improve the synthesis of D₃, since some studies confirm that the thermal isomerization to D₃ is time and temperature dependent [3].

EXPERIMENTAL METHODS

Machined titanium (Ti) surfaces were coated with 7DHC:VitE. Controls (EtOH, 7-DHC or VitE) were also included in the study. Surfaces were exposed to UV for 15 min and incubated at -20, 4 and 23°C for increasing incubation times: 0, 24, 48 and 96 hours. HPLC analyses were performed to determine the coating composition. For in vitro analysis, RAW264.7 cells were cultured for 5 days with RANKL addition. The in vitro response of RAW264.7 cells to coated Ti implants was determined in terms of cytotoxicity, gene expression of specific markers and immunostaining of actin ring and TRAP protein.

RESULTS AND DISCUSSION

The composition of the UV-activated 7-DHC coatings depended on the time, temperature and antioxidant addition. Indeed, the higher D₃ production was found after 48 hours of incubation at 23°C. VitE reduced the oxidation of 7-DHC in a dose-dependent manner, synthesizing more D₃ with the higher antioxidant dose (7-DHC:VitE 1:1; m:m).

Therefore, this best performing coating was tested in RAW264.7 cells. Results showed no cytotoxic effect and a significant decrease in the gene expression of key osteoclastic markers. Moreover, the immunostaining

confirmed the inhibition of both, osteoclastogenesis and TRAP protein expression.

Figure 1. (A) Effect of the different treatments on mRNA expression levels of *Trap* in RAW 264.7 dosed with RANKL for 5 days. Data were normalized to reference genes (Gapdh and 18S rRNA). Values represent the mean \pm SEM (N=6). Differences between groups were assessed by Student's t test: ^a p < 0.05 treatment versus control and ^b treatment versus 7-DHC. (B) Representative images (63x) of confocal laser scanning of RAW264.7 cell cultured for 5 days. Cells were stained with DAPI (stains nucleous; blue) and anti-Trap labelled with Cy3 (red).

CONCLUSION

The addition of vitamin E to 7-DHC coating before its UV activation, together with the control of temperature and time of incubation of the coating improves the synthesis of D₃. These results in a potent inhibition of osteoclastogenesis, suggesting a reduction on bone resorption activity. All in all, 7-DHC:VitE coated implants promotes osteoblast differentiation whilst inhibits osteoclast formation, suggesting a positive bone remodeling balance. This bioactive coating is here proposed as a new approach for implant therapies in patients with compromised bone health.

Mapping Phase Changes in Brushite Cements

A. Bannerman*, R.L. Williams and L.M. Grover

School of Chemical Engineering, University of Birmingham, UK

axb088@bham.ac.uk

INTRODUCTION

Brushite calcium phosphate cements have attracted interest as bone graft biomaterials due to their osteoconductive and resorbable properties¹. Degradation and bioactivity of the cement is highly dependent on the aqueous environment, and has been shown to vary significantly in the literature². Analysis of samples aged *in-vitro* and *in-situ* has largely used methods - such as scanning electron microscopy and x-ray diffraction - that give high resolution morphological, and/or overall bulk chemical information on the material at a given time point^{1,2}. These methods are often limited to the crystalline properties of the sample, and so can result in significant components or changes being unobserved.

In this study we aimed to fill the information gap of the current analytical methods, and provide further means to monitor cement degradation and help elucidate the bioactivity. Using confocal Raman microscopy (CRM) to map and quantify phase changes in brushite cement cylinders that were dynamically aged under physiological conditions in a range of media.

EXPERIMENTAL METHODS

Cylinder ageing: brushite cement cylinders (12x6mm) were produced from β -TCP and 3.5M orthophosphoric acid mixed at a ratio of 1.75g/ml and left to set overnight. Cylinders were sterilised under UV light then aged in 20ml of either phosphate buffered saline (PBS), Dulbecco's modified eagle medium, or fetal bovine serum, maintained at 37°C and changed every 24 hrs.

Image Mapping: cylinders were removed from media at staggered time points, dried, cut to expose the cross section and cryotomed to a smooth surface. Image mapping was performed using confocal Raman microscope with a 514nm 60mW laser. Observations were confirmed by XRD. **Computational analysis:** Data was exported to Matlab and baseline corrected. Clustering was performed to assign each pixel to the dominant phase of its' associated spectrum. Quantification was taken as a function of distance along the cylinder radius.

RESULTS AND DISCUSSION

Image mappings of PO_4 peaks associated with brushite and octacalcium phosphate (OCP) of cylinder cross sections showed evidence of a shell of OCP forming on samples aged in serum-free media. This study of the compositional evolution was taken further with a longer time series using PBS media that showed a clear development from an initially homogeneous distribution of brushite, to a three phase structure, as the outer layer of brushite underwent dissolution via hydrolysis, leaving a TCP scaffold that was subsequently seeded by OCP (Fig 1). Computational analysis to produce composite images of the dominant associated phase at each point is shown in Fig 2. Results support those in

Fig 1, showing a decrease in brushite leaving a β -TCP scaffold, with eventual seeding of OCP.

Figure 1: CRM mapping of brushite cylinder cross sections showing the PO_4 peak associated with brushite (A,B,C) and OCP (D,E,F) at 0 days (A,D), 10 days (B,E), and 30 days (C,F) ageing in PBS at 37°C. Scale bar 1000µm.

Figure 2: CRM mapping showing the dominant phase at each spatial location from Fig 1. (A) 0 days, (B) 10 days, and (C) 34 days. Colour key: Green - brushite, blue TCP, red OCP.

The results of this study have shown that phase changes inside the cement as a result of ageing in different media, are spatially detectable and quantifiable through CRM. This provides a complementary addition to the currently used imaging and analysis modalities, by providing spatial chemical information that is not dependent on the quantity of crystalline material in the sample. Such information may allow a significant insight into the degradation of implants, enabling improved material optimisation.

CONCLUSION

This study has shown that high resolution chemical mapping of calcium phosphate cements can be used to visualise and quantify chemical changes resulting from ageing under physiological conditions.

INTRODUCTION

Future tissue engineering developments rely on cell-instructive scaffolds. Cell fate could be driven by physico-chemical information coded within the biomaterial. Calcium phosphate materials (CaP) are widely studied for bone regeneration because of their biocompatibility and their chemical structure close to bone mineral phase¹. Nevertheless, most studied CaP lack osteogenic potential that could induce stem cells differentiation into mature bone cell phenotype.

We report spraying technique of calcium and phosphate solutions to elaborate CaP that induce human umbilical cord Wharton's jelly stem cells (WJ-SCs) to form *in vitro* bone nodules without the use of osteoinducer supplements.

EXPERIMENTAL METHODS

An automated spraying device was used for deposition of calcium phosphate. 0.2 M $\text{NH}_4\text{H}_2\text{PO}_4$ solution at pH 10 and 0.3 M $\text{Ca}(\text{NO}_3)_2$ solution at pH 4 were sprayed simultaneously 50 times then rinsed with MilliQ water and dried. Physicochemical characterization of CaP was investigated by Scanning Electron Microscopy (SEM) and Fourier Transformed Infrared Spectroscopy (FTIR). Osteoblastic differentiation of WJ-SCs was investigated at genic and proteic levels after 7, 14 and 21 days of culture.

RESULTS AND DISCUSSION

Spraying calcium solution simultaneously with phosphate solution leads to creation of a white mineral phase. SEM observations revealed granular morphology with micro-sized particles. FTIR spectras showed peaks within $500\text{--}1100\text{ cm}^{-1}$ and $3400\text{--}3600\text{ cm}^{-1}$ regions revealing octacalcium phosphate phase.

With no use of osteoinducer supplements, WJ-SCs were seeded on the sprayed CaP. DNA quantification after 7, 14 and 21 days highlighted a cell proliferation on the sprayed substrate. SEM observation showed cuboidal cells which were organized into 3D structures after a week of culture whereas cells cultivated on glass kept their fibroblastic morphology (Figure 1).

Immunolabelling of the formed colonies revealed membranous localization of integrins $\beta 1$ and $\alpha 2$. These colonies, positive for alkaline phosphatase

activity, are heightened within time of culture (Figure 2)

Figure 1: WJ-SC behaviour on sprayed CaP observed by SEM. **a:** Colony of cells with cuboidal morphology at day 7. **b:** Colonies are being heightened at day 14. **c:** Morphology of bone nodule at day 21. **d, e, f:** show cells seeded on untreated cover glasses at respectively 7, 14 and 21 days. (Scale bars = 100 μm).

Figure 2: Alkaline phosphatase activity of WJ-SC at day 14 seeded on **a:** glass, **b:** CaP, note the presence of positive cells only at the nodule localization. (Scale bars = 50 μm).

CONCLUSION

Spraying calcium and phosphate solutions allows the buildup of osteoinductive CaP. Without the use of osteogenic medium, WJ-SCs cultivated on CaP form bone nodules, which are considered as a model of osteoblastic differentiation². Our aim is to study the extracellular matrix formed within these bone nodules.

INTRODUCTION

The gradual aging of the population results in an increased incidence of osteoporotic bone fractures. In a good quality bone, the success rate for fixation with consolidation screws is acceptable, but in osteoporotic bone fractures, in which consolidation delays and other complications are common, failure rates for fixation using screws raises up to 25%.

The aim of this project is to check the ability of fibronectin (Fn) adsorbed on hydroxyapatite (OHAp) to enhance the osseointegration of devices used in the reduction of osteoporotic fractures and thereby reduce the morbidity of them

EXPERIMENTAL METHODS

Hydroxyapatite (OHAp) have been prepared by reaction of $\text{Ca}(\text{OH})_2$ with H_3PO_4 at pH 9.4. Powders were washed, freeze dried, and ball milled for 24 hours. Fibronectin (FN) from Human plasma was purchased from Sigma. The ceramic powders was characterized by ATR-FTIR, X-Ray Diffraction (XRD), Thermogravimetric Analysis (TGA), Scanning and Transmission Electronic Microscopy (SEM), specific surface area (SSA), particle Size Analysis, Helium Picnometry, Contact Angle, Z potential and Nuclear Magnetic Resonance ($^1\text{H-NMR}$) techniques.

Adsorption of Fn on OHAp was assayed by mixing 10 mg of the apatite with 1.5 mL of Fn dissolved in PBS Buffer at pH 7[1]. Protein binding was studied with a UV/VIS Spectrometer Lambda 16, by Raman spectroscopy in a Renishaw spectrometer and a Quartz-Crystal Microbalance with dissipation (QCM-D) in a KSV Instruments QCM-z500.

The “in vivo” study was performed using cancellous bone screws (4mm x 14mm) implanted in an osteoporotic rabbit model. One group supplemented with Fn adsorbed on hydroxyapatite, a second group supplemented with hydroxyapatite and a control group free of supplementary material. 42 adult female rabbits (16-18 months) of 4-5kg (White New Zealand) were used. Trabecular bone morphometry was analyzed with a Micro- CT eXplore Locus SP provided by GE Healthcare. The following parameters were studied: BVF (Ratio of the segmented bone volume to the total volume of the region of interest (%) mg/mm^3), BMD (Bone mineral density, mg/cc), (TbTh, (trabecular thickness, mm), and TbSp (trabecular separation, mm). The Stevenel’s blue bone stain was used for histological analysis.

RESULTS AND DISCUSSION

Hydroxyapatite samples with a 97% crystallinity, 34 m^2/g specific surface area and 858 Å crystal size were selected to perform the Fn adsorption experiments. Fn is active only when the RGD domains of the N-terminal are accessible. From the dissipation energy analysis from the QCM-D experiments, it can be deduced that Fn have been adsorbed in the active form.

Obtained basal levels of BMD (336 mg/cc) are below normal bone values and it confirms the osteoporotic condition achieved for the specimens used in the vivo experiments.

Independent time analysis of samples, show no significant differences for BMD and BVF variables. However, the median is slightly higher for the variable BMD in the sample with Fn. Although no significant differences have been found, a trend is suggested for those variables that define the trabecular bone microarchitecture. TbTh median is greater (0.49/0.46/0.40) and TbSp median is lower (0.67/0.73/0.74) for specimens supplemented with Fn-OHAp than for the OHAp and the control groups.

Significant differences have been found in TbTh and TbTs analysis performed at different distances from the implanted osteosynthesis screw. p 0.012 has been obtained for a comparison between an area separated from the screw and an area adjacent to the screw for the TbTh in Fn-OHAp supplemented specimens and p 0.008 has been found for the TbSp parameter. A greater non inflammatory cellularity and connective tissue was observed after only 24 hours of implantation for the Fn-OHAp supplemented specimens in comparison with the OHAp supplemented and the control groups.

CONCLUSION

The conformation of Fn adsorbed on OHAp has been controlled to keep RGD domains available.

This combination of Fn and OHAp can be a route to reduce the healing time in osteoporotic fractures

Mineralization of phosphate prestructured gelatine – Bulk preparation and characterization as bone substitute

Benjamin Kruppke, Hartmut Worch and Thomas Hanke

Max Bergmann Center of Biomaterials, Institute of Materials Science, Technische Universität Dresden, Germany,
Benjamin.Kruppke@tu-dresden.de

INTRODUCTION

In vitro mimics of natural mineralization processes through integration of organic molecules with more or less strong template function has been a common subject of hard tissue research in recent years. Incorporation of non-collagenous proteins forming polymer induced liquid precursors into mineralization processes seems to be the most promising approach of biomineralization.¹ As against single ions and atoms used for crystal formation – organic molecules and mineral precursors use to restrict mineralization. Collagen in its denatured form (gelatine) is assumed to be able to restrict mineral formation itself. Therefore, prestructuring of gelatine with anions or cations and the following mineralization process initiated by adding counter ions was investigated regarding dental repair material by Kollmann *et al.*² Here, its transfer to bone substitutes as follows is presented.

EXPERIMENTAL METHODS

Preparation. Mineralization was performed as batch process. First, phosphate-prestructured (PPS) gelatine was produced. For this, a 0.6 % w/w gelatine suspension was mixed with 0.1 M Na₂HPO₄ solution in a volume ratio of 3:17. PPS-suspension was adjusted to pH 7.0. Aqueous cationic solutions (1 M) – CaCl₂·2H₂O or SrCl₂·6H₂O at pH 7.0 – were added to PPS-suspension at a rate of 2.5 mL/min. During the entire precipitation process, it has been stirred at 300 rpm. Thereafter, the milky suspension was centrifuged and lyophilized. Finally, the pellets were pulverized by a mixer mill. Precipitates were named PPGC and PPGS for phosphate-prestructured gelatine mineralized with calcium and strontium, respectively.

Characterization. Mineral precipitates were investigated using X-ray diffraction (XRD) and transmission as well as scanning electron microscopy (TEM/SEM). Amount of gelatine in the mineral precipitate was determined by loss-on-ignition (LOI). 200 mg mineral was heated to 1000 °C for 1 h. After cooling the differences to initial weights were determined and compared to precipitated mineral without gelatine. Biaxial strength was determined by ball-on-three-balls test.³ For that, 400 mg mineral was compressed (510 MPa) to a disk of 13 mm diameter and 1.5 mm height. Degradation was determined by static incubation of compacted mineral (100 mg, o. d. 5 mm, 510 MPa) in both 4 mL simulated body fluid (SBF) and 4 mL phosphate buffered saline (PBS). During degradation, pH, calcium and phosphate ion concentrations were determined after (1, 4, 8) h and (. Statistical analysis was performed using one-way ANOVA.

RESULTS AND DISCUSSION

Crystal structure and morphology of calcium and strontium precipitates differs substantially. XRD revealed

PPGC is mainly brushite and monetite. SEM showed typical platelet shaped crystals in a range of 10 µm to 80 µm width and submicrometer thickness. For strontium precipitates XRD revealed sharp peaks that could not be assigned. Morphology of PPGS can be described as foliated spherical particles according to SEM.

For both minerals TEM revealed a certain amount of gelatine within the particles as they started to melt during HRTEM investigations. It was determined by LOI to 5.7 % w/w for PPGC and 4.1% w/w for PPGS. Increasing the amount of gelatine in PPS-suspension by factor 5 leads to an increase of gelatine in PPGC to 22.7 % and in PPGS to 9.7 %. It suggests a saturation of gelatine inside the mineral. Gelatine bound within the mineral affected the mechanic stability as well. As the ball-on-three-balls test revealed, PPGC showed a biaxial strength of 150 % of the gelatine free samples. In contrast, density of 2.6 g/cm³ was almost identical.

Degradation of PPGC and PPGS was characterized by decrease of pH during incubation in PBS. The pH drop from 7.4 to 6.7 within 1 h was followed by an overall reduction to 6.2 during 7 days. Due to the higher buffer capacity of HEPES within SBF, here pH of 7.5 was constant during the mineral incubation. Release of phosphate ions was not detectable in PBS with a constant concentration of 3.5 mM. In SBF, concentration of phosphate ions was kept constant for PPGS (right below 1 mM) whereas PPGC caused a decrease of phosphate ions to 0.5 mM within 24 h of incubation followed by a release of phosphate passing 3.0 mM after 7 days. Calcium concentration in PBS drops from an initial release (1 h, 0.8 mM) within the first day to 0.4 mM, then increases to 0.7 mM during 7 days of incubation. In SBF, PPGC shows an initial release of calcium (5.3 mM) followed by constant decrease of calcium concentration to 1 mM after 7 days.

CONCLUSION

As hydroxyapatite (HAp) precipitates are well known for their high calcium binding capacity – inhibiting osteoblastic activity – PPGC and PPGS shows promising properties as mechanically loadable materials. Additionally in contrast to HAp, their time dependent degradation allows bone remodelling under release of physiological degradation products.

INTRODUCTION

Zirconia (ZrO₂) bioceramics are frequently used in high-load bearing orthopaedic and dental applications due to their high mechanical strength and good biocompatibility. Among these, the most studied and widely used is yttrium-stabilized zirconia (YSZ) with excellent resistance to crack propagation¹. On the other hand, magnesia-stabilized zirconia (MgSZ) does not experience phase transformation and it has been shown to better resist degradation *in vivo*². Both of these materials are bioinert and thus lack osseointegration, which is important for implant fixation. Improving the initial attachment of osteoblast precursor cells to orthopaedic implant surfaces may lead to improved bone integration of the implant and long-term stability. We therefore investigated whether introduction of pores in these biomaterials could result in strong and bioactive scaffolds³. We fabricated sintered YSZ and MgSZ ceramics of medium 50-60% porosities and investigated the biological response of MC3T3-E1 pre-osteoblasts on these materials.

EXPERIMENTAL METHODS

Ceramic samples fabrication: The porous zirconia ceramics were produced by sintering powders obtained by plasma-spray pyrolysis⁴. The samples were characterized with respect to porosity, pore size distribution and mechanical properties.

Biological response: Cell viability and proliferation were assessed by the PrestoBlue™ assay, as well as by fluorescence microscopy. Cellular adherence and morphology were observed by SEM. Levels of ALP activity were measured to assess osteoblast differentiation whereas collagen production and Alizarine Red S staining were used for the evaluation of the extracellular matrix⁵.

RESULTS AND DISCUSSION

The ceramic substrates had similar porosities; 50% and 57% for the YSZ and MgSZ respectively. Pore size distributions were bimodal with two maxima at 0.7 µm and 167 µm for YSZ and 1 µm and 144 µm for MgSZ. Young modulus values were 10±3 GPa for YSZ and 6±2 GPa for MgSZ, whereas compressive strength values were 210±30 MPa and 120±30 MPa for YSZ and MgSZ respectively. Pre-osteoblasts were able to adhere, and spread on both substrates but cell morphology was different (figure 1). Cell viability and proliferation rates

were higher on YSZ than MgSZ. However, after 10 days, both substrate surfaces including interconnected pores were completely covered with cells. Abundant extracellular matrix formation was observed by SEM and quantified by collagen levels. ALP activity was detected as early as 7 days. Comparison of matrix mineralization showed higher levels on MgSZ. Apparently, surface chemical differences between porous YSZ and MgSZ exerted a significant influence over pre-osteoblastic cell attachment, morphology, and their capacity for proliferation and differentiation.

Figure 1. Cell adhesion of MC3T3 cells cultured on YSZ (left) or MgSZ (right) for 1 day. Pre-osteoblasts appeared more flattened on YSZ and more branched on MgSZ.

CONCLUSION

Despite differences in cell morphology and early proliferation patterns, both ceramics show mechanical properties similar to cortical bone and good biological properties, suggesting their potential as scaffolding materials for bone regeneration.

INTRODUCTION

Titanium (Ti) is the most widely used material for bone substitution due to its biomechanical properties. However, in some cases the osseointegration is not achieved, ending with implant failure. Hence, modifications of Ti biomechanical properties are required. On one hand, the mechanical properties can be modified combining Ti with other ductile metals, generating Ti-based alloys¹. On the other hand, the use of several different extracellular matrix (ECM) proteins or ECM-derived peptides or protein fragments has demonstrated an improved cellular response².

The aim of this study was to compare the in vitro cellular response to different recombinant fibronectin fragments functionalized on a new Ti alloy based on the optimization of molecular orbital calculations of electronic structures³. Cell adhesion, proliferation and differentiation of rat mesenchymal stem cells were analyzed.

EXPERIMENTAL METHODS

The alloy was fabricated at Fort Wayne Metals Research Corp. (Fort Wayne, IN, USA). Bars of 10 mm diameter were obtained by vacuum arc melting and drop casting. The bar was vacuum-homogenized and annealed at 650°C. Characterization of the alloy was done analysing the microstructure, elastic modulus, corrosion resistance and superficial energy. Fibronectin Cell Attachment Site (CAS) and Heparin Binding II (HBII) domains were synthesized using recombinant protein methods. Linear and cyclic RGD were synthesized by solid phase synthesis. Plasma Fibronectin was used as control. Peptides, fragments and different fragments combinations were covalently bound to the alloy surface by APTES silanization. Adsorption was analysed by OWLS. Rat Mesenchymal Stems cells (rMSCs) were seeded on the functionalized alloy and adhesion (LDH quantification and immunofluorescence evaluation), proliferation (LDH quantification) and differentiation (ALP quantification) were evaluated after 4h and 7, 14 and 21 days.

RESULTS AND DISCUSSION

A Ti25Nb21Hf alloy mainly composed of β -phase grains was obtained. XRD and TEM results demonstrated a lower presence of martensite α' and martensite α'' phases. The alloy exhibited interesting material properties such as lower elastic modulus and higher corrosion resistance, higher surface free energy and higher zeta potential values compared to c.p. Ti and Ti6Al4V. Since the adsorption quantities of

recombinant fibronectin fragments were higher when they were covalently bounded with APTES, compared to physisorption, cellular analyses were done after silanization. Although there were no statistically significant differences in the number of adhered cells, cells were more spread when surfaces were functionalized with combinations of CAS and HB2, instead of CAS or HB2 alone. These combinations also exhibited higher proliferation rates. Noteworthy, the 70%CAS-30%HB2 showed highest amounts of ALP (Figure 1).

Figure 1. Differentiation of rMSCs on Ti25Nb21Hf functionalized with different fibronectin fragments (CAS, HB2 or combinations), adhesion peptides (linear or cyclic RGD) and whole fibronectin (FN).

CONCLUSION

The modification of Ti biomechanical properties using the combination of metal alloying and ECM recombinant fragments functionalization seems promising for bone substitution purposes. In vitro results suggested that combinations of CAS and HB2 recombinant fragments were better for cellular adhesion quality, proliferation and differentiation responses than single fragments, obtaining interesting results for 70%CAS-30%HB2 combination.

INTRODUCTION

Bone formation is a complex, tightly regulated process, influenced by biochemical and physical factors. To develop a vital bone tissue engineering construct, all of these individual components have to be taken into consideration to gain an *in vivo*-like stimulation of target cells.

While previous studies in tissue engineering were mostly focusing on the influence of single factors, the purpose of the present study was to combine biochemical and physical stimulation using an artificial extracellular matrix (aECM) and electrical fields. Last ones have been induced by a new apparatus, applying electrical fields by transformer-like coupling (TC)¹.

Fig. 1: Set-up for electrical stimulation of cells¹

This method allows a stimulation of cells with exclusive electrical fields, avoiding interfering side-effects which occur with previous systems [Figure 1].

EXPERIMENTAL METHODS

Human mesenchymal stem cells (MSCs) were seeded on non-coated or aECM-coated three-dimensional poly(caprolactone-co-lactide) scaffolds. The aECM are based on porcine skin collagen type I (coll) in combination with a mixture of chondroitinsulfate (CS) or chemically modified high-sulfated hyaluronan (sHya, average degree of sulfation ~3).

Cultivation was performed either in expansion medium or osteogenic differentiation medium (300 μ M ascorbic acid, 10 mM β -glycerophosphate and 10 nM dexamethasone) for up to 28 days. For electrical stimulation cells were exposed to rectangular pulses (7 ms, 0.36 V/m, 10 Hz) for a duration of 4 hours followed by a 4 hours break while controls were placed in identical chambers but with unpowered coils.

Proliferation of cells was determined by assessment of lactate dehydrogenase activity which has been correlated with cell number using a calibration curve of defined cell numbers. Osteogenic differentiation was evaluated by biochemical analysis (ALP-activity) and on gene-expression level (RUNX-2, ALP, OPN, OC).

Short term effects such as Ca^{2+} influx and cell orientation have been analyzed in a special designed microscope chamber allowing live cell imaging.

RESULTS AND DISCUSSION

Results showed that aECM containing sHya decrease proliferation and enhance osteogenic differentiation represented by increases in ALP activity and gene-expression of several bone-related proteins (RUNX-2, ALP, OPN). Stimulation with electrical fields alone does not influence cell proliferation, but enhances osteogenic differentiation if osteogenic supplements were provided, showing additive effects by the presence of sHya [Figure 2].

Fig. 2: Influence of selected coatings and electric fields on ALP activity of human MSCs

CONCLUSION

The results clearly show that microenvironment and physical environment in the form of electrical fields play a modulating role in human MSCs osteogenesis. Especially the combined treatment of cells exposed to coll/sHya coatings and electrical fields showed synergistic effects, so that this data provides fundamental information for a better understanding on bone regeneration, and thus support the future development of highly effective tissue engineered bone constructs.

INTRODUCTION

The geometry of a microenvironment has demonstrated to impact cell behavior and potentially contribute to stem cell fate decision. It has been shown that 2D substrate geometries have an impact on cell traction forces and differentiation¹. Moreover, recent studies have indicated that substrate curvature influences tissue growth and cellular organization^{2,3}. However, a deeper insight into the role of geometrical cues is needed for the design of 3D biomaterial environments fostering tissue regeneration, e.g. in bone. In this study, we produced 3D substrates with specific curvatures by stereolithography (SL) and investigated the role of 3D surface curvature on the migratory and differentiation behavior of human mesenchymal stromal cells (hMSCs), hypothesizing geometry-induced alterations via changes in cytoskeleton organization.

EXPERIMENTAL METHODS

Cell culture substrates were designed containing convex and concave spherical, cylindrical and catenoid structures with principal curvatures of 1/125, 1/175, 1/250 and 1/375 μm^{-1} . The substrates were produced by SL using a poly(trimethylene carbonate) (PTMC)-based resin⁴. Substrates were homogeneously seeded with fluorescently stained bone-marrow derived hMSCs and cell migration in maintenance medium was observed up to 24 hours using time lapse multiphoton microscopy. The migration paths of $n > 13$ cells per structure were tracked and mean migration speed was determined. Groups were compared by two-way ANOVA with Tukey multiple comparison post-test ($p < 0.05$ for statistically significance). Furthermore, immunohistological stainings for osteocalcin, Runx2, and F-actin were performed after 10 and 3 days of culture in osteogenic medium (OM) respectively.

RESULTS AND DISCUSSION

hMSCs showed good attachment and migration behaviour on the PTMC substrate. Significantly faster migration was observed on concave spherical surfaces than on flat and convex surfaces. Migration speed on convex spheres showed a decreasing curvature trend towards the value on the flat surface (Fig 1).

Immunohistology revealed higher levels of Runx2 and osteocalcin for hMSCs on convex spherical surfaces compared to concave and flat surfaces (Fig 2).

Interestingly, higher signals for F-actin were found on concave compared to convex surfaces indicating higher cytoskeletal tension. This is in contrast to a previous study where a higher cytoskeletal tension was shown to promote osteogenic differentiation¹. Focal adhesion organization is currently under evaluation as it might help to explain our observations on stem cell

differentiation and migration due to its fundamental role in cell mechanics and cell-substrate interaction⁵.

Fig 1. hMSC migration speed on a flat surface and on concave and convex spherical surfaces. Mean \pm standard error of the mean.

Fig 2. Immunohistological images of osteocalcin (green) in hMSCs on convex (A) and concave (B) spherical surface (1/175 μm^{-1}) after 10 days in OM (nuclei in blue, F-actin in red). Scale bar 100 μm . Dashed line highlights the spherical surface.

CONCLUSION

SL was proven to be suitable for the production of 3D substrates with specific geometrical features. Our results indicate that surface curvature is a relevant parameter in the control of hMSC migration and osteogenic differentiation. Further analysis of cells on cylindrical and catenoid structures will give insight on the influence of different curvatures in more complex geometries. Ultimately, the gained knowledge will help in the design of 3D scaffolds that promote specific cell behaviour (migration, differentiation) for improved tissue regeneration.

Zinc Oxide Nanorod Interaction with Rat Mesenchymal Stem Cells

Giada Graziana Genchi^{1*}, Antonella Rocca¹, Virgilio Mattoli¹, Barbara Mazzolai¹, and Gianni Ciofani¹

¹Istituto Italiano di Tecnologia, Center for Micro-BioRobotics @SSSA, Viale Rinaldo Piaggio 34, 56025 Pontedera, Italy
giada.genchi@iit.it

Smart nanomaterials hold great promise in the manipulation of mesenchymal stem cells, due to their ability to promote peculiar cell behaviours by changing their properties upon physical stimulation. Here, we propose a toxicological investigation of piezoelectric ZnO nanorods on rat mesenchymal stem cells, first determining an optimal concentration for further future investigations.

INTRODUCTION

Zinc oxide nanostructures are receiving great interest in the scientific community thanks to their unique and tunable physical and chemical properties¹. Nonetheless, many contrasting results can be found in the literature about interactions between ZnO nanoparticles and cells², therefore the biocompatibility of ZnO nanostructures is still highly debated in nanomedicine.³ Here, we report on an investigation of the viability and proliferation of rat mesenchymal stem cells exposed to increasing concentrations of ZnO nanorods (NRs). Our findings show non-toxic effects up to 10 µg/ml of nanoparticles in the cell culture medium, encouraging further studies on the exploitation of ZnO NRs for the stimulation of stem cells.

EXPERIMENTAL METHODS

ZnO nanorods (773980 Sigma, 50 nm x 300 nm) were dispersed in 1 mg/ml gum Arabic (G9752 Sigma) at a concentration of 1 mg/ml with a short sonication (30 min, 20 W) in a 2510 Branson sonicator. This allowed NR stabilization in physiological solution through a non-covalent coating. The obtained NR dispersions were characterized by scanning electron microscopy in a FEI Helios 600 Dual-Beam system.

Rat mesenchymal stem cells (SCR027 Millipore) were cultured in low glucose Dulbecco's modified Eagle's medium with 10% fetal bovine serum, 100 IU/ml penicillin, 100 µg/ml streptomycin and 2 mM L-glutamine. Cells were maintained at 37°C in a saturated humidity atmosphere containing 95% air / 5% CO₂. Cells were seeded at a density of 6000 cell/cm² in 48-well plates, and incubated for 3 and 6 days with 0 (as control), 2, 5, 10, and 20 µg/ml of ZnO NRs. Cell proliferation was evaluated in terms of metabolic activity through the WST-1 assay (2-(4-iodophenyl)-3-(4-nitrophenyl)-5-(2,4-disulfophenyl)-2H-tetrazolium monosodium salt, BioVision). At each time point, cultures were treated with 200 µl of culture medium + 20 µl of the pre-mix solution for further 2 h and, thereafter, absorbance was read at 450 nm with a microplate reader (Victor3 Perkin Elmer).

Moreover, cellular adhesion and cytoskeletal conformation were evaluated following a 24 h incubation with 10 µg/ml ZnO NRs. Cytoskeleton/focal adhesion staining Kit (FAK100 Millipore) was used for the fluorescent staining of f-actin and vinculin,

following standard immunocytochemistry procedures that included incubation with an anti-vinculin primary antibody (1:200 diluted in 10% goat serum, GS) followed by incubation with a FITC-secondary antibody (AP124F Millipore, 1:400 diluted in 10% GS), 100 µM TRITC-phalloidin, and 1 µM DAPI for nucleus counterstaining. Samples were finally observed with a laser scanning confocal microscope (C2s Nikon).

RESULTS AND DISCUSSION

SEM investigation of ZnO NRs in gum Arabic denoted well dispersed nanostructures, with lengths in the range of 200-500 nm and diameter of 50-100 nm (Figure 1a). A qualitative study of cytoskeletal f-actin and vinculin (Figure 1b) revealed no significant changes in terms of cell morphology, cytoskeleton conformation, and nucleus shape in cells incubated for 24 h with 10 µg/ml NRs with respect to the control cultures (not shown). Finally, proliferation of MSCs evaluated in terms of metabolic activity by WST-1 assay did not result statistically different from the control cultures at concentrations up to 10 µg/ml within 6 days of treatment (Figure 1c). However, a significant decrement of cell proliferation was found for a dose of 20 µg/ml NRs ($p < 0.01$; ANOVA followed by Bonferroni's *post-hoc* test).

Figure 1: SEM imaging of ZnO NRs (a); confocal imaging of f-actin, vinculin and nuclei (respectively in red, green and blue, b); and WST-1 assay results at different NR concentrations and time points.

CONCLUSION

Although preliminary, our findings demonstrate no toxic effects of ZnO nanorods on rat mesenchymal stem cells, and encourage further investigations on the interaction of these nanostructures and MSCs. Future studies will be focused on the effects of ZnO NRs on the differentiation of MSCs, and on the exploitation of ZnO piezoelectric properties for cell stimulation.

INTRODUCTION

The ability to reliably control stem cell fate would have a significant impact for tissue engineering and regenerative medicine.¹ Various surface engineering strategies (chemical and topographic) have been exploited to direct stem cells differentiation into their various lineages. In general, mesenchymal stem cells (MSCs) can differentiate into adipogenic, chondrogenic, and osteogenic paths by varying the physical and topological features while keeping the chemistry constant. Topographically patterned surfaces have proven to be an important modality for controlling MSC function.² If the underlying topographically patterned surface had the same chemistry cell adaptation processes would play a major role and this would be independent on the differences in adsorbed proteins.³ Therefore, being able to control the underlying chemistry and topography would allow for the development of purpose specific cell regulating cues. We have compared differing nanotopographies and chemistries to ascertain configurations that have purposeful impacts on MSC growth and differentiation. Our aim was to explore the effects not only the size of the topographic features but also to see whether the underlying chemistry of the feature is an important parameter.

EXPERIMENTAL METHODS

Cell-substrata interactions were studied by using MSCs cultured on polymer-demixed nanotopographies. The nanofabrication system employed involves demixing of two immiscible polymers. Samples were fabricated using combination of three polymers (PMMA, PLA, and PCL) at different blend compositions, to produce polymer-demixed thin films with varying nanotopographies. The samples were analysed in terms of the surface topography, chemistry and wettability of each sample. Two representative sets of samples were chosen: one with similar topographies and differing chemistries and one with varying topographies and similar chemistries. Adult human MSCs, obtained from Lonza UK were used for the biological analysis. Following MSC culture and seeding onto each sample, analysis of cell proliferation, morphology and differentiation by immunostaining (using osteocalcin, collagen II and adiponectin markers) was performed at 7, 14 and 28 days.

RESULTS AND DISCUSSION

Polymer-demixing produces random topographic features, which is in contrast to uniform topographies produced by lithographic techniques. This technique advantageous as it is cost effective and able to produce features on large surface areas. Polymer demixed thin films from PMMA, PLA and PCL were used to fabricate differing nanoisland/nanopit topographies were. The feature size was controlled as a function of

the total polymer concentration in the spin-casting solution.

To the best of our knowledge, this is the first time that cell proliferation, morphology and differentiation has been investigated on these polymer-demixed samples. The results confirm that both physical and chemical characteristics can influence cell behaviour, specifically in terms of proliferation and differentiation. Cell proliferation was similar on the different samples studied at 7, 14 and 28 days. The morphology of the samples showed a shift from a fibroblast-like MSC morphology at 7 days, to a much more spindle-like morphology by 28 days. The images for the PCL/PLA sample are shown in Figure 1. The PCL/PLA sample had the highest levels of osteocalcin and collagen II compared with the PMMA/PLA and PCL/PLA samples. Furthermore, the PCL/PMMA sample showed the lowest production of adiponectin compared with the other blends. Representative images for staining of these proteins on the PCL/PLA surface are given in Figure 2.

Figure 1: Phase contrast images of MSCs on PCL/PLA sample at (a) 7 days (b) 14 days and (c) 28 days.

Figure 2: Immunofluorescence staining for (a) osteocalcin (b) collagen II and (c) adiponectin on PCL/PLA surfaces

CONCLUSION

Cells not only prefer nanotopographies, but the underlying chemistry also plays a significant role on differentiation. Modulation of the scale and pattern of chemically and topographically structures surfaces may allow for control of selective stem cell function regulation.

Gel Aspiration-Ejection Fabricates Anisotropic Injectable Dense Collagen Gels with Controlled Microstructure for Regenerative Medicine

Showan N. Nazhat*, Neysan Kamranpour, Mark James-Bhasin, Amir K. Miri, Chiara E. Ghezzi and Benedetto Marelli

Department of Mining and Materials Engineering, McGill University, Canada. showan.nazhat@mcgill.ca

INTRODUCTION

Technological improvements in collagen gel fabrication are required to enable advances in the formation of physiologically relevant, cell seeded, injectable tissue-equivalent scaffolds for regenerative medicine. Strategies to modulate collagen gel fibrillar density (CFD) and meso-scale organization have been pursued to fabricate collagenous matrices with extracellular matrix-like features. Amongst others, the plastic compression (PC) technique fabricates dense collagen (DC) gels with CFDs ranging from 5 to 25 wt%; suitable in a range of tissues¹⁻⁴. However, PC does not allow for the formation of injectable anisotropic collagen gels. Indeed, the injection of collagen gels, and not of the soluble precursor solutions, is desired to effectively exert control over locally delivered cells.⁵ While cross-linking increases collagen gel mechanical properties and allows their extrusion through syringe needles, it compromises biocompatibility.

Herein, gel aspiration-ejection is presented to fabricate injectable dense collagen (I-DC) gels of anisotropically aligned nanofibrils, modulated CFDs, microstructure, and mechanical properties. I-DC maintained the viability and supported the accelerated osteoblastic differentiation seeded mice mesenchymal stem cells (m-MSCs).

EXPERIMENTAL METHODS

FDA approved tools were uniquely assembled to produce I-DC via gel aspiration-ejection (Fig. 1i). In brief, the core of the system is a manually operated pump (e.g., Angioplasty Inflation Device) used to generate a pressure differential and force the collagen gel into, and subsequently out of, densification needles of defined gauge sizes. Pre-fabricated highly-hydrated collagen gels were aspirated into the needles by applying negative pressure in the pump, resulting in gel fluid expulsion outside of the needle. Subsequent application of positive pressure in the pump, controllably ejected I-DC; aided by the introduction of a buffered solution within the pump chamber. I-DC CFD ranged from <5 to >30 wt% depending on needle gauge size.⁶

I-DC gels were characterised by scanning electron microscopy (SEM) (Fig. 1ii), non-linear laser scanning microscopy and tensile mechanical testing.

Fig. 1 I-DC production. (i) Left to right, interchangeable inflatable Vertebral Augmentation System needles, two luer-lock valves connected in series, a syringe and an Angioplasty Inflation Device. (ii) Image of I-DC gel (scale bar 4 cm). Inset, SEM micrograph showing collagen fibril alignment (scale bar 500 nm).

For m-MSC-seeded I-DC, murine MSCs (C57BL/6 mice, GIBCO) at 80% confluency were passaged and seeded at a density of 2×10^5 cells/mL pre gelling and densification. m-MSC seeded I-DC or DC (produced through PC⁽¹⁾) gels were cultured for up to 21 days. Osteogenic supplements consisted of 50 μ g/mL ascorbic acid, 50 mM β -glycerophosphate, and 1 μ M dexamethasone, with replenishment every 3 days. Seeded m-MSC viability, osteoblastic differentiation potential and mediated-mineralization of I-DC were investigated.

RESULTS AND DISCUSSION

There was an increase in I-DC CFD and corresponding extent of alignment with a decrease in needle gauge size. I-DC apparent modulus significantly increased with CFD ($p < 0.05$) (Fig. 2).

Fig. 2. I-DC CFD and apparent modulus. (i) CFD as a function of initial collagen concentration and gauge needle diameter. (ii) Apparent modulus (calculated from the linear phase of the tensile stress-strain curves) as a function of CFD.

m-MSC viability were maintained through gel aspiration-ejection, which induced preferential cell orientation (Fig. 3). Gene expression indicated that osteoblastic differentiation were accelerated in I-DC compared to DC (data not shown); increasing the extent of m-MDC-mediated-matrix mineralization.

Fig. 3. m-MSC function in I-DC gels at day 21 in osteogenic medium. (i) Von Kossa stained histological sections indicating mineralization (scale bar 500 μ m). (ii) Confocal microscopy of viable m-MSCs (scale bar 100 μ m). (iii) SEM micrographs demonstrating mineralization (scale bar 5 μ m). Inset scale bar: 1 μ m.

CONCLUSION

Gel aspiration-ejection fabricates I-DC gels with controlled microstructure and creates unique opportunities in tissue engineering and regenerative medicine.

Bone-like Apatite Deposition on Chemically Synthesized Collagen in Simulated Body Environment

Toshiki Miyazaki^{1*} Jin Furui¹ and Yuki Shirosaki²

INTRODUCTION

Natural bone consists of organic collagen fiber and inorganic hydroxyapatite. Organic-inorganic hybrids are therefore expected to have high biological compatibility and similar mechanical performance to the natural bone. In addition, the hybrids are also expected for scaffolds supporting the regeneration of the bone tissue.

In order to construct such a hybrid, biomimetic process using simulated body fluid (SBF) or more concentrated solution has been proposed. Several researches have been reported concerning apatite formation on natural collagen through the biomimetic process¹. However, the animal-derived collagens still leave a risk for containing pathogens.

Recently, chemically synthesized collagen with triple helix structure similar to natural one has been developed as a safe biomaterial². Basic structure of the chemically synthesized collagen is amino acid sequence of proline (Pro) – hydroxyproline (Hyp) – glycine (Gly). Although apatite formation on the chemically synthesized collagen has been previously examined, highly supersaturated condition such as 1.5SBF with ion concentration 1.5 times those of SBF is needed to achieve apatite formation³. We recently revealed that immobilization with polyglutamic acid on the synthesized collagen is effective for inducing the apatite formation even in SBF. However process of the immobilization is still complicated.

In the present study, we attempted simple treatment of oxidation and Ca²⁺ incorporation for inducing the apatite formation in SBF.

EXPERIMENTAL METHODS

Films of chemically synthesized collagen were prepared by dropping the collagen solution on a glass plate and drying at room temperature. Then the films were subjected to the oxidation treatment in phosphate buffer solution containing TEMPO, sodium hypochlorite and sodium chlorite for 3 days. The films were then soaked in CaCl₂ solutions for 1 day and in SBF for 7 days. Surface structural changes were characterized by thin-film X-ray diffraction (TF-XRD) and scanning electron microscopic (SEM) observation.

RESULTS AND DISCUSSION

Figure 1 shows SEM photographs of the surfaces of synthetic collagen films without and with oxidation treatment, which were all treated with CaCl₂ and soaked in SBF for 7 days. Fine particles were observed for oxidized specimen, but not for non-oxidized one. The deposited particles were identified with low-crystalline apatite by TF-XRD.

The present results indicate that oxidation is effective for inducing the apatite formation. It is assumed that carbonyl groups are formed by oxidation of hydroxyl groups in hydroxyproline unit in the synthetic collagen. They would preferably attract Ca²⁺ and play a role in site for heterogeneous nucleation of the apatite.

Figure 1 SEM photographs of the surfaces of synthetic collagen films without and with oxidation treatment, which were all treated with CaCl₂ and soaked in SBF for 7 days.

Figure 2 TF-XRD patterns of the surfaces of synthetic collagen films without and with oxidation treatment, which were all treated with CaCl₂ and soaked in SBF for 7 days.

CONCLUSION

It was found that oxidation treatment in an aqueous solution was effective for providing the chemically synthesized collagen with ability of the apatite formation in SBF. This process is expected for novel fabrication process of synthetic collagen-apatite hybrids.

INTRODUCTION

The main advantage of having a material that degrades is so that an implant would not necessitate a second surgical event for removal. In addition, biodegradation may offer other advantages. For example, a fractured bone fixated with a rigid metallic implant may refracture upon removal of the implant. This is because the bone does not carry sufficient load during the healing process. However, an implant prepared from biodegradable materials could be engineered to degrade at a rate that would slowly transfer load to the healing bone [1,2].

Recently, fully resorbable composite bone repair plates comprising a PLA matrix reinforced with phosphate glass fibres (PGF) were investigated. The aim of the study was to determine their in vivo degradation characteristics in an animal model and the adaptive bone response at the site of implantation.

EXPERIMENTAL METHODS

Poly lactic acid (PLA, PURASORB®PLDL 8038, PURAC, Netherlands) was reinforced with 38 ± 5 vol% phosphate based glass (PBG) fibres of formulation: $40\text{P}_2\text{O}_5 - 16\text{CaO} - 24\text{MgO} - 11\text{Na}_2\text{O} - 4\text{Fe}_2\text{O}_3$ (in mol%). Composites were produced by stacking PLA sheets sandwiched with unidirectional and random fibre mats, and pressed at 210°C for 15 minutes at 38 bar. Implant plates were produced according to the dimensions in Fig. 1. and gamma sterilised. Metal plates were used as controls made from surgical grade stainless steel of the same dimensions.

New Zealand White rabbits underwent surgical application of either the composite or metal plate to the anteromedial aspect of the intact right tibia using conventional stainless steel screws. The rabbits were divided into equal groups and the time points from surgery to sacrifice were 2, 6, 12, 26 and 52 weeks. Radiographs of both tibiae were taken immediately after surgery and at sacrifice. Retrieved tibiae from three of the five rabbits at each time point were subjected to flexural testing of the combined bone-plate construct with respect to the opposite unplated control tibia. Cortical thickness was analysed quantitatively using Nano CT imaging (composite only) and Scanning Electron Microscopy (SEM) of resin embedded axial slices of the bone-plate construct.

RESULTS AND DISCUSSION

No evidence of macroscopic inflammation at any time point of retrieval for the composite plates was observed. Bone formation was observed at the periphery of the plate and around the screws (Fig. 2.).

Fig. 2. Bone growth around the periphery of the plate at (a) 2, (b) 6, (c) 12 and (d) 26 weeks.

The mechanical properties showed a gradual decrease in properties of the composite plate itself at a rate at which the bone was able to adapt effectively. The metal plated bone properties showed a different trend; an increase to a peak followed by a decrease at later time points. SEM results revealed thinning of the cortex under the metal plate at later time points, which may be responsible for this decrease (Fig. 3). Despite the loss, the flexural biomechanical properties of the bone-plate construct remained higher than the control.

Fig. 3. 26 week X-rays revealed thinning of cortex under metal plate (bottom) but not for composite plate).

Nano CT analysis supported the X-ray and SEM findings in the composite plates.

Conclusions

The properties of the composite plate-bone construct were consistent for the period of the study, despite changes in bone density over the period. The metal-bone construct reached a peak before decreasing, with apparent loss of cortical thickness underneath the plate.

INTRODUCTION

There is currently a huge unmet need for suitable bone adhesives in trauma surgery¹. Emerging synthetic adhesive technologies using modified native chemical ligation (NCL) hydrogels offer an innovative biomimetic approach to repair soft tissue². This hydrogel system uses poly(ethylene glycol) (PEG) precursors that avail of both thioester and amide moieties to crosslink the polymer network with no cytotoxicity issues, as validated by the subcutaneous implantation of these gels in a mouse model. We have used these chemistries as a platform to develop a system that incorporates biosilica into the polymer network, to improve its mechanical and osteogenic properties for hard tissue repair. The therapeutic benefit of siliceous additives in bone cements (e.g. Apatech's Activase Shape™) and bone fillers (PerioGlas® 45S5) are gaining significant clinical interest in orthopaedics. The target application of this system in the first instance is fixation of bone fragments that are too small to be attached by conventional fasteners.

EXPERIMENTAL METHODS

PEG(NCL) hydrogels were prepared as per method described by Strehin *et al.*,². Biosilica was isolated from *Cyclotella meneghiniana* a unicellular microalgae that was sourced from the Mississippi River, USA. Silanisation chemistry was used to modify the surface of *C. meneghiniana* with amine (–NH₂) and thiol (–SH) terminated silanes. The biosilica was then incorporated into the PEG(NCL) hydrogel system. Outcome measures include surface analysis using XPS, compression testing to determine modulus of gels and cell viability using neutral red.

RESULTS AND DISCUSSION

XPS results (Table 1) confirm that functional groups (–SH and –NH₂) were successfully grafted onto the surface of *C. meneghiniana*.

Peak	Peak position binding energy (eV)	Atomic Concentration (%)		
		Unmodified	Modified AMINE	Modified THIOL
Si 2P	102.84	21.01 (±0.05)	11.40 (±0.65)	14.60 (±1.01)
O 1P	532.21	43.28 (±0.12)	30.24 (±0.74)	33.02 (±1.43)
N 1s	399.64	3.35 (±0.84)	11.01 (±0.34)	3.27 (±0.77)
S 2P	162.91	Nil	Nil	5.92 (±2.02)
C 1s	284.42	32.39 (±0.12)	47.58 (±0.44)	42.02 (±1.29)

Table 1: XPS Atomic Concentration data of *C. meneghiniana*

An increase in carbon concentration from 32.29 to 47.58 and 42.02% in functionalised *C. meneghiniana* is likely to be a result of the carbon chains in the silane linkers. The increase in the atomic concentration of sulphur from 0 to 5.92(±2.02)% in the –SH modified

sample and increase in nitrogen from 3.35(±.84) to 11.01(±.34)% –NH₂ modified sample indicates a successful silanisation reaction.

The addition of biosilica and biosilica modified with –SH and –NH₂ end groups showed improved mechanical properties. For example, the young's modulus increased from 132.7kPa (hydrogels only) to 189.7kPa (with unmodified Si) and 287.3kPa (Si modified –SH) after 24hrs. In addition, swell test data (Fig. 1) has shown hydrogels to swell to 16% their relative weight within the first 24hrs, before equilibrating to <3% of their original weight. Gelation times in these types of surgeries are important, as surgeons need to fix multiple fragments together. Our system was found to have a gelation time of <3 minutes when mixed at pH 7.4. No cytotoxicity was observed in either the bioSi-PEG(NCL) hydrogels, or biosilica fillers alone when tested *in vitro* in accordance's with ISO standards 10993-05

Fig 1: Swell Data of hydrogels with/without biosilica after 40 days in PBS at 37degC

CONCLUSION

Often the incorporation of an additional phase into hydrogels can disrupt the crosslinking network, causing excessive swelling and reduced strength. Our results have found no adverse effects to the addition of the biosilica phase. Preliminary cell results have found no toxicity with the use of natural biosilica. Work is ongoing to test the cytotoxicity and inflammatory response of the system *in vitro*.

Elucidating the Biological Role of Soluble Silicon in Early Bone Mineralisation

Gurpreet Birdi^{1*}, Richard M. Shelton², James Bowen¹, Pola Goldberg Oppenheimer¹ and Liam M. Grover¹

¹School of Chemical Engineering, University of Birmingham, UK

²School of Dentistry, University of Birmingham, UK

g.birdi@bham.ac.uk

INTRODUCTION

The role of silicon in bone biology has been famously reported by Carlisle (1974)¹ and Schwarz et al (1973)². They demonstrated that when the levels of silica in an animal's diet were decreased to a critical level, bone and cartilage deformation resulted. Silicon at 0.5wt% *in vivo* has been shown to be present within the active mineralising osteoid regions, that is, the sites undergoing active calcification. This suggested that silicon may play a key role in the metabolism and stabilisation of the connective tissue present in bone and cartilage although its effect on calcification may arise indirectly through its interaction with matrix components. *In vitro* studies carried out by Reffitt et al (2003) demonstrated that type 1 collagen synthesis in human osteoblast-like cells was enhanced in the presence of 10-20µM orthosilicic acid³. Here we examine the evidence for a possible biological mechanism of orthosilicic acid (OSA), the soluble form of silicon influencing early bone mineralisation specifically focusing on its effect on mineral deposition and collagen fibril formation.

EXPERIMENTAL METHODS

MC-3T3s were cultured in Dulbecco's Modified Eagles Medium (DMEM) supplemented with 10% FBS, 2.5% HEPES, 1% penicillin/streptomycin and 2.5% L-glutamine. DMEM containing 0, 5 and 20µg/ml OSA was added after overnight attachment of the MC-3T3 cells. Cell mineralisation was determined using Alizarin red staining (Sigma Aldrich, UK) and Von Kossa assay. Collagen fibril formation was examined using atomic force microscopy (AFM), whereby collagen gels were prepared with a 2:1 ratio of DMEM and NaOH and various concentrations of sodium metasilicate were added to the gel solution and the pH adjusted to 8.0-8.5 with NaOH. TEM analysis was carried out to evaluate *in vitro* mineralisation within collagen fibres.

RESULTS AND DISCUSSION

The effect of OSA on cell mineralisation was carried out using Alizarin red staining and the Von Kossa assay, which indicate calcium and phosphate deposition respectively.

Figure 1: Calcium (Red) and phosphate (Black) deposition in MC-3T3s treated with or without OSA.

Cells without OSA and those exposed to 5µg/ml, showed an increase in the deposition of mineral. Cells treated with 20µg/ml OSA, however, showed to inhibit cell

mineralisation (Figure 1) suggesting that initial mineralisation is OSA concentration dependent.

Figure 2: AFM images of collagen fibres produced in the presence of various concentrations of OSA.

The effect of collagen fibril formation *in vitro* was evaluated in the presence of various concentrations of OSA. Collagen gels made with 5-50µg/ml of OSA showed a more intricate network of fibers when compared to gels made without OSA (Figure 2). At higher concentration however, OSA led to the degradation of the gel, indicating that OSA in lower concentrations modifies the collagen fibril network, however, in supra-physiological concentrations fibril formation is inhibited. TEM demonstrated mineral deposition within the fibers when gels were incubated with 5µg/ml OSA for 21 days (Figure 3).

Figure 3: TEM images, illustrating *in vitro* mineralisation within collagen fibres in the presence of OSA (B). No mineralisation was seen in non-treated samples (A).

CONCLUSION

Here we have evaluated the effect of OSA on collagen fibril formation and *in vitro* mineralisation. Increasing OSA concentration results in the development of a complex collagen fibril network up to supraphysiological OSA concentrations when the fibril network becomes fragmented. TEM images demonstrate that 5µg/ml OSA aids in mineral deposition within collagen fibers.

Innovation and Product Development – Example of a leading medical device company

Yves Bayon, Michel Thérin

Covidien – Sofradim Production
michel.therin@covidien.com

Ideas and innovating concept proposals of medical devices are most often the starting point of any new product development projects. They may originate from any company employees or are submitted by external third parties. They are evaluated by a series of internal processes, more or less exclusive, but should fit a number of prerequisites as suggested by the following questions:

Do they align with the current priority of the company, in terms of new product development?

Do these proposals address specific unmet clinical needs which may improve the quality of life of patients and/or facilitate the treatment of patients by the medical staff?

What is the maturity and complexity level of the technology behind ideas / concepts? What are the overall project cost and the project timeline from the concept to the launch phase (time considerations beyond of the technical development of the new product: handoffs, funding, regulatory, clinical, marketing...)?

What would the adoption by clinical users – and/or patients be? Preliminary Voice of Customers (VOC) and Voice of Technology (VOT) should be carried out. Very early, ideas / concepts should be evaluated by clinical users such as surgeons (at least 5 from different countries), by submitting questionnaires and/or presenting prototypes.

What is the market potential? What is the net present value (NPV) and anticipated return on investment? The pricing strategy should more and more rely on health economics analysis for better acceptance of the products by users and/or better reimbursement.

What is the current status of the intellectual property (e.g. list of issued patents and patent applications; external vs internal intellectual property; freedom to operate)?

What is the regulatory environment, in Europe, the US, emerging countries such as China, India...?

What is the current product and under development project portfolio of the competition?

What are the company staff capabilities for the technical development of the ideas / concepts, but also for their clinical evaluation, manufacturing, marketing, sales...? The last point is extremely critical. The company may have at the end a great device, but will make no money from it since it does not have the appropriate sales channels.

What is the risk of executing the translation of ideas/concepts vs not executing it?

The first selection stages of ideas / concepts are generally quite informal with short circuits decision, at a Director / Vice-President level.

At the end of the first evaluation round, the idea or concept should not stay as simple abstract ideas. Preliminary technical and performance proofs of concept should be brought for selection as a New Product Development (NPD) project. This is commonly carried out during the pre-concept phase for any new internal initiatives with limited available budget. Additional funding may come from national (e.g. in France, ANR, FUI grants) and European subventions (e.g. H2020 grants). Any external third parties sharing proposals should reach a similar level of proof or even greater.

The transfer of ideas / new concepts into NPD projects is decided by the portfolio management team, composed of the leadership / senior leadership team members, representing the key functions of project development such as R&D, Medical Affairs, Marketing. The decision is not taken on the sole aspects of ideas / concepts, but essentially on its economic profitability for the company. Other criteria leverage the decision: mission, vision and culture, product mix strategy, fiscal “health” of the company, current portfolio and development progress of NPD.

Any selected NPD projects must then progress according to contracts and schedules, agreed with all stakeholders, with sufficient budget to bring the product to its commercialization, in the shortest possible time. Project reviews are planned after each phase, concept (proof of concept), feasibility (prototype selection), development (manufacturing process definition), qualification (safety and efficacy demonstration, process validation and regulatory filing) and launch (product branding and commercialization). Stop and go decisions are taken after the end of each phase. Intermediate reviews of projects can be planned according to the progress of projects.

Other innovation processes coexist in the company such as the funding of start-up / small companies for their innovation by corporate venture capital (VC).

The innovation and product development process will be illustrated by a couple of examples developed by the Trevoux site of Covidien (Sofradim Production), specialized in the development and manufacturing of commercial medical devices for hernia repair.

Launching and Building a Science-Based Business

Iain McDougall

Taragenyx, Caledonia House, Lawmoor Street, Glasgow, G5 0US, Scotland, iain@taragenyx.com

Despite the dire headlines, innovative new medtech businesses are still launching and venture capitalists are still investing in exciting new companies, even those at the early stage.

Iain McDougall CEO of 1-year old Orthopaedic biotech company Taragenyx explains what it's really like to be an early-stage entrepreneur in today's start-up world at the intersection of medicine and technology.

A fascinating and informative walk through launching and building science based business, Iain discusses:

- Getting started - some science, a patent, and a couple of crazy founders
- Getting invested - 24 hours and \$2million
- Getting hired - building an A+ team when you can't actually afford them
- Getting Customers - convincing people your technology might actually change the world

Getting through - life on the entrepreneurial roller coaster. It's not what you think..

Iain McDougall is a serial medicine and technology entrepreneur with demonstrated success of founding, developing and restructuring businesses through major value inflexion points. Currently founder and CEO of Taragenyx, a venture funded orthopaedic biotechnology company developing bio-regenerative implants for the orthopaedic, dental, and general surgery markets. Prior to his venture activities Iain was partner-track engagement manager with one of the world's top-tier global strategy consulting firms. Utilising his core strengths in execution strategy, market development and virtuoso team leadership, he specialised in building and leading high impact teams to accelerate complex technology ventures delivering high value opportunities.

INTRODUCTION

Chitosan (CHT) is a linear polysaccharide derived from the deacetylation of chitin. The biocompatibility, biodegradability, antibacterial activity, non-toxicity and cellular compatibility of chitosan have attracted the scientific research interest in the latest two decades for its use in biomedical applications¹. Nevertheless, the mechanical properties of chitosan in the hydrogel form can be insufficient for many applications. Thus, reinforcement with a stiff inorganic phase appears as an appealing strategy to prepare chitosan hybrids with enhanced mechanical properties. In this work, chitosan-silica hybrids were produced using sol-gel reactions for the synthesis of the inorganic network. Tetraethylorthosilicate (TEOS) and 3-glycidoxypopyl trimethoxysilane (GPTMS) were used as the silica precursors. GPTMS served also as the coupling agent between the free amino groups of chitosan and the silica network. The morphology, swelling ability and the thermal properties of the hybrids were studied using various techniques. The cytotoxicity of the hybrids was also assessed.

EXPERIMENTAL METHODS

Chitosan-silica hybrids were produced by employing sol-gel reactions using TEOS and GPTMS as the silica precursors. The GPTMS to TEOS percentage was kept constant and equal to three while varying the GPTMS/TEOS molar ratio with respect to chitosan. The primary CHT solution consisted of 1.5% chitosan dissolved in 1% acetic acid. Then GPTMS was added and left for stirring for 16h. TEOS was prehydrolyzed in aqueous solution using HCl as catalyst and added in the CHT/GPTMS solution. After 1h of stirring the solution was placed in petri dishes. The hybrid membranes were aged for 1 week at room temperature and then for 5 days at 50°C. Furthermore, pure CHT, pure GPTMS, CHT-GPTMS and GPTMS/TEOS films were prepared for comparison.

RESULTS AND DISCUSSION

The morphology of the hybrids was studied by a scanning electron microscope (SEM) equipped with energy-dispersive X-ray spectroscopy analysis. The results revealed the uniform distribution of the inorganic phase.

The influence of the incorporation of the inorganic phase was assessed by swelling measurements into water using gravimetric techniques providing also valuable information regarding the structure of the prepared hybrids. The swelling ability is suppressed by

the addition of GPTMS providing evidence of its crosslinking behaviour.

The thermal degradation of the hybrids was studied using thermogravimetric analysis (TGA) and the thermal transitions were followed by differential scanning calorimetry (DSC). A glass transition was observed below room temperature for the hybrids with higher GPTMS content and was attributed to the presence of a distinct GPTMS phase. The latter transition was further studied together with the dielectric relaxations of chitosan by employing dielectric relaxation spectroscopy (DRS) in a wide temperature and frequency range having characteristics of a primary dielectric mechanism.

Previous studies using nuclear magnetic resonance (NMR) have shown that the epoxy ring of GPTMS is opened and linked to the amino groups of chitosan at a yield of 20%². In this work the segmental motion of polymerized GPTMS phase in the prepared hybrids was probed and compared to pure GPTMS and GPTMS/TEOS samples showing that excess of GPTMS leads to the formation of a distinct GPTMS phase.

Finally, the cytotoxicity assay showed that the prepared hybrids are not cytotoxic irrespectively of the GPTMS content. The prepared materials could be used for the reinforcement of already prepared scaffolds using novel strategies proposed by our group that lead to porous structures with two co-continuous phases³.

CONCLUSION

Chitosan-silica hybrids were prepared using sol-gel reactions for the synthesis of the inorganic phase. GPTMS served as a crosslinker for the chitosan chains as well as the coupling agent between the inorganic and the organic phase. The physicochemical properties of the hybrids could be modified by varying the silica precursors content. The non-toxicity of the above hybrids makes them excellent candidates for their use for porous membranes fabrication or as a reinforcement of scaffolds for tissue engineering approaches.

INTRODUCTION

One of the main issues in tissue engineering (TE) is the fabrication of scaffolds that closely mimic the structural properties of the tissues to be regenerated. This is of pivotal importance in the case of graded tissues such as the bone-ligament interface. In this work, we propose the combination of electrospinning (ESP) [1] and 3D fiber deposition (3DF) techniques [2] to create triphasic scaffolds for the bone-ligament interface. By combining these techniques, poly-caprolactone (PCL) and poly lactic-co-glycolic acid (PLGA) based scaffolds with a graded variation of their physicochemical and mechanical properties were fabricated.

EXPERIMENTAL METHODS

Scaffolds were fabricated through a two-step process. Initially, PCL (average Mn ~45000) 3DF scaffolds were manufactured with a Bioscaffolder device (SysENG, Germany). The polymer was put in a stainless steel syringe and heated at $T = 100\text{ }^{\circ}\text{C}$. A nitrogen pressure of 5 Bars was applied to the syringe through a pressurized cap when the molten phase was achieved. The fiber diameter d_1 , the fiber spacing d_2 , the layer thickness d_3 and the number of deposited layers were set at 250 μm , 700 μm , 150 μm and 4, respectively. The scaffold architecture was determined by a 0-90 layer configuration where fibers were deposited with 90° orientation steps between successive layers. The plotting speed was changed within 275–325 mm/min. The PCL 3DF scaffolds were partially covered with a paper foil, fixed on a PDMS and positioned under an ESP jet. An aligned electrospun fibrous network was fabricated from a 4% (w/v) PLGA solution in 1,1,1,3,3,3-hexafluoro-2-propanol (HFIP). The voltage was 20 kV, the air gap was 20 cm, the flow rate was 1 ml/h, and the needle used had a diameter of 0.8 mm. The ESP fiber density was determined as the time frame used during fabrication, which was set to 90 minutes. The porosity of 3DF scaffolds was calculated following a theoretical approach [2]:

$$P = 1 - \frac{\rho}{4} \cdot \frac{d_1^2}{d_2 \cdot d_3}$$

The porosity of ESP and mixed regions was experimentally measured by measuring the ratio between the apparent density of the scaffold and the specific density of the bulk material. Human mesenchymal stem cells (hMSCs) were seeded on the triphasic scaffolds at a density of 1.4×10^5 cells/cm² and their metabolic activity assessed after 1, 5 and 7 days. After 7 days in proliferation medium and 7 days in mineralization one, metabolic activity and alkaline phosphatase (ALP) staining were measured.

RESULTS AND DISCUSSION

The scaffolds were characterized by three different regions: the 3DF, the ESP and the mixed parts (Fig. 1a).

Fig. 1 – Triphasic scaffold structures

SEM analysis revealed a fiber diameter of $208 \pm 7.1\text{ }\mu\text{m}$, a fiber spacing of $734 \pm 15\text{ }\mu\text{m}$, and a layer thickness of $202 \pm 9\text{ }\mu\text{m}$ for the 3DF region (fig. 1b). The fiber diameter of the ESP network was $0.588 \pm 0.02\text{ }\mu\text{m}$ (fig.1c-d). This corresponded to a porosity of $77 \pm 1.7\%$ for the 3DF region, and to a porosity of $95.9 \pm 1.6\%$ for the ESP one. The porosity of the mixed region was measured as $68.9 \pm 3.1\%$. The scaffolds were interconnected porous structures and no layer delamination phenomenon occurred. An increase of the metabolic activity was measured within culturing time. A partitional analysis on the different areas of the triphasic scaffolds showed a similar trend after 7 days in differentiation medium. ALP staining showed a heterogeneous production of the protein in the scaffold, thus suggesting that our triphasic graded scaffold design may have potential for the regeneration of the bone-ligament interface.

CONCLUSION

The integration of ESP and 3DF represents a promising technique for the realization of scaffolds for interface TE applications, because it allows mimicking the structural biological environment through the combination of different biomaterials at different scales.

INTRODUCTION

Freeze-drying is a well-established technique for the fabrication of 3-dimensional (3D) porous collagen scaffolds [1]. Despite their excellent mechanical properties often these scaffolds do not recreate the elastic recoil of many tissues. Elastic fibers are key structural components of such tissues providing this recoil and resilience. We therefore explored the inclusion of elastin into porous 3D collagen scaffolds to impart flexibility to the resulting material. In addition to its mechanical properties elastin elicits biochemical responses such as cellular attachment, spreading, chemotaxis, proliferation and differentiation [2]. To elucidate the cellular cues that elastin could bestow on the resulting collagen-elastin composite scaffold we studied cell interactions with elastin.

EXPERIMENTAL METHODS

Scaffold preparation; Collagen +/- elastin (1%(w/v) total protein) was swollen in 0.05M acetic acid at 4°C overnight then homogenized. The suspensions were freeze-dried (VirTis adVantage benchtop (Biopharma Process Systems, UK)) at -0.9°C/min to a final temperature of -26°C for 4h. The ice phase was sublimed at 80mTorr, 0°C for 27h.

Scaffolds were chemically cross-linked with 1.150g EDC and 0.276g NHS per gram of scaffold in 75% v/v ethanol for 2h. The scaffolds were extensively washed with deionised water then freeze-dried.

Tensile testing; Rectangular sections with a cross sectional area of ~7x4mm were hydrated in deionised water for 1 h then extended at 6 mm min⁻¹ to failure. The Young's modulus (*E*), stress at 20% strain (σ), and failure strain were calculated from the stress-strain plot.

SEM; Cross-sections of scaffolds were mounted on stubs and sputtered with platinum then imaged with a JEOL-820 scanning electron microscope at 10 kV.

Tropoelastin constructs (fig. 2a) were expressed in the pET3d vector in *E. coli* BL21 (DE3) and purified by RP-HPLC.

Cell attachment analysis; Tissue culture wells were pre-coated with recombinant proteins then 2.5x10⁴ cells added for 45 min and the bound cells quantified.

RESULTS AND DISCUSSION

SEM showed that insoluble (IE) and soluble (SE) elastin were incorporated into the porous 3D structure of collagen based scaffolds (fig 1). Inclusion of IE and

Figure 1: SEM of Coll-IE (a) and Coll-SE (b). Bar=10μm

SE reduced the stiffness of the collagen-based scaffolds showing decreased stress at 20% strain and decreased Youngs modulus (table 1). Therefore these composites possess mechanics that resemble native elastic tissues such as skin (Youngs modulus=5-12kPa).

	Strain at failure	Stress (kPa)	Youngs modulus (kPa)
Coll	0.32±0.01	7.8±0.9	81±8
Coll-IE	0.33±0.03	4.5±0.8	45±9
Coll-SE	0.41±0.02	2.6±0.2	27±2

Table 1: Elastin reduces the stress and Youngs modulus of collagen-based scaffolds

The mechanism of cell adhesion to elastin was studied to determine the biochemical properties that elastin incorporation imparts to collagen scaffolds. Cells adhered to recombinant tropoelastin constructs with the following affinity WT>N18>N10 (fig. 2b). This identified 2 binding sites on elastin; 1) a site beyond domain 18 which is accounted for by the reported C-terminal RKRK cell-binding motif; 2) A novel site between domains 10 and 18. Integrin $\alpha_v\beta_5$ inhibition prevented cell binding to N18, identifying this as a cellular receptor for this region (fig 2c). Therefore elastin incorporation can impart 2 cell-binding sites to collagen scaffolds and cell-adhesion via a distinct mechanism compared to a pure collagen scaffold.

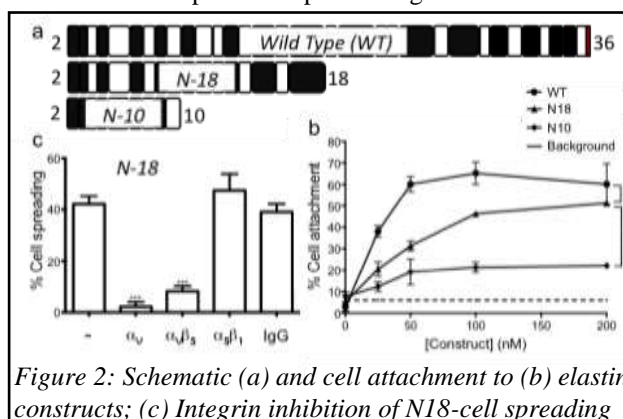

Figure 2: Schematic (a) and cell attachment to (b) elastin constructs; (c) Integrin inhibition of N18-cell spreading

CONCLUSION

Elastin reduces the stiffness of 3D collagen scaffolds and can bind to cells via integrin $\alpha_v\beta_5$.

INTRODUCTION

Peripheral nerve injuries have a high incidence in today's society¹⁾. Despite recent progress in peripheral nerve trauma management, recovery of functional parameters is usually far from normal and thus much attention is being paid to nerve regeneration research. In a previous study^{2,3)}, flexible and biodegradable chitosan- γ -glycidopropyltrimethoxysilane (GPTMS) hybrid membranes exhibited better cytocompatibility in terms of osteoblastic cells than chitosan membrane. Porous chitosan hybrid membranes, derived by freeze-drying the hybrid gels, showed that the cells were attached and proliferated both on the surface and into pores. In this study, new biodegradable nerve guides from these chitosan hybrids were prepared and their biocompatibility was examined for the nerve regeneration by using animal model.

EXPERIMENTAL METHODS

A total of 25 adult male Sasco Sprague rats (Charles River Laboratories, Barcelona, Spain) weighing approximately 250 g at the start of the experiment were used. In Group 1, animals recovered from axonotmesis sciatic injury without any other intervention (Crush). In Group 2, axonotmesis sciatic nerve was infiltrated with a suspension of 1 250-1 500 MSCs (total volume of 50 μ L) (CrushCell). In Group 3, axonotmesis lesion of 3 mm was wrapped with a porous chitosan hybrid membrane covered with a monolayer of non-differentiated human MSCs (CrushChCell) and in Group 4, axonotmesis lesion of 3 mm was wrapped with a porous chitosan hybrid membrane (CrushCh). A standard crush injury was performed by a non-serrated clamp, exerting a constant force of 54 N for a period of 30 seconds, 10 mm above the bifurcation into tibial and common peroneal nerves, inducing a 3 mm axonotmesis lesion. All animals were tested preoperatively (week 0), and every week until week 8 and then every two weeks until the end of the 12-week follow-up time. Motor performance and nociceptive function were evaluated by measuring extensor postural thrust (EPT) and withdrawal reflex latency (WRL), respectively.

RESULTS AND DISCUSSION

The withdrawal reflex latency (WRL) test was used to assess nociception. In the first 2 weeks post sciatic crush injury, the WRL response was absent (i.e. lack of withdrawal within 12 seconds; the cutoff time to prevent thermal damage to the paw) in a large majority of animals. With time, the WRL improved in all animals and at week 12, the WRL values were

2.00 \pm 0.00, 1.29 \pm 0.18, 1.17 \pm 0.17, and 3.3 \pm 0.54 seconds, in Crush, CrushCell, CrushChCell, and CrushCh, respectively. A significant difference was observed between the groups in WRL data with delayed recovery in WRL performance in CrushCh compared to the other three groups. The sciatic nerve crush caused severe muscle force deficit in the affected limb immediately post-surgery. At week 1, the percentage of motor function deficit for the right hindlimb reached over 90% in all groups. A gradual recovery of the right hindlimb extensor postural thrust occurred during the 12-week survival time in all groups, so that at week 12, the EPT deficit in the affected side, although not fully reestablished, was reduced to only 4.16 \pm 5.60, 2.79 \pm 0.41, 3.24 \pm 0.42, and 7.43 \pm 3.58 in Crush, CrushCell, CrushChCell and, CrushCh, respectively. EPT performance was similar in all groups, although at the end of the 12 weeks of recovery, the EPT values were lower in CrushCell and CrushChCell groups. Fiber regeneration was good in all experimental groups, though the regenerated nerves presented smaller myelin fibers than the normal nerves without injury. Myelinated fiber density and total number were significantly higher than in controls in all nerve regeneration groups except for the CrushCh group. Axon and fiber diameter and myelin thickness were significantly lower in the 3 experimental groups compared to control group (normal sciatic nerve without injury). Analysis of the inter-group variability among regenerated groups, showed that CrushCh group had significantly lower fiber density and fiber total number and a higher myelin thickness while no statistically significant differences were detectable for the remaining histomorphometrical predictors of nerve regeneration (fiber diameter and axon diameter).

CONCLUSION

The porous chitosan hybrid membranes alone may represent a very promising clinical tool in peripheral nerve reconstructive surgery. Thus, human umbilical cord human MSCs can be expanded in culture and induced to form several different types of cells. They may therefore in future experiments, be tested as a new source of cells for cell therapy, including targets such as peripheral nerve in more serious lesions (neurotmesis with and without loss of nerve tissue) and muscle.

Nano-spun Meshes as Scaffolds for Regeneration and Stiffness Remodelling of Pelvic Floor Soft Tissues

Mahshid Vashaghian¹, A. Ruiz Zapata², B. Zandie Doulabi³, T.H. Smit²

1. Obstetrics & Gynaecology, 2. Orthopedics, VU University Medical Center, Amsterdam, The Netherlands, 3. Oral cell biology, (ACTA), The Netherlands, M.vashaghian@vumc.nl

INTRODUCTION

In pelvic floor disorders, like pelvic organ prolapse, a mesh-like implant is used to restore the function of damaged tissues. Post-operational problems like erosion or adverse body response may happen which are directly a function of the mesh nature. Cell-based therapies are new disciplines for regeneration of the organs with the use of host cells and biomaterials as scaffolds for supporting cells in-growth. Electrospinning is a straightforward and inexpensive method for producing scaffolds with high surface area-to-volume ratio and ultra-thin fibrous structure. Owing to their architecture and isotropic orientation, non-woven meshes are well-known for their superior properties in resembling natural ECM, cellular adhesion and proliferation, therefore good candidates for regeneration of soft tissues as found in pelvic floor, for mesh-based surgical treatments.

AIM

To evaluate the potential of electrospun scaffolds for regeneration of soft pelvic tissues regarding biocompatibility, cell-scaffold interactions, matrix deposition, micro-structure, mechanical properties, and stiffness remodelling of the matrix.

EXPERIMENTAL METHODS

Polymeric solutions of PCL/gel 15% (70:30), PLGA/PCL 15% (75:25) and Nylon 20% were prepared in TFE, CHCl₃:MeOH and Formic Acid respectively. The solutions were electrospun horizontally into nanofibers and collected on aluminium foil (the processing conditions are not shown in the abstract version).

Meshes were vacuumed overnight, sterilized in 70% ethanol followed by another night incubation in 1% antibacterial medium. Human vaginal fibroblasts (Passage6) were seeded on sterile samples at a density of 150,000 cell/ cm² and cultured in DMEM supplemented with 10% FCS and 1% antibiotic. At days 1 and 3, 10 and 21 samples were collected for different characterizations. Live/dead staining of calcein AM and ethidium homodimer-1 was done for viability. Scanning electron microscopy (SEM) was used to characterize the micro-structure of the non-seeded meshes and cell-scaffold interactions. Histological analysis was performed on cryosectioned samples with H&E and PicoSirus Red staining. Meshes were evaluated for their isotropic micro-stiffness with indentation tests (Piuma, Optics11), with and without cells to monitor the changes of stiffness upon matrix deposition. De-ionized water drop was used to measure contact angel for hydrophilicity of the meshes.

RESULTS AND DISCUSSION

Live/Dead staining showed all the meshes are biocompatible (>95%, measured by number of live/total number of count), although viability was also dependent on hydrophilic creature of the meshes meaning that the more hydrophilic the mesh is like nylon, the more number of cells attach and therefore more viability is observed. Cells number increased from day 1 to day 3, stayed constant from day 3 to day 10 and increased again from day 10 to day 21.

This determines cells proliferated on all the meshes, and the most on Nylon, although the trend in cells increase was not constant all over the experiment.

SEM pictures, cells attach, elongate and spread all over the three meshes and grew into sheets from day 1 to day 21. Histological analysis confirmed the proliferation and matrix production on the meshes, although the infiltration of cells through the mesh thickness was low in all three (data not shown in here).

Material	PLGA/PCL	Nylon	PCL/gel
Fibers diameter	0.7-1.5 µm	100 nm	120-150 nm
Pore diameter µm	12-13	0.5-4	1-2.5
Porosity %	65	68	71.6
Thickness	60 µm	50-60 µm	70-80 µm
Indent stiffness (N/m)	24.9	20.3	16.75-19
Indent Y module (MPa)	2.3	0.86	1.1
Contact angel	120-130	45	70

Table1. Mesh characteristics

Figure1. Cell sheet on spun meshes at day 3 (rest of time points are not shown here) from left to right: Nylon, PCL/gel, PLGA/PCL.

Nano-indentation tests at different time points confirmed the deposition of matrix (soft areas as opposed to the cell-covered stiff areas) increasingly during 21 days of the experiment. This also confirmed the remodelling of the matrix by cells, replacing their surrounding from focal adhesions to prominent matrix proteins like collagen.

Figure2. PicoSirus red (staining for collagen) of meshes at day 3 (rest of time points are not shown here), from left to right: Nylon, PCL/gel, PLGA/PCL .

CONCLUSIONS AND FUTURE DIRECTIONS

Although non-woven electrospun scaffolds seem suitable for tissue engineering purposes, more of investigations are needed to have better insight into ECM deposition as well as mechano-biological responses on them.

Coating of polypropylene mesh with micro-structured gelatine as potential biomimetic composite for active hernia treatment

Selestina Gorgieva¹, Maja Kaisersberger Vincek¹ And Vanja Kokol^{1,2}

¹University of Maribor, Institute for Engineering Materials and Design, Smetanova ul. 17, SI-2000 Maribor, Slovenia
Presenting author: selestina.gorgieva@um.si

INTRODUCTION. Polypropylene mesh (PP_{mesh}) implants used in abdominal hernia treatment frequently develops post-surgical complications such as infections, fistulas and viscera-to bowel adhesions, leading to pain, recurrence and even implant failure. Among many functionalization approaches which have been studied, not absolute disappearance of adhesions occurred, that, together with insufficient porosity and fluid permeability, represent the risk for post-operative seroma formations, in some cases restricting the cells' proliferations on damaged sites, thus suppressing their viability. In the contribution, innovative strategy for the fabrication of bio-active (PP_{mesh}) – micro-structurally generated gelatin (GEL_{scaffold}) composites, containing *in-situ* integrated, antimicrobially-active ε-poly-lysine (εPL), will be presented. The anti-adhesive potential, bio-stability, antibacterial and radical-scavenging activity, as well as *in vitro* cytotoxicity of fabricated composites will be discussed in means of preparation conditions.

EXPERIMENTAL METHODS. PP_{mesh}-GEL_{scaffold} composite was fabricated by temperature-controlled cryo-process and EDC/NHS cross-linking chemistry (Fig.1). For that purpose, oxygen plasma PP_{mesh} pre-activation was performed and analysed, related to carbonyl-type functionalities (XPS; FTIR) and its integration to GEL_{scaffold} was identified (FTIR; SEM). The micro-structuring (FM), biodegradation profile (gravimetrical measurement) and rheological properties (rheometry) of composites were examined in function of preparation parameters. Moreover, the integration of εPL within GEL_{scaffolds} was identified (DSC) and its releasing profile demonstrated (HPLC/GPC). Finally, the fibrin-related anti-adhesive potential (protein adsorption), antioxidative (ABTS radical scavenging capacity) and antibacterial properties, as well as cytotoxicity (toward human ASC cells) of composites were examined.

RESULTS AND DISCUSSION. Prolonged oxygen-plasma treatment generates higher amount of oxygen-containing functionalities on PP_{mesh} surface (preferably carboxyl type) resulting in better integration with GEL molecules than shorter treatment. Moreover, the μ-porosity gradient of GEL_{scaffold} within the composite (Fig. 2) may be modulated in 50-100 μm range at top-side to a loosely-porous on the bottom side by preparation parameters variation. The long-lasting GEL coating (> 2 months under incubation in collagenase-containing physiological media), provides ~60% reduction in fibrinogen adsorption. On the other hand, the εPL-releasing profile shows prominent dependence of cross-linking extent, affecting the antimicrobial activity against G+ *S. aureus* and the G- *E. coli*, which

positively correlates with pH and εPL concentration (causing up to 100% bacteria reduction), while negative correlation with EDC concentration was measured. Non cytotoxicity to human ASC cells after one week of incubation (excluding the sample with low εPL concentration) confirms composite biocompatibility, thus suitability for biomedical applications.

Figure 1 Immobilization of GEL to PP_{mesh} using oxygen-plasma pre-activation and EDC/NHS chemistry.

Figure 2 FM images presenting the top (A) and bottom (B) side of PP_{mesh}-GEL_{scaffold} composites.

Figure 3 Photographic images of PP_{mesh} (left) and PP_{mesh}-GEL_{scaffold} composite (right).

CONCLUSION. Presented 3D and μ-structured PP_{mesh}-GEL_{scaffold} composites (Fig. 3) demonstrate high potential for active abdominal hernia repair treatments where intra-abdominal adhesions and bacterial-related infections are issues. Biomimetic nature and proved *in vitro* non-cytotoxicity is expected to provide appropriate environments for on-site cells, thus anatomically and physiologically appropriate tissue regeneration.

ACKNOWLEDGMENT. The authors acknowledge dr. Cristina Buemi (Company for production of prosthetic meshes DIPROMED, Turin, Italy) for providing the PP meshes, dr. Janez Štrancar and dr. Janez Kovač from Jožef Štefan Institute, Ljubljana Slovenia for performing the FMS and the XPS analysis, respectively.

Bioresorbable Polymer Based Novel Quick Vascular Closure Device (QVCD)

INTRODUCTION

Following arterial access procedures traditionally the hemostasis of the arteriotomy hole is achieved by manual compression. This is a labor and time consuming procedure followed by bed rest, extending the length of hospital stay. Still complications like fulminant bleeding and hematoma are common. Newer techniques try to reduce physician and nursing time by complicated, more or less automated suture devices, local application of hemostyptics or using metal clips and staples. These techniques have the disadvantage of being too time consuming, expensive or not efficient enough¹.

Our aim is to develop a self-expanding vascular closure device made from bioresorbable elastic polymer that can be applied through the placed introducer sheath. The advantages of the new VCD are cost efficient production by injection molding, quick application, easy instrumentation and early ambulation of the patients.

EXPERIMENTAL METHODS

Special bioresorbable block-co-polymers with soft-segments of glycolide, caprolacton and trimethylene carbonate have been synthesized. The chemical and mechanical degradation was determined in in vitro tests on injection molded plates in Sørensen's buffer solution.

Figure 1: First simplified molded VCD (left) and placement in the vessel wall with application system (right)

A simplified VCD was designed², a mold was build, and the molded parts were structured with CO₂-laser. The material with appropriate bending and degradation behavior was chosen for the injection molding of the first VCD specimen. A simplified application system was designed and used for first in vitro tests of the VCD (Figure 1) using porcine arterial vessels.

RESULTS AND DISCUSSION

Figure 2: VCDs placed in porcine vessel in vitro

The in vitro tests proved that the new VCD can be placed in the arteriotomy hole (Radiofocus Introducer II, Fr. 8) with minimal leakage. Degradation times could be adapted to vessel healing time of 7-14 days in in vitro test.

CONCLUSION

The in vitro testing of the new quick VCD shows the feasibility of the novel vascular closure technique. An improved design based on the in vitro results will be tested in an animal model in the next step.

INTRODUCTION

For the treatment of pulmonary air leaks and anastomotic sites between living tissues, surgical sealants have been widely used in clinical field. Fibrin sealant is a typical sealant which consists of human blood components, and its proportion is about 70 % in Japan. Fibrin sealant has excellent biocompatibility and versatile, however, it does not possess sufficient sealing effect because of its low interfacial bonding strength to tissues. Therefore, the molecular design of a tissue sealant which can adhere to a living tissue and organs under wet environment during surgery is required. In our previous study, we have shown that tissue adhesives containing hydrophobically modified porcine-derived gelatins showed excellent bonding strength onto fresh vascular media compared with non-modified gelatin^{1,2)}. However, porcine-derived gelatin solution with high concentration has low fluidity at room temperature because of its high contents of imino acids such as proline and hydroxyproline and is required to heat to use as a sealant.

In this study, we have chosen cod-derived gelatins (cGln) instead of porcine-derived gelatin as a base material for surgical sealants because it has low transition temperature due to its low contents of imino acids including proline and hydroxyproline. We synthesized various hydrophobically modified cGlns (hm-cGln) with different hydrophobic groups and introduction ratios and evaluated their sealing effects on fresh vascular tissue (blood vessel) by combining hm-cGlns with polyethylene glycol-based crosslinker (4S-PEG)³⁾.

EXPERIMENTAL METHODS

Modification of cGln with hydrophobic groups was carried out by nucleophilic substitution reaction of the amino group with fatty acid chlorides or cholesteryl chloroformate in dimethyl sulfoxide. Modification ratio of hydrophobic groups was calculated by determination of residual amino group using trinitrobenzenesulfonic acid. The measurement of burst strength for the porcine large intestine and blood vessel was performed according to the method reported as ASTM (F2392-04). As shown in Figure 1, the test sample with 15mm in diameter, 1mm in thickness was prepared. After opening pin hole with 3mm in the center of the sample, sealant composed of hm-cGlns and 4S-PEG was applied at fixed diameter and thickness. The burst strength was then measured by running a saline from the lower portion of the tissue at a flow rate of 2 ml/min at 37 °C.

RESULTS AND DISCUSSION

Hm-cGlns were successfully synthesized by the method as we reported previously^{1,2)}. By changing initial concentrations of fatty acid chlorides, each hm-cGln with three different modification ratios of hydrophobic groups was obtained. The burst strength of hexanoyl group modified cGln (Hx-cGln)-based sealants against fresh porcine blood vessel was 2-fold higher than that of original cGln (Org-cGln)-based sealant under fixed 4S-PEG concentration. Significant dependency of Hx content in cGln on burst strength was not observed. While, burst strength of cholesteryl group modified cGln (Chol-cGln)-based sealants increased up to the modification ratio of 8.3 mol%, then decreased. Highest burst strength of Chol-cGln-based sealant was 12-fold higher than that of fibrin sealant and 3-fold higher than that of Org-cGln-based sealant. Decrease in the burst strength at high Chol content of cGln is due to the increased inter/intra molecular aggregation of Chol-cGln and subsequent reduced penetration of Chol-cGln into vascular tissue. From the observation of fracture surface after burst strength measurement, the fracture area of Org-cGln-based sealant was more extensive than that of Chol-cGln-based sealant. And, Chol-cGln-based sealant still remained on the surface of vascular tissue. These results indicated that the introduction of hydrophobic groups effectively enhanced the tissue penetration of sealants and, increased the interfacial strength between tissue and sealant.

CONCLUSION

We developed surgical sealants which have high interfacial strength by combining hm-cGln with 4S-PEG. Highest burst strength against blood vessel was 3-fold higher than that of Org-cGln-based sealant by introducing hydrophobic groups. Therefore, our sealants can be applied in the field of cardiovascular surgery as well as thoracic surgery.

INTRODUCTION. Pectin is a complex natural polysaccharide present on the cell wall of higher plants. Despite the well-known use in the food industry as a gelling agent, only recently pectin started to be explored in the pharmaceutical and medical fields¹. Concerning regenerative medicine strategies, just a few studies are available²⁻⁴. The present work reports, for the first time, the ionotropic internal gelation of pectin as an *in situ* cell-delivery system using the CaCO₃/D-glucono-δ-lactone (GDL) gelation-triggering system. Since there is no medical grade or ultrapure pectin commercially available yet, pectin was purified before modification with an RGD-containing peptide to promote cell adhesion. The gelation kinetics of the hydrogels formed was evaluated by rheometry. Human mesenchymal stem cells (hMSCs) were embedded within the hydrogels and their behaviour evaluated. Finally, acellular pectin hydrogel discs were subcutaneously implanted in mice for the assessment of their *in vivo* degradation.

EXPERIMENTAL METHODS. Low-methoxyl citrus pectin (Classic CU 701) was a gift from Herbstreith & Fox (Germany) (RAWpec). RAWpec was purified (PURpec) using an adapted protocol⁵. Efficiency of purification was assessed by a Micro BCA Protein Assay (Pierce Biotechnology, USA), fluorescence spectrometry⁶, and Endosafe™-PTS system (Charles River, USA). PURpec was covalently grafted with the oligopeptidic sequence (Gly)₄-Arg-Gly-Asp-Ser-Pro (G₄RGDSP, Genscript, USA) by carbodiimide chemistry⁷ (RGDpec). Pectin was characterized by GPC/SEC and FTIR spectroscopy. Rheological properties of gel-precursor solutions and hydrogels were determined using a Kinexus Pro rheometer (Malvern, UK). hMSCs (8x10⁶ cells/mL) were mixed with the precursor solutions of RGDpec and non-modified pectin (BLKpec) at final concentrations of 1.5 and 2.5 wt% (14 days of culture). Metabolic activity was assessed by a resazurin-based assay, cell viability by a live/dead assay, and cell morphology and extracellular matrix (ECM) deposition were imaged using a confocal microscope (Leica SP2 AOBS). After implantation of acellular RGDpec hydrogel discs for 1 week in the dorsum of mice (C57BL/6), samples were harvested and stained with Safranin-O/Light-green (Sigma). Hematoxylin was used as counterstain.

RESULTS AND DISCUSSION. Purification lowered the content of protein on ca. 70%, polyphenols in 52%, and endotoxins levels in 96%. FTIR spectra indicated that the purification method did not affect pectin structure. SEC analysis showed that the M_w, the polydispersity index and intrinsic viscosity of RAWpec

and PURpec were similar. The UV spectrum of RGDpec confirmed that the RGD peptide was effectively grafted to the polymer. Rheometry studies allowed the optimization of pectin gelation towards cell embedding, with stabilization of hydrogels viscoelastic properties within 1h at 37°C (phase angle below 10°). Entrapped hMSCs were metabolically active and viable throughout the culture time within all pectin hydrogels. However, major differences were found in terms of cell morphology, as both the modifications in the pectin chemistry (RGD-grafting) and their physical properties (1.5 and 2.5 wt%) influenced hMSCs behaviour. Within RGDpec matrices hMSCs were able to spread and establish contacts with each other, leading to the establishment of an intercellular network. Cells were able to migrate outwards the matrix, populating the surface of the hydrogels and depositing endogenous ECM. The opposite could be observed for the non-functionalized matrices. After 7 days of culture, the stiffness of RGDpec was higher than BLKpec matrices. Also, the 1.5 wt% RGDpec hydrogels presented a higher stiffness than that of the 2.5 wt% ones, probably due to the softer nature of the former, offering less resistance for cells to deform the surrounding matrix, thus leading to the observed matrix contraction and establishment of a denser cellular network. The preliminary *in vivo* studies showed that a lower polymer content led to a higher degradation rate. The 1.5 wt% hydrogels presented a higher number of fragments, which were smaller and more spread throughout than the ones of the 2.5 wt% hydrogels.

CONCLUSION. Purified RGD-grafted pectin is a versatile biocompatible and biodegradable biomaterial, adequate for the preparation of *in situ* gelling cell delivery systems.

INTRODUCTION

Poly-blend (mixtures of synthetic and natural polymers) nanofibers can mimic the tissue structure by providing surface features of native tissue that promote cell survival. In the current study, blends of poly- β -caprolactone, poly-L-lactic acid and gelatin polymers used to construct 3D scaffolds in a double-layer format. With the aid of a growth factor controlled release system, scaffolds were also made biologically active.

EXPERIMENTAL METHODS

Nanofibrous double-layer matrices were prepared by electrospinning technique with the bottom layer formed from PCL (poly- ϵ -caprolactone)/PLLA (poly-L-lactic acid) blend nanofibers and the upper layer from PCL/Gelatin blend nanofibers. Bottom layer was designed to give mechanical strength to the system, whereas upper layer, containing the natural polymer gelatin, was optimized to improve the cell adhesion. Gelatin microspheres were incorporated physically in the middle of these two layers for controlled growth factor delivery. This sandwich system prevented microsphere leakage from the scaffold. Whole procedure was described elsewhere¹.

Cell differentiation on the designed scaffold system was studied using adipose tissue derived stem cells (ADMSCs) and microspheres within the scaffolds were loaded with bone morphogenic protein-2 (BMP-2) which is a well established pro-osteogenic morphogen. Differentiation of ADMSCs towards osteogenic lineage was evaluated by alkaline phosphatase (ALP) assay and von Kossa staining for the detection of mineralization. Collagen type-I immunostaining was carried out to examine ECM formation by ADMSCs on electrospun fibrous mats.

RESULTS AND DISCUSSION

Experimental samples used were: (S1) PCL/PLLA – PCL/Gelatin double layer matrices with BMP-2 loaded microspheres, (S2) PCL/PLLA – PCL/Gelatin double layer matrices with unloaded microspheres and (S3) PCL/PLLA one layer matrices.

ALP activity assays showed that ADMSCs on the scaffolds undergoing osteogenic differentiation demonstrated higher ALP activity in the first week, as an early marker of osteogenesis, after which ALP activity decreases while mineralization increases.

Visualization of calcium deposits was done by von Kossa staining and results showed that ADMSCs cultured both on the scaffolds and TCPs produced a mineralized matrix. Mineral nodules (represented by the

brown/black deposits) were scattered in the samples (Figure 1). Since mineralization is a late osteogenic marker and the final phase of bone formation, staining of calcium deposits increased at the later periods of incubation (14 days vs 24 days). It was noticed that stained scaffolds containing BMP-2 (S1) showed darker staining indicating accelerated biomineralization after 14 and 24 days of incubation compared to the samples that do not contain BMP-2 (S2) and both exhibited higher mineralization when compared with S1.

Figure 1 : von Kossa staining: Stereomicroscopy images of experimental groups (left column) with their blank samples (right column) on day 24

CONCLUSION

All samples supported the proliferation of ADMSCs. Both the sandwich-like architecture of the constructed scaffolds and presence of hydrophilic gelatin on the upper layer promoted improved migration and differentiation of ADMSCs.

INTRODUCTION

The design of bone tissue engineered constructs for future clinical application demands patient customizable 3D structures. These need to be able to sustain the mechanical solicitations, to support cellular functions and to induce bone formation. Our methodology is based on a combination of multiple techniques. This permits us to optimize and customize the final 3D structure at a multi-level scale by using human and marine-origin materials for the production of the primary nano/sub-micro environment that will dictate cell fate. 3D prototyped macro-porous scaffolds where subjected to layer-by-layer assembling and freeze-drying for hierarchical (hier) structuring with nanocoatings and micro-fibrillar structures. Those structures, rich in autologous growth factors (GFs) from human platelet's lysate (hPL), are stabilized throughout marine-origin polysaccharides functional groups and physical crosslinking. The potential of these nano/microenvironments for the conduction and induction of osteogenic differentiation of human adipose derived stem cells (hASCs) was assessed.

EXPERIMENTAL METHODS

Poly(ϵ -caprolactone)-PCL, ι -carrageenan and chitosan where obtained from Sigma-Aldrich. Human platelet's lysate was obtained as explained elsewhere.¹ The assembling of the polyelectrolytes (PEs) with hPL was studied by QCM-D. PCL scaffolds were prepared using a BioplotterTM rapid prototyping machine and modified by dipping LbL and freeze-drying.² hASCs were cultured in osteogenic (+dexamethasone, +Dex) and osteoconductive media (-Dex). After 28 days in culture, samples were harvested and characterized by several techniques for calcium by Alizarin Red S staining and SEM-EDS; for immuno-detection of osteocalcin (OC); for fat deposition by oil red O staining; and osteogenic-related gene expression by qPCR.

RESULTS AND DISCUSSION

Different types of microenvironments were assembled inside of the PCL scaffold pores: fibrilles and coatings obtained from 15 (PCL Hier hPL) and 30 (PCL Hier hPLx2) LbL dipping cycles, with and without hPL – see Fig.1.

Fig. 1. PCL scaffold before and after the modification (PCL Hier) with the fibrillar structures hydrated and contrasted in black.

The new structures supported hASCs osteogenesis both in the presence and absence of hPL in medium containing Dex –Fig.2. These structures conduced the deposition of CaP not only onto the surfaces (as in the case of PCL) but also in the void spaces of the pores. With the presence of these fibrillar structures the biomineralization occurs starting from the fibrilles in direction to the pores wall.

In the absence of Dex, the presence of hPL and the hierarchical structures synergistically induced the deposition of mineralized matrix and osteocalcin (Fig. 3).

Fig. 2. Alizarin Red S staining on several conditions after 28 days in culture.

PCL Hier hPL (15 cycles) was able to induce the hASCs deposition of OC and CaP in the absence of Dex – Fig.2, 3. Therefore, the environment created in PCL Hier hPL samples has triggered the differentiation of hASCs into the osteogenic lineage.

Fig. 3. Immuno-detection of osteocalcin (green) and nucleus (blue); Alizarin Red S staining (red).

PCL Hier hPLx2 has not shown mineralized matrix, nor has OC when cultured without Dex. This result reveals that contrarily to PCL Hier hPL, the nano and microenvironment of PCL Hier hPLx2 was not adequate for bone formation induction.

CONCLUSION

The developed methodology allows the preparation of 3D scaffolds with multi-level tunable nano- and micro-environments that highly affect cell fate. The structuring method has shown to be effective for the introduction and stabilization of osteoinductive factors derived from hPL. By playing with the structuring parameters, the density of the hPL presented to cells, the profile and even the spatial-temporal release, highly bioactive 3D tissue engineered bone constructs can be created.

Effect of Cyclic Compression on Osteogenesis of Self-Assembled Collagen-Cell Seeded Microspheres

Maryam Shariatzadeh, Cécile M. Perrault, Damien Lacroix

INSIGNEO Institute for in silico medicine, Department of Mechanical Engineering, University of Sheffield, UK
m.shariatzadeh@sheffield.ac.uk

INTRODUCTION

Mechanical forces such as shear stress, compression and 3D environment, can be used to control differentiation of Mesenchymal Stem Cells (MSCs)^{1, 2}. In this study, a novel microfluidic chamber is designed to apply mechanical stimulation on soft cellular microspheres. It is hypothesised that cell morphology and expression of osteogenic cell marker is different when cells are subjected to dynamic compressive strains.

EXPERIMENTAL METHODS

A microfluidic chamber was made of polydimethylsiloxane (PDMS) with a main channel of 1 mm width and constrictions of 0.5 mm (Fig. 1). Bovine collagen type I (Life Technologies) with concentrations of 2 mg/ml and 2450 heMSC/MG63 cells per 5 µl droplet was produced through gelation. The microspheres were passed through the constriction at a flow rate of 320 µl/min for 3 cycles/day for 3 days starting at day 3 post-encapsulation. Cell viability, proliferation and bone markers alteration were monitored and compared before and after compression with the same dynamic compression regime applied by a Bose biodynamic bioreactor.

RESULTS AND DISCUSSION

Cell viability and proliferation reduced after compression cycles compared to controls. Cell proliferation dropped gradually by 14% on day 7 post encapsulation and cells presented more rounded morphology immediately after and up to day 3 post compression compared to the initial cell seeding. (Fig. 2, & 3). Bovine Collagen demonstrated an efficient micro environment for cellular growth which supported cell proliferation and viability up to 35 days post encapsulation. Fluid flow rate above 320 µl/min caused damage to collagen microspheres and released the cells, while flow rate below 100 µl/min caused microspheres attachment to PDMS. Cell viability and proliferation of compressed cells increased steadily by 23% there compared to 30% growth in controls (Fig. 3).

Fig. 1: Microfluidic chamber with constricted channel shown in the right.

Fig. 2 : Collagen-MG63s microspheres day 7 post-encapsulation control (left), sample (right).

Fig. 3 : MG63 cell proliferation before and after compression. Error bars are standard deviation of four samples.

CONCLUSION

The microfluidic chamber enables chemical and mechanical stimulation of cells in a controlled environment, while reducing the overall volume of the systems. Such a system provides both reduction in cost and possibility of high throughput testing. The application of a compressive force on the cell-seeded microspheres supported cell viability and enhanced cell proliferation 24 h after ending the compressive cycles. However, extended period of cell monitoring is required to investigate the long term effects of compression. Application of compression cycles on MG63/heMSC cells could be used as a model to study the effect of mechanostimulation on osteogenesis.

Ultra-thin Bioglass Fibres with Controlled Structures for Biomedical Applications

Yangyang Li¹, Ding Zhao^{1,2}, Binbin Li¹, Qihong Zhang¹, Yike Fu¹, Mingwei Chang², Xiang Li^{1*}

^{1*} Department of Materials Science and Engineering, Zhejiang University, P.R.China. xiang.li@zju.edu.cn

INTRODUCTION

Sol-gel bioactive glass (SBG) has become one of the most important biomaterial groups since its discovery by Larry Hench in 90s due to its various advantages, such as strong bioactivity, microstructure control feasibility and large surface area [1]. Recently, ultra-thin SBG fibres with manipulated microstructures have been widely considered as a promising candidate for bone scaffold. The protein absorption and releasing behavior of a scaffold material plays a key role in tissue repairing progress [2]. Finding an efficient approach to manipulating the protein release kinetics can be rather important to improve the performance of SBG bone scaffold in clinic, but yet remains a challenge. In this study, a range of ultra-thin SBG fibres with well-controlled bovine serum albumin (BSA) releasing behaviors were synthesized using electrospinning. A feasible and effective protein absorption/release control method by only varying the sol-gel reaction condition was therefore established for SBG scaffold materials.

EXPERIMENTAL METHODS

TEOS, triethylphosphate (TEP) and calcium nitrate ($\text{Ca}(\text{NO}_3)_2$) were mixed in ethanol with a certain ratio. Water was added in the solution with four different ratios (Water/TEOS (X) = 2, 4, 6, 8 mol%) to control the hydrolysis process of SBG precursor. After stirring for 2h, PVP solution was added as electrospinning carrier. Four precursors prepared were transferred into a single nozzle electrospinning setup. The distance and voltage applied between the needle tips and the collector were set at 15 cm and 6–8kV, respectively. The as-spun BG fibres were then heat treated in air at 600°C to eliminate organic additives. The SBG fibres were characterized using SEM, TEM and FTIR. Subsequently, BSA protein was loaded on SBG fibres by immersing in two different solutions, BSA solution and BSA/SBF mixture, for 30 hours. The protein loaded fibres were then immersed in PBS solution, and the BSA release phenomena were studied using UV.

RESULTS AND DISCUSSION

In the bioglass sol-gel reaction, the hydrolysis process is important for its microstructural characteristics. In general, higher hydrolysis degree may induce more integrated Si-O-Si network. In our study, it was found that, under the same electrospinning condition, all four SBG fibres present uniform morphology. With the X ratio increased from 2 to 8, the fibre dimension increases from ~200nm to ~500nm, as shown in Fig 1a. This is due to the higher precursor viscosity induced by the enhanced hydrolysis degree. The FTIR study shows that the Si-O-Si asymmetric, stretching and symmetric bending modes, corresponding to the peaks at 1070 cm^{-1} , 800 cm^{-1} and 478 cm^{-1} , are remarkably enhanced with the increased X ratio. The increased water content induces the higher hydrolysis degree and the subsequent polycondensation reaction of silica network former. In

consequence, the Si-O-Si network integrity of the SBG fibre can be enhanced with higher X value.

Fig.1. (a) SEM and (b) FTIR of SBG fibers with different X ratio.

When four types of SBG fibres were directly immersed in BSA solution. The releasing kinetics of all fibres presented similar characteristics. ~60% of BSA released within the initial ~5h. In contrast, when immersed in SBF/BSA mixed solution, only ~30% of BSA was released within initial ~5h for all fibres (Fig 2). This is due to the ‘anchoring’ effect of the porous apatite layer formed which prohibits the releasing of BSA molecules. More importantly, when X ratio decreased from 8 to 2, more sustained BSA releasing behaviour was observed. Higher X ratio induces more integrated Si-O-Si network, and thus weakens the bioactivity of SBG fibres. Consequently, less apatite contents with higher porosity is formed on the fibre surface when protein loading, which weakens its ‘anchoring’ effect to BSA molecules.

Fig.2. The protein release behavior of four SBG fibers loaded BSA in (a) BSA solution and (b) BSA/SBF solution.

CONCLUSION

A range of SBG fibres, ranging from ~200nm to ~500nm in thickness, with different Si-O-Si network structures were successfully synthesized using electrospinning. By loading BSA protein in SBF/BSA mixed solution, SBG fibres showed sustained and well-controlled BSA releasing kinetics, due to its controlled BG network integrity and bioactivity induced by the manipulated sol-gel hydrolysis degree. This study has therefore paved the way to the research of future functionalized SBG fibrous scaffold materials.

Serious adverse event of woven fabrics made of bioactive glass fibres of the Na₂O-K₂O-MgO-CaO-B₂O₃-P₂O₅-SiO₂ system in the rabbit spinal fusion model

Jane P. Frantzen,^{1,2} Jessica J. Alm,¹ Petteri Lankinen,¹ Niko Moritz,¹ Matias R  ytt  ,³ Hannu T. Aro^{1*}

INTRODUCTION

Bioactive glasses (BGs) of the system Na₂O-K₂O-MgO-CaO-B₂O₃-P₂O₅-SiO₂ were developed to provide BGs with larger working range¹. Of this system, BG 13-93, BG 1-98 and BG 3-98 have been found suitable for processing into fibres, microspheres and woven fabrics. We previously evaluated a woven fabric made of BG 1-98 and PLGA 80/20 (PLGA₈₀) fibres in a rabbit femur model, without any adverse effects². The current study aimed at evaluating the same fabric and a corresponding load-sharing 3D composite plate in a rabbit model of spinal fusion. Due to unexpected occurrence of serious adverse events the study had to be terminated before completion.

EXPERIMENTAL METHODS

Woven fabrics (25x45 mm) of plain weave canvas-type were made of BG 1-98 (SiO₂ 53%, Na₂O 6 %, CaO 22%, K₂O 11%, MgO 5%, P₂O₅ 2 %, B₂O₃ 1% by weight) fibers (20-30 µm) and PLGA₈₀ fibres (200 µm), or PLGA₈₀ fibres alone (control). BG fibres were multiplied to 70-140 filament threads for weaving. PLGA₈₀ monofilaments were used as warp threads². A load-sharing 3D composite plate (3x15x45mm) was made from hybrid knitwear of BG 1-98 fibres, PLA₉₆ and PLA₇₀ fibres.

The implants were tested in an established spinal fusion model of the rabbit. The animals were divided into four groups according to the used implants (Table 1). The implants served as the surgical beds for autogenous bone grafting. The control group (Group 1) had autogenous bone grating alone. Spinal fusions were evaluated at 6 weeks by X-ray, CT, biomechanical testing and histology. The original study plan contained 8 animals per group operated in a randomized order.

In vitro experiments using human bone marrow derived mesenchymal stromal cells (hMSCs) and methods previously established in our lab³ were conducted in an attempt to explore cellular responses to the implants. The analyses included pH monitoring, cell viability and osteogenic differentiation assays.

RESULTS AND DISCUSSION

Of the 28 operated animals, 21 completed the follow-up. After 7 animals out of 14 in the BG groups (Group 3 and 4) were lost due to unexpected postoperative death (n=4), or had to be euthanized, the experiment was terminated (Table 1). In the BG/PLGA₈₀ group, 2 animals were euthanized due to intractable pain and paraparesis. One animal in the 3D composite group was euthanized due to intractable pain and autophagia.

Infectious causes were ruled out by microbiological and histological samples of autopsies.

In the BG/PLGA₈₀ group, none of the completed animals had histological fusion. Tissue samples revealed severe local inflammation and necrosis. In the neuropathological examination, muscle samples showed necrosis, multinuclear macrophages, increased fibrosis capsule, increased endomysial fibrosis with accumulations of inflammatory cells. The sensory ganglia at level of fusion showed signs of edema. Neither necrotic muscle fibers nor inflammatory changes were observed above the fusion area.

Table 1. Summary of study outcome

Group #	Implants used with autogenous bone grafting	# Animals	Detected fusion at 6 weeks	Serious adverse events #
1	Control (autograft)	n = 8	81%	0
2	PLGA ₈₀	n = 6	25%	0
3	BG 1-98 /PLGA ₈₀	n = 11	0%	n = 6 (55%)
4	3D composite (BG 1-98/ PLA ₉₆ / PLA ₇₀)	n = 3	0%	n = 1

In vitro experiments with hMSCs showed growth inhibition next to BG fibers and radical pH changes, compromising cell survival and differentiation.

The current adverse events were unexpected. The underlying mechanisms remain unclear. It is possible that the high surface area of fibers with too high dissolution rate caused rapid increase of pH and toxic concentrations of ions.

CONCLUSION

The woven fabric made of BG 1-98 and polymer fibers resulted in serious adverse reactions, necessitating early termination of the study. *In vitro* testing of the fibres and fabrics with human MSCs supported the *in vivo* findings. We recommend a systematic safety evaluation of novel BG formulations before clinical use.

INTRODUCTION

Glass ionomer cements (GICs) are used extensively as restorative materials, due to their ability to release and uptake fluoride, to form strong chemical bonding to the tooth surfaces, as well as have good handling properties, no shrinkage on polymerization and minimal toxicity compared to other restorative materials¹. On the other hand, GICs are considered as a vital source of calcium, phosphorous and fluoride ions. These ions have an ability to form apatite similar to the tooth minerals (hydroxyapatite, HA) at favourable conditions. Furthermore, it is believed that GICs have a beneficial ability to form apatite with time at the interface between the filling and the oral environment. Therefore, GICs are at the essence of the atraumatic restorative treatment (ART), which is an alternative technique for dental caries management.

The remineralising ability of GICs has not been studied extensively and factors affecting this process are poorly understood. Consequently, this study was aimed to investigate the remineralisation of GICs and to establish how it could be promoted via incorporation of remineralising agents.

EXPERIMENTAL METHODS

Fluorine-free and fluorine containing ionomer glasses based on $4.5\text{SiO}_2\text{-}3\text{Al}_2\text{O}_3\text{-}1.5\text{P}_2\text{O}_5\text{-(}5\text{-x)CaO-xCaF}_2$, where $x=0,1,2,3,3.5,4$, were synthesised with varying calcium oxide (CaO) and calcium fluoride (CaF₂) proportions. The Ca:P ratio is 1.67 for all the glasses which is kept equal to Ca:P ratio of HA. The fine glass powders were mixed with the poly(acrylic acid) in powder form and then with water at a specific ratio P:L=5:1. Different percentages 0, 5, 10, 15% of HA and FA was substituted for the original ionomer powder in order to accelerate the remineralisation of GICs. Immediately, the cement discs were placed in artificial saliva (AS) at pH=6.5, and kept at 37°C for different time points for 7-180 days. After a certain time, the samples were collected via filtration, dried, ground into a powder and further characterised. The formation of apatite in GICs has been evaluated using Fourier Transform Infra-Red (FTIR) and Solid-State Nuclear Magnetic Resonance (NMR) Spectroscopies. Wilson's oscillating rheometer was used to measure the handling characteristic of GICs with and without addition of remineralising agents. The concentration of the ions, released from GICs after immersion in AS were measured by Inductively Coupled Plasma-Optical Emission (ICP-OES) Spectroscopy.

RESULTS AND DISCUSSION

The working and the setting times of GICs were decreased with increasing CaF₂ content while increased when increasing the substituted amount of HA. The ²⁷Al NMR spectra cement showed the conversion of Al(IV) to Al(VI) as the setting proceeds. The peaks around 50-53ppm and -4ppm are attributed to the presence of Al(IV) and Al(VI) respectively. This is in a good agreement with the previous study². Additionally, the ²⁷Al NMR showed that increase in fluoride amount in the base glass indirectly affects change of the coordination number of Al from four to six during the setting reaction. The formation of apatite in GICs on immersion in AS was probed with ³¹P NMR spectroscopy. The ability and the rate of apatite formation from GICs were highly depended on the composition of the ionomer glasses. Furthermore, the P:L ratio has found to have an important role in apatite formation. The apatite was partially consumed during the setting reaction. The deconvolution was done to quantify the amount of apatite consumption during the reaction. The phosphorous environment in the GICs before and after the immersion in AS compared to the original glasses will be discussed. A negligible quantity of Al was released from all GICs compositions. This confirms that Al was consumed during the setting reaction to form Al polysalts.

CONCLUSION

The potential ability of GICs to remineralise is a significant advantageous feature distinguishing the GICs from the other restorative filling materials. The concentration of calcium and phosphate ions is not the only factor promoting the remineralisation process; also it depends upon the composition of ionomer glasses as well as powder to liquid ratios.

The Retarding Effect of Zinc Oxide on Dissolution and Apatite Formation of a Fluoride Containing Bioactive Glass

Xiaohui Chen¹, Priyen Shah², Mohammed Mneimne², Robert G. Hill², and Natalia Karpukhina^{2*}

¹School of Dentistry, The University of Manchester, UK

^{2*}Barts and The London School of Medicine and Dentistry, Queen Mary University of London, UK,
n.karpukhina@qmul.ac.uk

INTRODUCTION

Fluoride containing bioactive glasses are attractive for incorporation into remineralising toothpastes for three reasons: (i) they form fluorapatite which is much more acid durable than hydroxycarbonated apatite; (ii) they release fluoride that is known to inhibit apatite dissolution and caries formation; and (iii) they have a more disrupted glass network with lower glass transition temperatures and should be softer and are therefore less abrasive towards enamel.

Fluoride containing bioactive glasses were originally studied by Spilman and Hench¹ in the 1970s but there has been increased interest in fluoride containing glasses in recent years including glasses with high phosphate².

Zinc Oxide has been incorporated into bioactive glasses³ and it is potentially attractive for use in toothpastes, since zinc salts are added to existing toothpastes where the zinc has a bacteriocidal action, an anti-caries action and an anti-gingivitis action.

This study examines the influence of ZnO incorporation on the dissolution and apatite forming ability of a high phosphate fluoride containing bioactive glass. Since ZnO is thought to act as an intermediate oxide it has been substituted for SiO₂ with additional CaO and Na₂O to charge balance the ZnO₄ tetrahedra and maintain a fixed network connectivity.

EXPERIMENTAL METHODS

Bioactive glasses with and without 2 mol% of ZnO were synthesised and studied. Glass degradation and apatite formation was followed by X-ray diffraction (XRD), Fourier transform infrared (FTIR) spectroscopy and magic angle spinning nuclear magnetic resonance (MAS-NMR). The ions in solution following immersion in Tris buffer were determined by inductively coupled plasma – optical emission spectroscopy (ICP-OES) and by a fluoride-ion selective electrode.

RESULTS AND DISCUSSION

The zinc free glass formed a fluorapatite (FAP) like phase in under two hours that was evident in the XRD patterns and FTIR spectra. The zinc containing glass did not show sharp XRD peaks of the apatite phase until 24 hours immersion and did not show the characteristic $\nu(\text{PO}_4)$ peaks of a crystalline orthophosphate in the FTIR spectra. The ³¹P and ¹⁹F MAS-NMR spectra showed that the zinc free glass formed FAP in under two hours and the dissolution of the glass was complete in less than 6 hours. The zinc containing glass also formed a FAP, but the apatite formed was in smaller amounts and the broader peaks indicate a more disordered apatite. The dissolution of the glass in terms of its fluoride and phosphate content was not complete in 24 hours.

CONCLUSION

Zinc oxide substitution in bioactive glass slows down rapid degradation of the bioactive glass and formation of the apatite phase. Thus, the studied composition of the zinc containing bioactive glass can be incorporated as a desensitiser into remineralising toothpaste. Sustained release of both fluoride and zinc ions from the bioactive glass can deliver therapeutic effect via toothpaste.

Hypoxia Mimicking Glasses For Use As Chronic Wound Dressings

AK Solanki¹, H Autefage¹, J Penide², F Quintero², J Pou², JR Jones¹, MM Stevens^{1,3}

¹Department of Materials, Imperial College London, United Kingdom, ²Applied Physics Department, University of Vigo, Spain, ³Department of Bioengineering, Imperial College London, United Kingdom, a.solanki@imperial.ac.uk

INTRODUCTION

Chronic wounds fail to heal within 6 weeks or reoccur frequently, and usually occur in patients already suffering from an underlying pathological condition. Patients with chronic wounds have a reduced quality of life, and treating chronic wounds has a significant economic burden to the healthcare system¹. Hypoxia can regulate many processes essential for tissue repair², such as angiogenesis and is therefore expected to promote chronic wound healing. Cobalt has been shown to mimic hypoxia and promote angiogenesis through the Hypoxia Inducible Factor-1 pathway³. Bioactive glasses have also been shown to promote angiogenesis in specific concentrations. This project aims to develop a dressing suitable for chronic wounds that promotes angiogenesis through incorporation of a cobalt containing glass. A glass composition has been developed that releases cobalt ions in a therapeutic range for at least 1 week. In parallel, formats suitable for clinical presentation have also been identified.

EXPERIMENTAL METHODS

Preparation of electrospun composite: A composite of glass particles and poly-ε-caprolactone (PCL) was produced by electrospinning. Glass particles were mixed with a solution of PCL in chloroform, and this was electrospun at a voltage of 16kV.

Preparation of glass fibres: Glass plates were produced by melting glass frit, and pouring into preheated graphite moulds. Glass fibres were then formed by laser spinning⁴.

Preparation and characterisation of glass particles: To form glass frit, carbonate precursors were melted at 1400°C and quenched into deionised water. The ion release from glass particles into TRIS buffer was measured over 1 week by Inductively Coupled Plasma – Optical Emission Spectroscopy (ICP-OES). The ability to form a hydroxy carbonate apatite layer on the glass surface was also investigated by incubating the glass in Simulated Body Fluid (SBF) for 28 days. Changes in glass structure were determined by Fourier Transform Infrared Spectroscopy (FTIR), X-Ray Diffraction (XRD) and Scanning Electron Microscopy (SEM).

RESULTS AND DISCUSSION

Glasses doped with 2 mol% cobalt oxide were produced⁵ and the dissolution behaviour of the particles in TRIS and SBF buffer was characterised. Over the period of 1 week, cobalt ions were released in a range that is expected to be therapeutic.

A composite mesh was successfully produced by electrospinning. Glass loadings up to 50 wt% have been achieved, with the particles appearing to be homogeneously distributed throughout the mesh and completely coated by PCL (Fig 1). At short timepoints,

the composite showed controlled release of all ions from the glass when compared to the glass particles alone (Fig 2). By the one week timepoint, there were minimal differences between the ion release from the powder and the electrospun composite.

Fig 1: SEM image of the PCL-glass composite containing 50 wt% glass particles.

Fig 2: Cobalt ion release in TRIS buffer comparing glass particles and the PCL-glass composite.

Glass fibres produced by laser spinning had a wide range of fibre diameters, were interconnected and show favourable handling properties (Fig 3). During the laser spinning process, the glass fibres were rapidly cooled, which allowed the amorphous structure to be retained, and no crystal phases were observed in the glass fibres.

Fig 3: SEM image of the glass fibres.

CONCLUSION

PCL-glass composites and glass fibres were produced from glasses containing 2 mol% cobalt oxide, and characterised. The glass particles allowed release of ions in a range that is expected to upregulate the HIF-1 pathway. The PCL-glass composite and glass fibres both demonstrated controlled ion release at short timepoints, which is beneficial because by preventing a burst ion release, cell toxicity is expected to be reduced. They both have excellent handling properties, and are expected to be suitable for dressing different wound types. In vitro cell studies on a fibroblast cell line are ongoing, and the results obtained from this are expected to provide further insight on the therapeutic effects of the cobalt glass, and will indicate potential cytotoxicity.

INTRODUCTION

Instructive biomaterials play a key role promoting successful tissue repair by means of regenerative medicine approaches, and are expected to contain chemical, as well as mechanical cues that will guide the regenerative process. The use of these biomaterials are optimal for **in situ tissue regeneration**, that uses the body's own regenerating capacity by mobilizing host endogenous stem cells or tissue-specific progenitor cells to the site of the injury.

This approach relies on development of **target-specific biomaterial scaffolding system** that can effectively control the host microenvironment and mobilize host stem/progenitor cells to target tissues. Herein we report the biological properties of a bioactive, biodegradable calcium phosphate glass that can control degradation process and the release of the ions (which are becoming highly relevant enhancing several regenerative responses¹). The appropriate microenvironment provided by implanted scaffolds facilitates recruitment of host cells that can be guided to regenerate structural and functional tissues².

EXPERIMENTAL METHODS

Two types of composites were developed.

1) Scaffolds of Polylactic Acid and micro particles of Calcium phosphate glasses based on TiO_2 -CaO- P_2O_5 - Na_2O system, fabricated by means of solvent casting.

2) Hybrids ormoglasses. Based on the sol-gel method, calcium phosphate glass nanoparticles and/or silicon-based ormoglass polymers were blended with, polylactic acid electrospun nanofibers.

Characterization of the scaffolds in terms of degradation, ion release, surface wettability and topography, mechanical properties and biological performance in vitro and in vivo were conducted.

RESULTS AND DISCUSSION

The solvent casting scaffolds provided excellent mechanical properties to sustain endothelial progenitor cells proliferation and differentiation, as well as vessels formation. Mechanical properties and calcium release together promoted the expression of vascular endothelial growth factor (VEGF) as well as its receptor (VEGF-R).

The nanofibrous scaffold made of PLA afforded the flexible structural support while a sol-gel processed organic-inorganic bioactive glass supplies the chemical bioactive cues.

This method allows the fabrication of scaffolds with excellent hydrophilic properties, enhanced mechanical features, great cellular adhesion and tailored nanostructured topographies and stiffness by changing glass composition. Ca^{2+} release assay showed that nanofibers released more calcium than solvent casting scaffolds and this release was sustained a long time. In

Ex vivo test for vascularization potential of both scaffolds. Nanofibers of PLA and PLA/Glass (left up and down) and scaffolds of PLA and PLA/Glass (right up and down)

vivo, both scaffolds showed the capability to induce bone and vascular formation. Vascularization tests showed that nanofibers with glass exerted a higher potential for vascular growth and penetration.

These instructive biomaterials effectively combine two features that in our experience actively participate in the activation of the progenitor cells that respond and react to stimuli from its environment: bioactivity by means of the release of calcium, that acts as a cell homing and maturation of EPCs and MSCs; and mechanical properties that act synergistically with bioactivity.

CONCLUSION

In this decade, that a new generation of biomaterials have been postulated, the need of a versatile system that can be tuned to promote cell homing and differentiation is relevant for in situ regeneration processes. The fine control of surface properties leads to mobilize cells and support adhesion as well as differentiation. Calcium phosphate glasses display these properties and this study demonstrates the capability to regenerate bone tissue as well as vascularization.

INTRODUCTION

Due to their excellent adhesion and anticariogenicity, glass ionomer cements (GICs) have been widely in dentistry. Poor mechanical properties, long setting and high solubility, however, could limit their applications^(1,2). Addition of silver amalgam has been attempted to overcome these limitations. Regardless of the improvement achieved, the fluoride release was compromised. The use of natural fibres as reinforcing agents has been recently increased. The aim of this study was therefore to use flax fibres for reinforcement of GICs. The effect of flax fibres incorporation on the setting kinetics, surface topography and micro-scale mechanical properties of GICs were investigated.

EXPERIMENTAL METHODS

Sample preparation: Short flax fibres (~2 mm length) were included at 0, 1, 2.5, 5 and 25 wt% into GICs filling materials (KetacTM Fill Plus, 3M). The samples were coded: GIC, 1FFRGIC, 2.5FFRGIC, 5FFRGIC, 25FFRGIC respectively. The powder: liquid ratio was 3:1; the mixed paste was used for the reaction kinetic study. Discs of 5 mm diameter and 2 mm thickness were used for topography and mechanical characterisation.

Setting reaction kinetics: The setting reaction kinetics of each mixed cement has been studied using ART-FTIR spectrometer (Nicollet iS10). Spectra were obtained every 2 minutes during the first 60 minutes after mixing using OMNIC software. The spectra were obtained between 400 and 4000 cm⁻¹. To compare between different compositions, the relative reaction rate and reaction extent were used.

Surface topography and mechanical properties: Samples were scanned using atomic force microscope operating in amplitude modulated force microscopy mode (AMFM, MFP-3D-Bio, AsylumResearch) at frequency of 0.5 Hz and scan size was 20x20, 10x10 and 1x1 μm. Silicon tip with nominal spring constant 40 N/m was used. Topographical images, distribution of different phases in the material and maps of stiffness and energy dissipation which corresponded with phase separation and uniformity of the material were obtained from the collected data.

RESULTS AND DISCUSSION

The setting reaction of GIC followed three stages. Initially, no absorbance changes were observed; then polyacid neutralization was characteristic to intermediate changes-Fig.1a. Further loss of polyacid and concomitant formation of polyacrylate complexes were then seen. With incorporation of flax fibres, the setting reaction followed the same stages but with slightly slower initial rates while increasing the fibres weight%-Fig.1b.

Fig.1: FTIR showing the reduction in 1707 cm⁻¹ peak indicating the progression of reaction (a) and the resultant reaction extent (b).

Qualitative imaging using AMFM showed the presence of a single phase in GIC, while biphasic structure was observed for FFRGIC-Fig. 2a&c. Both groups of material showed differences in topography (roughness); mean roughness for GIC samples was lower than for the samples with filler. Importantly, the incorporation of flax fibres was shown to increase Young's modulus with increasing about of filler content-Fig. 2b&d. The flax fibres were uniformly distributed for all tested samples and well integrated within the substrate, without visible interfacial separation.

Fig. 2: Topography and stiffness map of GIC (a, b) and 1FFRGIC (c, d).

CONCLUSION

- Flax fibres slightly reduced the initial but not the final setting reaction rate.
- A slight increase in the mean roughness was observed with incorporation of flax fibres.
- Regardless of their physical incorporation, flax fibres were uniformly distributed and well integrated within GIC matrix.
- Flax fibres produced a significant improvement in Young's modulus of GIC.

Hypoxia Mimicking Bioactive Glasses for Chronic Wound Healing

Maria Azevedo, Siwei Li, Wai Ho, Alex Burns, Luara Schoenewolf, Chris Nayar and **Gavin Jell**

Division of Surgery & Interventional Science, UCL, Royal Free Campus, London, UK, g.jell@ucl.ac.uk

INTRODUCTION

Novel methods to improve chronic wound regeneration are urgently needed. Hypoxia (low O_2 pressure) is the principle environmental cue that stimulates wound healing. The damaged vasculature of the wound causes a local drop in O_2 pressure which cells respond to via the HIF (hypoxia inducing factor) pathway. Stabilisation of HIF, following hypoxia, initiates a number of pathways important for wound healing including; α -microbial cell recruitment/activity, cell differentiation, ECM production, cell survival and the restoration of O_2 pressure through angiogenesis (Fig. 1). Furthermore in patients with chronic wounds (elderly patients and those with diabetes mellitus) there appears to be a diminished cellular ability to respond to hypoxia via HIF¹. Materials that regulate the HIF pathway could, therefore, be an attractive target in chronic wound management. Hypoxia Bioactive Glasses (HBG) containing the known hypoxia mimetic cobalt were developed to stabilise HIF-1 α and activate this wound regeneration pathway (Fig. 1).

a. Hypoxia Bioactive Glass b. Co^{2+} Stabilizing HIF-1 α c. Wound healing responses

Figure 1. (a) Resorbable HBGs release physiologically active concentrations of Co^{2+} , (b) Co^{2+} inhibits the activity of the O_2 sensitive enzyme Phd thereby enabling the nuclear translocation of HIF-1 α and (c) causing the cell-type specific activation of hypoxia responsive elements associated with wound repair.

EXPERIMENTAL METHODS

Melt-derived HBGs (SiO_2 49.5%; P_2O_5 1%; CaO 19-23%; Na_2O 26.5%; CoO 0-4%) were manufactured and characterised as previously described². Endothelial cells (ECs), macrophages (M ϕ) and fibroblasts (FBs) were cultured in appropriate media which had been pre-incubated with HBGs (0%, 1%, 2% or 4 Mol % Co^{2+}). The ability of HBGs to stabilize HIF-1 α , promote pro-angiogenic factor production (FGF, VEGF) and promote cell migration was determined by immunofluorescence and the TransAMTM HIF-1 assay kit (Active Motif[®]), ELISA (R&D systems) and the Transwell[®] migration assay respectively. Anti-microbial activity was assessed by monocyte differentiation into M ϕ and phagocytic activity determined by pHrodoTM Bioparticles[®] uptake (Molecular Probes[®]). To mimic a

diabetic chronic wound these studies were also completed in high glucose (25mM) media with D-Mannitol (to balance osmolarity).

RESULTS AND DISCUSSION

Media conditioned with HBGs increased nuclear HIF-1 α expression ($P < 0.05$ as determined by the TransAMTM assay) and by immunofluorescence (Fig. 2), suggesting that HBG stabilise HIF1 α in normoxia.

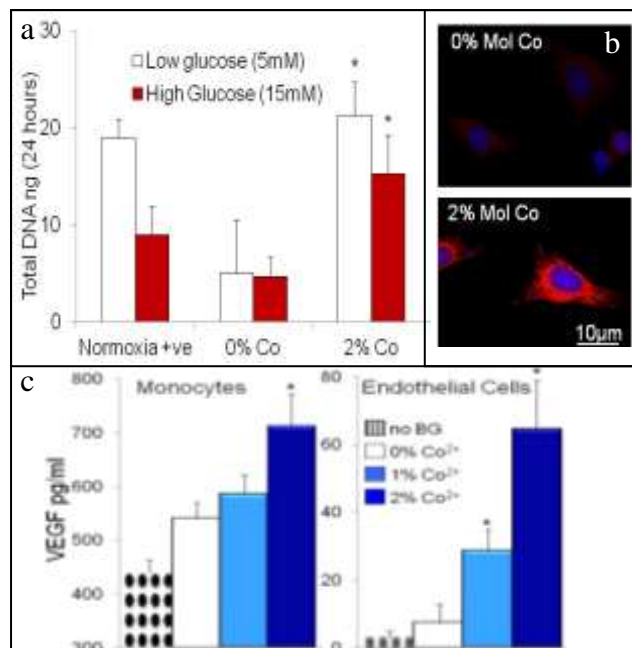

Figure 2. (a) HBG (2% Co^{2+}) increased EC migration in both low and high glucose environments (24hr) (b) HBG increased HIF1 α expression in both cytoplasm and nuclei. (c) HBG caused a concentration dependant increase in the expression of VEGF by M ϕ and ECs after 24 hr culture. * $P < 0.05$ compared to 0%BG

HBG conditioned media activated a number of regenerative process associated with wound repair including, increased cell migration, the increased of angiogenic factors (VEGF and FGF) and also promoting the differentiation of M ϕ and increasing phagocytic activity. Importantly some of these regenerative processes were observed in chronic wound-like conditions (high glucose).

CONCLUSION HBG offers a controllable ion release system that can stabilise HIF1 α and initiate upstream wound repair. Considerable further work is required to develop and translate these promising results into HBG-hydrogel wound healing constructs.

Non-invasive and specific attachment of hernia mesh by click chemistry

R. Vestberg¹, M. Guerin¹, A. Radlovic¹, O. Lefranc¹, S. Ladet¹

¹Covidien Trévoux, France
robert.vestberg@covidien.com

INTRODUCTION

Hernia repair is frequently performed involving mechanical fixation of a surgical mesh that could be associated with chronic pain.

In this concept, a way to mimic the cellular adhesion mechanism in living tissue for fixation of surgical mesh was investigated. Leveraging the click chemistry technology, it would be possible to develop more precise fixation by targeting the specific areas to be attached while preserving sensitive anatomical structures. Moreover by spreading the fixation strength on the entire surface of the mesh, it is expected to reduce local constraints and associated pain. This innovative approach inspired by nature represents a precise and less invasive fixation mean to improve the clinical outcome of patient receiving hernia repair.

EXPERIMENTAL METHODS

Click chemistry¹ is a recent concept which is designed to replicate the physiological molecular interaction. In the click chemistry reaction two reactive entities are linked as a key and lock mechanism. In this work, cell and device surfaces have been activated with the two reactive entities (azide and alkyne) and the cells connected to the device surface using the copper mediated azide-alkyne cycloaddition click reaction (CuAAC).

Figure 1. Schematic of non-invasive fixation of tissue to a medical device surface by click chemistry.

RESULTS AND DISCUSSION

To demonstrate the concept of interaction between living tissue and medical devices, cells with reactive Click entities need to be obtained. Cells were exposed to a manose containing the click reactive entity (azide), which was then expressed on the cell membrane². The expression of the click entity on the cell membrane was verified by attaching a fluorescent molecule (Alexa 488) containing the complementary click reactive entity (alkyne) to link the fluorescent molecule to the cell membrane. Flow cytometry results confirmed a successful functionalization of the cells with high cell viability

Figure 2. Results from flow cytometry.

To demonstrate the specificity of click fixation, activated cells were exposed to a patterned device surfaces. The patterned on the device surface was composed of alkyne substituted chitosan. To characterize the specific cell attachment to the surface, living cells were stained in green (Live/Dead staining).

It was demonstrated that cells could successfully attach only to the activated surface and that an activated devices could be precisely patterned to drive cell specific attachment (bracket area).

Figure 3. Fluorescent microscopy showing that cells can be driven to attach to a predefined part of a surface.

CONCLUSION

This work demonstrated that non-invasive and precise fixation of medical devices could be obtained by click chemistry activation. Click chemistry is a highly specific and versatile concept which can redefine the way we do surgery.

Tubular compressed collagen scaffolds cultured in a novel flow-bioreactor system for ureter/urethra tissue engineering applications

Elif Vardar¹, Eva-Maria Balet¹, Hans Mattias Larsson¹, Jeffrey A. Hubbell¹, and Peter Frey¹

¹Institute of Bioengineering, École Polytechnique Fédérale de Lausanne, Switzerland, elif.vardar@epfl.ch

INTRODUCTION

Urological tissue engineering aims to overcome complications like secondary malignancies, intestinal adhesions, and chronic infections that are linked to classical surgical repair of urinary tract (1). The latest developments in urological tissue engineering have been intended to design novel scaffolds and cell culture techniques for urinary tract reconstruction. The use of bioreactors has brought many significant advantages, such as pre-determined culture conditions that are similar to physiological conditions, to the traditional tissue engineering approaches. In this study, plastically compressed (pc) tubular collagen scaffolds were evaluated under dynamic culture conditions inside a novel flow-bioreactor system imitating the dynamic environment of the ureter. After determining the flow conditions mimicking the best ureteral flow, biological performance of pc tubular collagen scaffolds was evaluated in the flow-bioreactor device.

EXPERIMENTAL METHODS

Scaffolds were prepared by casting a neutralized collagen solution (Rat tail collagen type I, First Link, 2.05 mg/ml) containing primary human bladder smooth muscle cells (hSMC) into tubular moulds. After polymerization, scaffolds were compressed by applying a compressive stress of 5 kPa for 2 min at room temperature. A ureteral flow cycle program was written by using ProgEdit software. Mean luminal pressure values along pc collagen tubes were determined by using a digital manometer, attached to the luminal outlet (Fig. 1). To induce flow, the chamber was connected to a sterile media reservoir via a peristaltic pump (Ismatec).

Figure 1. Schematic representation of the flow-bioreactor system. Inner diameter of silicon tubing “a” is smaller than that of “b” to create a flow resistance.

Burst pressure of pc collagen tubes was determined as connecting the tube to a water column and increasing gradually the hydrostatic pressure until the leak detection. The ultimate tensile strength (UTS), linear modulus (E) values were evaluated by Instron tensile machine. hSMC-seeded pc collagen scaffolds were assessed using AlamarBlue assay for cell proliferation, Live/Dead stain (Live/Dead® Viability/Cytotoxicity Kit for mammalian cells, Invitrogen) for cell viability, and Hematoxylin and Eosin (H&E) staining for cell distribution throughout the scaffolds. Change in gene expression of hSMCs was evaluated by RT-qPCR (Roche). Paraffin embedded sections of cell-seeded

scaffolds will be stained for alpha-smooth muscle actin (α -SMA), smoothelin (SMTN), and human collagen type I (COL1A1). Significant differences between datasets were determined by ANOVA tests.

RESULTS AND DISCUSSION

Around 23 cmH₂O pressure change, a value, which is in the range of ureteral pressure (2), was obtained within pc collagen scaffolds during a pump cycle at 20 rpm (Fig.2).

Figure 2. (A) The pump cycle scheme (B) The maximal pressure values within pc collagen tubes with increasing rpm values, *p < 0.001.

hSMC seeded within tubular pc collagen scaffolds showed a high cell viability up to day 7 and aligned parallel to the flow direction under dynamic conditions (Fig. 3).

Figure 3. Live/Dead® Viability assay. Confocal z-stack images of hSMC seeded pc collagen tubes after 7 days of culture. Arrow shows flow direction.

Characterization of mechanical properties of pc collagen tubes, immunohistochemistry and gene expression studies are currently on-going.

CONCLUSION

Preliminary results show that our flow-bioreactor system provides dynamic conditions, which are similar to the physiological environment of the native ureter. Therefore pc collagen tubes, matured in this flow-bioreactor system, are a quite promising biomaterial for urological tissue engineering applications.

INTRODUCTION

Angioplasty is a technique in treatment for opening blockage in blood vessels. There are different techniques for the operation of opening blockage in vessels. Using angioplasty balloon is limited as 2-3 percent of patients need to open heart surgery and blockage in vessels would be backed in 30-50 percent of patients. At first, balloon was utilized only for opening coronary arteries, but while time passed problems like intimal dissection or recoil or being again blocked were appeared which sometimes made catastrophe. With the probability of early reclogging after some hours or days, scientist have invented stents to reduce the problem of reclogging coronary arteries after angioplasty. In 1987, Sigwart had reported that they implanted stent successfully. Stent is a small mesh tube that made from metal that open artery and would be remain inside it forever.

EXPERIMENTAL METHODS

Stainless steel thin wires 316 in 0.3 mm diameter has been employed in the research. Wire diameter is determining through exited stent from patient body. Polymer polexi sheets in 2 mm thickness were utilized to build a frame for shaping stent wire; the sheets had been cut with laser and five of them connected together for building a jaw frame. laser cutting was selected for constructing cardiovascular stent as it is commercial and have many advantages. with the country possibilities, it is impossible to build a cylinder with thickness about microns through extrusion; Stainless steel wire stent was selected which has lower cost price and better characteristics in this context. The stent was exited from one of the patient's coronary arteries that had been made from welded thin wires to each other. Thus, thin wire welding method which needs lower facilities, was selected in this project. For forming stainless steel wires in shape of stent, jaw like frames have been utilized that made from polymer polexi. Polymer sheets have cut by laser in model of stent and in 2 mm thickness. The machine conducts accurately the cuts through computer software. Design of stent was drawn by Corel Graphic Program exactly like the model and dimensions of the stent that was exited from the body. It was set to use laser spot welding like similar commercial samples for connecting each of the formed wires. Tensile test, metallographic testing of welding locations and SEM scanning electron microscopy have been done on laser welded stainless steel wires to consider laser welding. Another way has been considered to connect the formed wires. In the project,

stainless steel wires which formed with polymer frame were welded together through thermal soldering iron that is efficient in very fine electric board welding.

RESULTS AND DISCUSSION

Results of micro hardness testing on wires provided in dimensions of stent.

Mean of transverse micro hardness (Vickers)	Mean of longitudinal micro hardness (Vickers)
241/3	240/7

Results of micro hardness testing on stent wires which went away from the patient body

Mean of longitudinal micro hardness (Vickers)
169/3

Results of tensile testing have shown that strength of stent welding about 0.725 Mpa is more than strength of laser welding under test. A significant notice in tensile testing is that each of the connections were broken from welding point which explained welded point that is under test would not be weaker than stent laser welding that went away from the patient's body. Metallography images were taken from stent welding point and part of wire which did not weld, the structure of welding and not welding part is similar, as lower thickness of wires in stents laser welding has reduced welding time and laser temperature and then cannot make any changes in combination and structure. Wires laser welding is conducted through a programmed machine in constructing commercial stents which changes will not be created in the structure. Therefore, time and laser beam energy must be set to achieve appropriate strength in such cases and finally obtain the best condition for receiving the best strength.

CONCLUSION

SEM scanning electron microscopy presented a relative uniform welding with no crack. time and laser beam energy must be set to achieve appropriate strength in such cases and finally obtain the best condition for receiving the best strength. Results of micro hardness testing on wires provided in dimensions of stent and wires which went away from the patient body showed that these wires are appropriate for making stent in this project.

Towards an Implantable Bioreactor: Synthesis and Surface Modification Strategy for a Soft Tissue Engineered Elastomer

D-E. Mogosanu^{1,2}, J. Vanfleteren², P. Dubruel¹

¹Polymer Chemistry and Biomaterials Research Group, Ghent University, Belgium

²Center for Microsystems Technology, Ghent University, Belgium, dianaelena.mogosanu@ugent.be

INTRODUCTION

For future construction of implantable tissue structures, the development of 3D biodegradable fluidic microsystems is necessary. In the last decade, poly (glycerol-sebacate) (PGS) has become one of the most studied elastomers for biomedical applications due to its biocompatibility and biodegradability. The first reported synthesis involved a 2 day reaction, followed by pre-polymer crosslinking¹. The goal of the current work is to overcome the common limitations of the conventional synthesis strategy that requires a long reaction time. We report a route that reduces by 30-fold the total synthesis time of PGS and a surface modification strategy that enhances the hydrophilicity as well as the cell-interactivity. Moreover, we are developing a unique technology for biodegradable 3D microsystems that can sustain cell co-cultures. This technology can be easily transferred to all poly(polyol sebacate)s present in literature.

EXPERIMENTAL METHODS

Synthesis and fabrication of PGS films

Equimolar quantities of reagents (Sigma-Aldrich) were mixed in a reactor at high temperatures for different reaction times. Films were fabricated by melting the pre-polymer on a polysaccharide coated mold and curing in a vacuum oven at 150°C.

Functionalization of PGS films

PGS films were functionalized via a graft polymerization procedure, followed by the attachment of gelatin to the surface. Both PGS and PGS-Gelatin films were analyzed via IR mapping, XPS, AFM, SCA and microscopy techniques.

Bioreactor development

Patterned silicon wafers were processed by standard lithographic processes. The micro-pattern (50-100 μm width and 100 μm height) was transferred to PGS. The patterned PGS layers were aligned and bonded. Porous membranes were inserted in between patterned layers in order to create proper conditions for cell co-culture.

RESULTS AND DISCUSSION

The polycondensation reaction performed via the strategy we report yielded a final yellowish elastomer. The reaction kinetics indicated an optimum synthesis

time of 1.5h, almost 30 times less than the time reported by the classical route¹. Surface modification of the native material is required due to its high hydrophobicity, similar to that of PDMS. Contact angle measurements showed a decrease from 92° for the PGS film to 35° for the gelatin modified PGS film. XPS analyses indicated that PGS-protein films have a similar N/C ratio to that of the pure gelatin. IR mapping showed a complete coverage, while AFM measurements indicated gelatin clusters present on the polymer surface.

Two- and three-layer microfluidic devices were developed in order to design a tissue-engineered organ. As vital organs contain multiple types of cells, we have integrated a porous membrane in the microfluidic device. This strategy would enable not only cell co-culture, but also distribution of nutrients and oxygen.

Figure 1a shows the perfusion test of a microfluidic device, while 1b presents the channels cross-section of a two-layer microfluidic device.

CONCLUSION

PGS was successfully synthesized via a rapid method. The usefulness of this approach has been demonstrated by the 30 times reduction of the conventional synthesis time. As synthetic biomaterials that mimic the ECM have a wide range of biomedical applications, we have also functionalized the polymer with a protein via a chemical immobilization technique. We are currently investigating the adhesion and proliferation of different cell types on the modified polymer surfaces, as well as the development of complex 3D microfluidic systems for cell culture and tissue engineering.

INTRODUCTION

Bone is a living tissue mainly populated with osteoblastic cells (OB), osteoclastic cells (OC) and endothelial cells (EC). Their crosstalk is essential for bone homeostasis and to optimize bone regeneration after biomaterial implantation. Whereas links between OB and OC as well as links between OB and EC are well established, the communication between OC and EC remains unknown¹. Moreover, no tri-culture system from human primary cells has been described in the literature³. In a previous work, a medium allowing the co-culture of OC and EC was established by our team (α MEM/EGM2*). In the present study, the capacity of this medium to be used in an original primary human tri-culture model was investigated. The osteoclastic resorption activity, the osteoblastic and endothelial phenotypes maintenance, and finally the set up of a tri-culture model, were assessed.

EXPERIMENTAL METHODS

Cell culture media: α MEM/EGM2* medium was made of equal volumes of α MEM (alpha Minimum Essential Medium) and EGM2* (Endothelial Growth Medium-2-MicroVascular (EGM2-MV) without ascorbic acid and hydrocortisone which inhibit OC differentiation).

Cell culture models: Mononuclear cells (MNC) were isolated from human umbilical cord blood. OC and EPC were obtained after MNC differentiation with specific cell culture conditions. Endothelial Progenitor Cells (EPC) were used as EC model.

Mesenchymal stem cells were isolated from human bone marrow and differentiated towards OB.

Cell differentiation assays: Osteoclastic resorption activity was assessed on calcium phosphate substrates using differentiated OC from MNC. Resorption lacunae were identified by scanning electron microscopy and quantified by image analysis.

Both in a single culture model and in a co-culture model, OB and EPC were characterized by Alkaline Phosphatase (ALP) staining and immunolabellings of von Willebrand Factor (vWF), CD-31 and VE-cadherin, respectively. Mineralization of extracellular matrix (ECM) was characterized by Von Kossa staining.

In the tri-culture model OB, OC and EPC were cultured both in direct and in indirect contact. In indirect contact conditions, OB and EPC were cultured in a transwell whereas MNC remained on the plastic. OB and OC differentiation was characterized by ALP and Tartrate Resistant Acid Phosphatase stainings, respectively.

Data are presented as means \pm standard error of the mean, with n indicating the number of independent experiments. Differences were assessed by paired Student's t-test and accepted as statistically significant when $p < 0.05$.

RESULTS AND DISCUSSION

In the presence of α MEM/EGM2* medium, osteoclastic resorption activity was not significantly changed with $5286 \mu\text{m}^2 \pm 1150 \mu\text{m}^2$ of resorbed area per substrate compared with $4335 \mu\text{m}^2 \pm 1104 \mu\text{m}^2$ of resorbed area per substrate in the presence of α MEM control medium ($n=6$, $p=0.24$).

Both in the single culture model and in the co-culture model, after 3 and 7 days, immunolabellings of vWF, CD-31 and VE-cadherin were similar for EPC cultured with α MEM/EGM2* compared with EPC cultured with α MEM/EGM2-MV medium (control condition). Similarly, comparable ALP expression as well as ECM mineralization after 10 days, were observed. These data showed that osteoblastic and endothelial phenotypes were preserved in α MEM/EGM2*.

The possibility of culturing the OB, OC and EPC together with the medium (α MEM/EGM2*) was then investigated. Aiming for osteoclast formation in this tri-culture model, OB and OC markers were assessed after 11 days of culture. Both TRAP positive cells and ALP positive cells were observed. However, as previously published³, EPC cannot be detected after more than 7 days of culture in a co-culture system. Interestingly, when the tri-culture was performed in indirect contact, a higher osteoclastogenesis was observed compared with the tri-culture in direct contact. These data suggested that osteoclast formation might be modulated by OB and/or EC direct contact in our model.

CONCLUSION

Results of this study validate the use of α MEM/EGM2* as a medium a) to obtain functional OC after MNC differentiation, b) to preserve osteoblastic and endothelial phenotypes both in mono- and co-cultured models and c) to set up a original tri-cultured model based on human primary OB, OC and EPC. This model is a promising tool both to study bone cell-material interaction and to optimize strategies in bone tissue engineering.

Fabrication of porous titanium scaffolds by stack sintering of microporous titanium spheres produced with centrifugal granulation technology

Hongjie Chen, Xiangdong Zhu, Yujiang Fan, Xingdong Zhang

National Engineering Research Center for Biomaterials, Sichuan University, China, s_mitory@126.com

INTRODUCTION

Titanium (Ti) has been widely used for bone grafts in load-bearing sites. Nevertheless, stress shielding would lead to bone resorption and loosening of the implant. By controlling porosity and pore size distribution, the porous Ti scaffolds could be biomechanically compatible^{1, 2}. In the present study, a simple new approach to fabricating load-bearing porous Ti scaffolds with uniform porous structure, highly controllable pore size and excellent biocompatibility was developed. This scaffold was made by stack sintering of microporous Ti spheres produced with centrifuge granulation of commercial Ti powders. The porous structure, mechanical property and biocompatibility of the fabricated porous Ti scaffolds were investigated.

EXPERIMENTAL METHODS

By centrifuge granulation of commercial Ti powders (38-45 μm , 54-63 μm and 88-97 μm), microporous Ti spheres (500-600 μm , 800-900 μm and 1000-1250 μm) were fabricated. The Ti spheres were then filled into a cylindrical mold, compacted and sintered in a vacuum of 1×10^{-3} Pa at 1300 $^{\circ}\text{C}$ for 2 hours, forming the porous Ti scaffolds, as shown in Table 1. The morphology, pore size distribution and mechanical strength of the scaffolds were respectively assessed. To evaluate biocompatibility of the scaffolds, protein adsorption and cell culture experiments were performed.

RESULTS AND DISCUSSION

The macroscopic appearance and microstructure of the fabricated porous Ti scaffolds are shown in Fig. 1 (a) and (b). By this method, the macropores and micropores size distributions of the Ti scaffolds could be accurately regulated by choosing appropriate size ranges of the primary Ti powders and the secondary Ti spheres. With the increasing size of the primary Ti powders, the average micropores size increased from 6.8 to 14.0 μm . And with the increasing size of the secondary Ti spheres, the average macropores size of increased from 121.6 to 363.5 μm , as shown in Fig. 1 (c). With increasing size of the Ti spheres, the compressive strength of the scaffolds decreased from 108.9 to 83.4 MPa, as shown in Fig. 1 (d), but the Young's modulus had only a little decrease from 3.0 to 2.7 GPa. The results of serum proteins adsorption on the surface treated scaffolds was measured, and shown that there was more serum proteins adsorption on the scaffolds made from the microporous Ti spheres than that from the dense Ti beads. After 3 days of culture, a large number of MSCs were tightly attached to the rough and convex surface of the macropores, and part of them had polygonal or fibrous shape, meaning that the scaffolds could allow better growth and proliferation of the cells.

Table 1 Specification of porous Ti samples.

Designation	Ti powders/ μm	Ti spheres/ μm
Ti-600	-	600 (Ti beads)
Ti-600/54	54-63	500-600
Ti-900/38	38-45	800-900
Ti-900/54	54-63	800-900
Ti-900/88	88-97	800-900
Ti-1250/54	54-63	1000-1250

Fig. 1 (a) Digital photos of the scaffolds from different Ti spheres; (b) SEM images ($\times 200$) of the scaffold from the Ti spheres; (c) Pore size distribution of the porous Ti scaffolds influenced of the Ti spheres; (d) Typical compressive stress-strain curves of the Ti scaffolds.

CONCLUSION

This work developed a simple new method, i.e. stack sintering of microporous Ti spheres produced with centrifuge granulation technology, to fabricate porous Ti scaffolds with uniform porous structure. The micropores (6.8-14.0 μm) and macropores (121.6-363.5 μm) of the scaffolds could be accurately regulated by choosing appropriate size ranges of the Ti powders and the Ti spheres. The compressive strength (83.4-108.9 MPa) was high enough for use as load-bearing scaffolds. Besides, the scaffolds were favourable for adsorption of serum proteins, and the rough and convex surface promoted the attachment and growth of MSCs. In conclusion, the porous Ti scaffolds developed in the present study could have better potential to be used as bioactive scaffolds or coatings for the repair of bone defects in load-bearing sites.

⁴imds, Logan, UT, Roy.bloebaum@hsc.utah.edu

INTRODUCTION

Extensive research began in the 1980s to develop biomaterials that would assure skeletal attachment in cementless total joint replacement (TJR)¹. Despite these efforts, early mechanical loosening, unrelated to wear, continues to be reported in clinical literature.

The acetabular component in the hip replacement and tibial and femoral components in the knee replacement are the most vulnerable to early mechanical loosening². One possible explanation is that the cancellous bone has less potential for osteointegration. Despite this knowledge, many investigators still use the transcortical model to screen new porous coatings. This study highlights the importance of using the appropriate and clinically predictive model to screen new biomaterials intended for cementless TJR.

The objective was to use the transcortical and intracondylar locations of the large animal model to determine the differences in bone responses to two different materials with two different shapes. The null hypothesis was that there would be no difference in the bone responses between the two materials and the two geometric dimensions.

EXPERIMENTAL METHODS

A weight-bearing ovine model was used because it has translated successful skeletal attachment clinically²⁻⁵. Porous-coated titanium (Ti) plugs (Thortex Inc., Portland, OR, TJO Inc., Salt Lake City, UT) were used as the investigative material (control) because they provide successful attachment in TJR. Coprolites, or dinosaur poop (DP), were used to establish a dramatic understanding that even this unique material (that would never be used in TJR) could demonstrate skeletal attachment at the transcortical location.

Figure 1:

Figure 1 displays the proud DP plug (left), proud Ti plug (middle), and inset Ti plug (right).

Ten sheep were used. Two 8 mm-diameter holes were drilled into the right lateral femoral condyle (intracondylar model) as well as into the diaphysis of the tibia (transcortical model). Four implants were placed within each sheep: one DP and one Ti in the condyle and one DP and one Ti in the tibia. Five sheep received inset plugs in both locations and five sheep received proud plugs in both locations.

The proud plugs were implanted in a “press-fit” fashion into the prepared hole. The inset plugs were inserted

leaving an inner 500-μm gap between the implant surfaces and the drill track. Literature has demonstrated that a distance greater than 100 μm results in fibrous encapsulation in cancellous bone¹¹. Sheep were euthanized at 12 weeks. Radiographic and histological assessment was performed.

RESULTS AND DISCUSSION

Histological data showed fibrous tissue around the DP plugs in all locations and dimensions. Bone traversed the 500-μm gap in the transcortical location but not in the intracondylar location. The Ti inset plugs showed fibrous tissue at the intracondylar site while the Ti proud plugs achieved bone attachment at both sites.

Table 1:

Material	Transcortical	Intracondylar	P-value
Ti	19.73%	62.51%	0.0001
DP	16.95%	46.22%	0.0013

Table 1 displays the average bone formation in the periprosthetic region of the inset plugs.

Table 2:

Material	Transcortical	Intracondylar	P-value
Ti	43.37%	3.10%	0.0094

Table 2 displays the average bone ingrowth into the inset Ti porous coating.

The results highlight the false positive nature of the transcortical model due to its native fracture healing response compared to the more limited healing capacity of cancellous bone. The data validated the intracondylar model for predicting cancellous bone ingrowth for acetabular and total knee components. The location of implantation, geometry, and material type affect skeletal attachment.

CONCLUSION

Intracondylar implantation is the reliable model to assure the performance of any biomaterial intended for cancellous bone attachment. There is no excuse for mechanical loosening of cementless TJR components if proper translational screening is performed.

Incorporation of polyelectrolyte complexes into alginate hydrogels and their effect on the alginate matrix

R. Aston^{1*}, T. Klein², G. Lawrie¹ and L. Grøndahl¹

¹School of Chemistry and Molecular Biosciences, The University of Queensland, Australia, r.aston@uq.edu.au

²The Institute of Health and Biomedical Innovation, Queensland University of Technology, Australia

INTRODUCTION

Polyelectrolyte complexes (PECs) have attracted an increasing interest in biomaterials in recent years; mainly in the area of drug delivery.¹ PECs may also be useful as additives to biomaterial matrices to form composites and tune their mechanical properties. Key requirements for the use of PECs in this application include homogeneous distribution of the PECs throughout the matrix and interfacial interactions between the PEC and the alginate matrix. In this study, we investigated the effects of PECs on the structural and mechanical properties of two types of alginate (ALG) matrices.

EXPERIMENTAL METHODS

PECs prepared using a 1:1 ratio of ALG and chitosan (AC) or 40 % alginate dialdehyde and chitosan (ADC) at pH 4.2 and 7 were characterized using x-ray photoelectron spectroscopy (XPS) and elemental microanalysis. These PECs were then dispersed using 4 % (w/v) loading within ALG hydrogels prepared using both immersion (IM) and internal gelation (IG). Hydrogels were characterized using confocal microscopy, cryogenic scanning electron microscopy (cryo-SEM) and tensile and compressive testing.

RESULTS AND DISCUSSION

XPS analysis confirmed formation of the PECs by a change in the relative ratio of NH_2 to NH_3^+ peaks in the PECs compared to C, corresponding to electrostatic interactions between the NH_3^+ and COO^- . Elemental analysis confirmed 1:1 association between the anionic and cationic polymers within the PECs.

Figure 1. Left: XPS N 1s narrow scan of C. Right: ADC prepared at pH 4.2 Amine, protonated amine and amide peaks were required for the curve fit.

Data shows that no significant change was observed in mechanical properties for the ALG matrix with PEC incorporation.

Table 1. Tensile and compressive modulus (units MPa) of ALG and 4 % PEC loaded IM hydrogels.

Sample	Tensile modulus	Compressive Modulus
ALG	6.5 ± 0.6	5.6 ± 0.7
AC4.2	5.9 ± 0.2	5.3 ± 0.4
ADC4.2	6.4 ± 0.4	5.3 ± 0.5

Cryo-SEM images reveal a challenge in identification of the PECs in the hydrogel materials. Images show a more homogeneous porous structure in the high pressure frozen sample devoid of eutectics and hexagonal ice crystal artefacts present in slush frozen samples.

Figure 2. Cryo-SEM of (a) ADC prepared at pH 4.2, (b) ALG-IG with ADC loading using slush freezing, and (c) ALG-IG using high pressure freezing.

Confocal microscopy showed PEC dispersion.

Figure 3. Confocal microscopy of ALG-IM with labelled (a) AC and (b) ADC.

PECs dispersed throughout the ALG matrix, with no effect on the mechanical properties of IM hydrogels. Investigation into the effects of higher loading is being investigated and will be presented. Investigation into cryo-SEM freezing regimes revealed the advantages of high pressure freezing over slush freezing. However, many imaging and sublimation challenges were encountered using cryo-SEM, and as such, this technique should be used with caution.

CONCLUSION

Dispersed PECs at low loading in ALG-IM hydrogels do not change the mechanical properties of ALG. IM and IG hydrogels have a porous structure identified using an appropriate cryo-SEM freezing and sublimation regime for the material.

INTRODUCTION

Tissue engineering (TE) of meniscus aims to restore the loss of meniscus tissue both anatomically and functionally, by transplanting a substitute that should be able to mimic the properties of native tissue¹. In this study, novel silk fibroin scaffolds² combined with human meniscus fibrochondrocytes were evaluated *in vitro* for their performance as meniscus substitutes.

EXPERIMENTAL METHODS

Silk-based scaffolds (10 and 12 wt%) were produced in the form of discs (4 mm in diameter and ~3 mm in height) by means of combining salt leaching and lyophilization methods. Human meniscus cells (HMC's) were isolated from macroscopically intact human fresh menisci using an enzymatic digestion-based technique and expanded using standard culture conditions. HMC's were then seeded at a cell density of 5×10^4 cells/scaffold and the cell-laden constructs were cultured in static conditions, up to 21d. Viability (Calcein-AM staining), metabolic activity (MTS assay) and proliferation (DNA quantification) were evaluated until 21d of culturing. HMC's adhesion was investigated by scanning electron microscopy (SEM). Expression of typical cell markers was observed by histology, immunocytochemistry and RT-PCR. Dynamic mechanical analyses (DMA) were also performed. Results are presented as mean \pm SEM, independently of the population used.

RESULTS AND DISCUSSION

Fibroblast-like (elongated form) and chondrocyte-like (rounded morphology) cells were observed in culture after HMC's isolation (Figure 1A). Calcein-AM staining showed that HMC's were viable up to 21d after culturing onto the silk-10% (Figure 1B for 7d) and silk-12% scaffolds. SEM analysis revealed that HMC's effectively adhered to scaffold's surface after 7d (Figure 1C). MTS assay (Figure 1D) and DNA quantification (Figure 1E) analysis showed that HMC's were metabolically active and proliferated throughout the period of culturing in both types of scaffolds.

Table 1 shows the influence of seeding HMC's on scaffolds' biomechanical properties studied by DMA analysis. It was observed that the E' value at 1 Hz of the cell-laden constructs increased with culturing time, reaching a maximum after 14d of culturing, *i.e.* $4.22 \pm 1.74 \times 10^5$ Pa and $11.67 \pm 1.10 \times 10^5$ Pa, for silk-10 and silk-12, respectively. Moreover, it was observed significantly higher values for the modulus of the cell-laden constructs when compared to the acellular scaffolds after 7 and 14d of culturing.

Figure 1. Performance of HMC's (A) loaded on silk fibroin scaffolds (10 and 12 wt%); (B) Calcein-AM staining and (C) SEM imaging of HMC's/silk-10% after 7d of culturing; (D) MTS assay ($n=9$); (E) DNA quantification ($n=9$).

Table 1. Storage modulus (E') of the silk scaffolds cultured with HMC's for different periods of culturing. Statistical analysis was performed based on the values obtained at 1 Hz and using a two-way ANOVA followed by Bonferroni's post test ($n=3$; *** $p < 0.001$).

E' ($\times 10^5$ Pa)	1d	3d	7d	14d	21d
Silk-10 + HMC's	1.89 ± 0.71	2.25 ± 1.57	3.32 ± 1.46	4.22 ± 1.74	2.23 ± 1.57
Silk-10 (Control)	2.06 ± 1.18	2.43 ± 0.31	1.75 ± 0.83	2.43 ± 0.71	2.20 ± 1.79
Silk-12 + HMC's	7.31 ± 1.55	7.98 ± 3.32	9.47 ± 1.27	$11.67 \pm 1.10^{***}$	6.94 ± 1.75
Silk-12 (Control)	6.45 ± 2.09	6.14 ± 0.78	5.35 ± 3.22	5.05 ± 1.69	6.31 ± 2.30

CONCLUSION

Silk scaffolds supported HMC's adhesion, proliferation and viability, while improving the biomechanical features of acellular scaffolds, and thus showed great promise for meniscus TE applications.

Design Functionalized Polyesters and Widen the Applicability in Porous Degradable 3D Scaffolds

Anna Finne-Wistrand¹, Jenny Undin¹ and Ann-Christine Albertsson¹

¹Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Sweden, annaf@kth.se

INTRODUCTION

Synthetic biodegradable polymers are widely applied today as 3D scaffold materials in tissue engineering research because their chemical, physical and mechanical properties are predictable and extremely adjustable through variation of monomers, co-polymers, blends and architectures. However, a new generation of biocompatible and degradable synthetic polymers with various physicochemical, functional and biological properties is required to obtain scaffolds which facilitate advanced tissue engineering.

We have functionalized degradable aliphatic polyesters to extend their properties and the utility of this class of materials in biomedical applications. The mechanical and thermal properties of the polymers have been compared and also discussed in relation to their applicability in 3D porous and degradable scaffolds for tissue engineering.

EXPERIMENTAL METHODS

The following polymers have been synthesized and compared:

- Functionalized polyesters from radical ring-opening polymerizations of ketene acetals:

- Functionalized prepolymers from step-growth polymerization, subsequently used in insertion-coordination ring-opening polymerization:

RESULTS AND DISCUSSION

The thermal property and the mechanical property are two crucial parameters to obtain successful scaffolds in for example 3D printing. Poly(ϵ -caprolactone) has successfully been used in 3D printing because of its relatively low melting temperature and its semicrystallinity. The thermal properties for our functionalized polyesters are summarized in Table 1.

Table 1. Thermal properties of functionalized polyesters.

Polymer	T _g ^a (°C)	T _m ^a (°C)
PCL	-54,9	61,8
PMDO	-57	
PCL-PBM	-58,1	60,2
PMTC	-48.3- (-51.2)	
Poly(MTC-co-MDO)	-49.9- (-55.1)	
Poly(MDO-co-GMA)	-14.6 - 23.9	
Poly(MDO-co-VAc)	-50.1 - 17.2	

The first three polymers in Table 1 have the same repeating unit, ϵ -caprolactone, (1) linear semicrystalline PCL (2) branched and amorphous “PCL” and (3) functionalized “PCL”. PCL-PBM has similar thermal characteristics as PCL and the double bonds in PBM enabled cross-linking, which resulted in porous scaffolds with an increased ability to recover after repeated loading.⁵

The three copolymers in the bottom of Table 1 were synthesized by radical ring-opening polymerization, an efficient pathway to vary the hydrophilicity (poly(MTC-co-MDO) and include functional groups (poly(MDO-co-VAc) and poly(MDO-co-GMA)). The acetate groups in poly(MDO-co-VAc) were successfully hydrolysed using an enzyme, forming a degradable polymer with vinyl alcohol repeating units. In comparison, heparin was attached to the epoxy group in GMA. These amorphous copolymers have some advantages during the scaffold forming procedure but there is a challenge to achieve stable 3D constructs.

CONCLUSION

We present ways to design a new generation of biocompatible and degradable synthetic polymers with various physicochemical, functional and biological properties. Doing this, we have the possibility to not only include functionality into the synthetic degradable polymers but also optimize the properties to increase their applicability.

Investigation of the role of shear stress and compression stimuli on cell seeded PCL scaffolds

M. Brunelli, C. M. Perrault, D. Lacroix

INSIGNEO Institute for in silico medicine, Department of Mechanical Engineering, University of Sheffield, UK
mep12mb@sheffield.ac.uk

Introduction

Cell commitment toward a defined phenotype can be regulated by the surrounding environment [1] and the sensed mechanical stimuli [2]. However, the effect on cellular differentiation of resting time applied between consecutive mechanical stimulation is still unclear. The objective of this study is to define a controlled environment able to provide uniform spatial distribution of the stimuli and able to bear and transmit compression load in order to investigate the effect of shear stress or compression stimuli both spaced out with resting periods over mesenchymal stem cells (MSCs) osteogenic differentiation. The focus is first on the mechanical properties of geometrically regular porous polycaprolactone (PCL) scaffolds; secondly on the effect of shear stress on cellular attachment on PCL by developing a microfluidic system and testing it with osteosarcoma cells (MG63); third on the injection of collagen gel embedding MSCs into scaffolds to transmit compression stimuli from the rigid PCL structure to cells and assess their viability in the collagen gel.

Materials and Methods

PCL mechanical properties. The scaffold (3D Biotek) is 5 mm in diameter, 1.5 mm thick and $40.4 \pm 0.3\%$ porous. The relaxation behaviour is tested applying and holding compression ramps at 80 and 110 μm for 6 h. Dynamic analysis are performed applying a 80 μm ramp followed by 30 μm amplitude sinewaves (1, 10, 100 cycles) at 0.5 Hz alternated with 4 h relaxation between each cyclic block.

Perfusion system. Polydimethylsiloxane (PDMS) is molded and cut to shape, drilling holes for scaffolds and tubing. After glass plasma bonding, the system is connected to pumps dispensing a suspension of MG63 cells (10^6 cells/ml) at different velocities (0.01, 0.1, 0.5 mm/s). After 24 h, fluorescence stain is added to assess cellular distribution.

Injection of collagen gel and collagen/MSCs into PCL. Bovine collagen type I (Gibco) solution (2 mg/ml) is injected in PCL applying vacuum for 20 min and samples undergo microCT scans (44 KV, 204 mA). MSCs are added to the collagen solution (125×10^3 cells/ml) and 50 μl of collagen suspension is injected in 7 samples. After 24 h, Presto Blue assay is performed.

Results

Calculating the gradient of the stress/strain curve on 7 PCL samples, the apparent Young Modulus is found to be 6.4 ± 3.0 MPa. PCL compression reached equilibrium after 3.5 and 4.5 h for 80 μm and 110 μm ramps

respectively. Dynamic stimulations showed that 1, 10 cycles or 100 cycles do not alter the equilibrium state as it is reached again immediately after the stimulation.

The perfusion system includes bubble traps and it simultaneously tests three samples (Fig.A). In vitro experiments showed a homogeneous cellular distribution through the scaffold confirming a constant flow for all velocities with the best attachment at 0.5 mm/s (Fig.1B).

Fig. 1: (A) Perfusion chamber; (B) 0.5 mm/s seeding; (C) MicroCT cross-section of collagen injected PCL.

MicroCT scans showed penetration of collagen throughout the scaffold, leading to 96% of pores filled (Fig.2C). After 1 day seeding, MSCs seeded in 7 scaffolds embedded collagen have an average viability of 79% compared to control cells seeded in flask at the same density (3000 cells/cm²).

Discussion and Conclusions

Mechanical tests on PCL confirm its ability in bearing cyclic compression. Further investigation is necessary to ensure that plastic deformation is not occurring. The homogeneous cellular distribution obtained with the microfluidic system indicates a mechanically controlled environment. MicroCT scans and PrestoBlue show that collagen fills pores completely, enhancing cell growth. Future studies related to shear stress and compression stimuli involving the perfusion system and collagen embedded scaffolds will be carried out, focusing in particular on quantification of collagen and mineralized calcium content, and osteogenic genes expression through RT-PCR.

Engineered Dermal Micro-Tissues For Bottom-Up Tissue Engineering And TOC Applications

A. Garziano^{1,2} F. Urciuolo^{1,2} G. Imparato^{1,2} P. Netti^{1,2}

¹University of Naples Federico II, Naples, Italy

²Italian Institute of Technology (iit), Naples, Italy, alessandro.garziano@iit.it

INTRODUCTION

Tissue on chip (TOC) is emerging as the new frontier in high-throughput screening technology in drug assessment and development, nutraceuticals, cosmeceuticals and holds the potential to partially replace animal testing [1]. In this work we realized biological micro-modules that can be used as functional living units for TOC application as well as functional building block for the realization of 3D biological tissue in vitro. We demonstrate that μ TPs evolve over culture time resulting in micro-modules having different morphology, ECM organization, transport properties as well as different response to an external stimulus; in particular we evaluated the capability to respond to UVA exposition.

EXPERIMENTAL METHODS

To realize the μ TPs we loaded in a spinner flask human dermal fibroblast and biodegradable gelatine micro beads. The culture suspension was stirred intermittently at 30 rpm (5 min stirring and 30 min static incubation) for the first 6h post-inoculation for cell adhesion, and then continuously agitated at 30 rpm. The μ TPs were monitored along culture time, we focused our attention on the following parameters: oxygen consumption kinetics, diffusivity coefficient, collagen evolution, fusion rate and contraction of areas. Moreover in order to assess the response of the μ TPs to respond to external stimuli, UVA exposition was induced and cell apoptosis profile and mmp-1 expression were evaluated.

RESULTS AND DISCUSSION

The μ TPs realized are living micro-tissue that evolves with culture time (Fig. 1 e-h). The main feature is that they can partly recapitulate a native tissue because they consist of cells embedded in own ECM (Fig. 1 a-d) they well recapitulate the native tissue because are imbedded in own ECM (figures a-d). By monitoring μ TPs fusion capability by time lapse microscopy we found that the increasing of μ TPs fusion rate corresponds an increase in collagen content (Fig. 2 a) and decrease in oxygen consumption (Fig 2 b). This evidence demonstrates that the cells embedded in their own ECM decrease their oxygen need. In order to evaluate their response to an

external stimulus, we evaluated how they react to UVA irradiation by assessing the following reads out: apoptosis profile, mmp-synthesis (Fig 2 c), ECM organization. Interestingly we observe that also the response to UVA change related to the μ TPs age, highlighting a role of ECM in mediating the cellular response.

Fig.1 collagen evolution of the μ TPs by means of confocal multiphoton microscopy (green nuclei, red phalloidin, grey collagen, 7 days (a,e), 14 days (b,f), 21 days (c,g), 28 days (d,h))

Fig.2 collagen quantification (a), oxygen consumption kinetics (b), mmp-synthesis profile before and after UVA exposition

CONCLUSION

In conclusion, our results show that the μ TPs are living micro tissue elements that evolve their properties during culture time mimicking different status of a native tissue. Main peculiarity of our μ TPs appear to be the endogenous collagen, this feature makes them different from conventional in vitro tissue model and permits testing a large number of drugs and drug combinations in a well-replicate micro-scale human tissues equivalent.

Jet-Sprayed 3D Nanofibrillar Environment Decreases Myofibroblastic Activation

Halima Rabehi¹, Romain Debret¹, Pascal Sommer¹, Dominique Sigaudou-Roussel¹, Jérôme Sohier^{1*}

^{1*}Laboratory of Tissue Biology and Therapeutic Engineering (LBTI), UMR 5305, CNRS, Lyon, France, jerome.sohier@ibcp.fr

INTRODUCTION

Myofibroblastic activation of mesenchymal cells is essential to narrow margins and synthesize abundant extracellular matrix (ECM) during skin wound healing or to remodel heart valves ECM.

If recapitulation of natural repair mechanisms is crucial for functional regeneration of soft tissues, it must conversely be controlled to not resume a pathological behavior similar to fibrosis, which results in impaired functionality in skin repair and stenosis in tissue engineered heart valves¹.

Aside from control through physical (substrate rigidity) or chemical cues (TGF- β 1), we hypothesized here that the three-dimensional (3D) structure of nanofibrillar scaffolds can as well mediate myofibroblastic activation.

To investigate this hypothesis, polymer nanofibrillar scaffolds of very high porosities were seeded with skin fibroblasts and their ability to support cell colonization and growth evaluated. Myofibroblastic activation within the matrices was evaluated by immunofluorescence, western blot and quantitative gene expression over time, and compared to films of the same polymer to determine the role of the 3D environment.

EXPERIMENTAL METHODS

Nanofibrillar structures were obtained by jet-spraying² PCL (MW 80000 g/mol) while PCL films were solvent casted on lab-tek chamber slides. Porosity of cored nanofibrillar discs (1 cm x 0.6 mm) was calculated from polymer density and measured volume. Human primary fibroblasts (PCS 201-010, ATCC) were seeded in triplicates (5.105/disc, 1.104/cm² films) and cultured in Quantum 333 medium (PAA) for up to 20 days. Scanning electron microscopy, histology (DAPI staining), DNA quantification, immunofluorescence and western blot against α -SMA, and qPCR were used to characterize nanofibrillar structures and cell fate.

RESULTS AND DISCUSSION

Jet-spraying allowed the production of homogeneous matrices of high porosity (97%) and median pore sizes (55 μ m), composed of nanofibers in average 600 nm. This specific structure allowed an extensive cellular invasion and proliferation (7 fold increase) over time that bridged the matrices within 10 days (Fig. 1).

Fig. 1. Jet-sprayed PCL matrices (A), cell migration at 10 days (B) and proliferation within the matrices (C).

Interestingly, myofibroblastic activation acquired during cell expansion on 2D polystyrene (TCP) was reduced in PCL 3D matrices, as indicated by the extinction of α -SMA expression from 1 to 5 days. Conversely, fibroblasts on PCL films still showed α -SMA expression after 5 culture days (Fig. 2A). The increase of α -SMA expression on PCL films and the decrease in jet-sprayed matrices were confirmed by western blot while qPCR indicated a strong decrease of β -actin and α -SMA genes expressions after seeding (Fig. 2B).

Fig. 2. α -SMA expression on PCL films and lack of expression in nanofibrillar matrices after 5 days (A); myofibroblastic gene expression over time (B).

Overall, these results show that 2D-activated myofibroblasts can be deactivated by a 3D nanofibrillar environment, through a mechanism not only linked to polymer rigidity as PCL films do not induce a similar phenomenon. Ongoing experiments at protein expression level and using stiffer polystyrene jet-sprayed matrices will further elucidate this mechanism.

CONCLUSION

The prospect to mediate myofibroblastic activation through nanofibrillar environments is important for soft tissue engineering, to prevent the formation of unorganized fibrotic tissues.

Fatty Tissue Equivalents – build up with mature adipocytes in a gelatin hydrogel

Birgit Huber¹, Eva Hoch¹, Günter Tovar^{1,2}, Kirsten Borchers², Petra J. Kluger^{1,2,3}

¹University of Stuttgart, Institute of Interfacial Process Engineering and Plasma Technology IGVP

²Fraunhofer Institute for Interfacial Engineering and Biotechnology IGB, Stuttgart, Germany

³University of Reutlingen, Process Analysis & Technology (PA&T), Reutlingen petra.kluger@igb.fraunhofer.de

INTRODUCTION

Large fatty tissue constructs are urgently needed for clinical applications. They are necessary if the subcutis is damaged or lacking due to high-graded burns, congenital deformities, tumor resection or trauma. To date, no suitable replacement is available; autologous fatty tissue transfer results in a high shrinkage of the tissue¹. Also the use of adipogen differentiated stem cells has not shown the requested long term functionality and differentiation². Our strategy is to build up a subcutis equivalent by using mature adipocytes in a chemically modified gelatin matrix, which allows an easy and fast tissue composition.

EXPERIMENTAL METHODS

For the generation of 3D constructs, bovine gelatin was methacrylated³. Cytotoxicity of methacrylated gelatin and the non-cured and cured photoinitiator lithium acylphosphinate (LAP) was determined. An isolation method for mature adipocytes from human fatty tissue was established. These mature adipocytes were characterized in a 2D culture by comparison to differentiated adipose-derived stem cells (ASCs) regarding cell morphology, size and lipid accumulation. Adipocytes were encapsulated into methacrylated gelatin and cultured for several weeks. The elasticity of the constructs was adapted to that of native fatty tissue which was evaluated performing rheological measurements. Viable cells were detected by staining of lipid droplets with Nile Red, nuclei with Hoechst 33342 and cytoplasm with fluorescein diacetate (FDA). Furthermore, H&E staining and the staining of perilipin A and collagen IV were performed on paraffin sections. Cell functionality was determined by glycerol and leptin release.

RESULTS AND DISCUSSION

Methacrylated gelatin as well as the non-cured and cured photoinitiator LAP showed no cytotoxicity tested with adipocytes. Isolated mature adipocytes showed a different morphology, cell size and lipid accumulation pattern compared to differentiated ASCs. A method for

the encapsulation of mature adipocytes into methacrylated gelatin was successfully established (Figure 1).

Figure 1: Mature adipocytes in a 3D gel. Lipid droplets were stained in red (Nile Red), cytoplasm in green (fluorescein diacetate) and nuclei in blue (Hoechst 33342).

The elasticity of the subcutis equivalents was comparable to that of native fatty tissue which was seen in rheological measurements. Cells stayed viable and functional for up to 14 days, which was shown by FDA staining, glycerol and leptin release as well as perilipin A and collagen IV stainings.

CONCLUSION

We were able to show that human adipocytes are a suitable cell type for buildup 3D subcutis equivalents. Methacrylated gelatin is an excellent matrix due to its biocompatibility and tunable properties. Our long-term goal is the composition of large subcutis constructs supplied by a vascular system.

Development of Photocrosslinkable Hyaluronan Hydrogels with Platelets lysates for Tissue Regeneration

Ricardo Leandro Pires^{1,2}, Pedro S. Babo^{1,2}, Rui L. Reis^{1,2} and Manuela E. Gomes^{1,2}

¹3B's Research Group - Biomaterials, Biodegradables and Biomimetics, University of Minho, Portugal

²ICVS/3B's - PT Government Associate Laboratory, Portugal, pedro.babo@dep.uminho.pt

INTRODUCTION

The research on new biomaterials incorporating biochemical cues and well-defined architectures has opened horizons for the regeneration of complex tissues, such as the periodontium. The use of Platelet Lysates (PLs) have shown to have a great potential for tissue regeneration, as the growth factors (GFs) derived from platelets are involved in essential stages of wound healing and regenerative processes such as chemotaxis, cell proliferation and differentiation¹. Moreover, platelets release numerous cell adhesion molecules (fibrin, fibronectin and vitronectin) that are important for the formation of ECM and for the adhesion and migration of cells. Platelet derived GFs have been studied for tendon, bone, cartilage¹ and periodontium regeneration with promising outcomes². In this work we propose the development of multifunctional photocrosslinkable hyaluronic acid (HA) hydrogels by the incorporation of PL. HA is a glycosaminoglycan copolymer of d-glucuronic acid and N-acetyl-d-glucosamine that is present in connective tissues and plays a role in cellular processes including cell proliferation, morphogenesis, inflammation, and wound repair. The incorporation of PL in methacrylated HA is expected to produce a versatile material that could be crosslinked *in situ*, for the directed delivery of growth factors or cells to stimulate new tissue regeneration. Moreover, being photocrosslinkable, this hydrogel may adapt to diverse defect morphologies and/or be processed with defined topographies, using, for example photolithography technologies.

EXPERIMENTAL METHODS

Platelet concentrates with a cell count of 10^6 mL^{-1} were treated with repeated freezing and thaw cycles to generate PL. Methacrylated-HA (Met-HA) was obtained by reacting HA (1.5-1.8MDa) with methacrylic anhydride in basic conditions (pH 8.5). Photocrosslinkable membranes incorporating PL were produced by dissolving Met-HA in solutions of increasing concentration of PL (0, 50 and 100vol%), and using the photoinitiator Igacure 2959. The viscoelastic properties of the membranes were measured using dynamic mechanical analysis (DMA) equipped with the compressive mode in a hydrated environment, at 37°C. Swelling and degradability of the produced membranes incubated in PBS or hyaluronidase (Hase) was assessed up to 21 days. The release of PL proteins from membranes incubated in PBS was quantified by micro-BCA. Also, the viability and proliferation of human periodontal ligament fibroblasts (hPDLFs) either seeded or encapsulated into the developed membranes was evaluated *in vitro*, envisioning the future possible

application of such materials in the regeneration of periodontal ligament.

RESULTS AND DISCUSSION

It was possible to obtain transparent and flexible photocrosslinkable HA membranes (Fig1A) incorporating different amounts of PL, that can be tailored to different shapes/sizes, depending on the casting conditions used. The incorporation of PL improved the viscoelastic properties of the membranes. Moreover, the incorporation of PL enhances the resilience of the membranes to the degradation by Hases (Fig1B).

Figure 1. A- PL-based membranes. B- Degradability of met-HA membranes containing 0, 50 and 100% PL after incubation in Hase (100U/mL); C- Cumulative protein release from membranes containing 0, 50 and 100%; D- PL Proliferation of hPDLFs seeded in membranes incorporating 0, 50 and 100% PL.

The developed membranes were also able to release PL proteins in a sustained manner (Fig1C). hPDLFs either seeded or encapsulated in the photocrosslinkable membranes showed increased metabolic activity as well as cell proliferation over time in culture that was proportional with the incorporation of increasing amounts of PL (Fig1D).

CONCLUSION

This work demonstrates that is possible to obtain versatile photocrosslinkable HA-PLs membranes that provide adequate substrates for hPDLFs attachment and growth while enabling the sustained release of PLs. These results suggest the great potential of these materials as cell and/or autologous growth factors carriers for tissue engineering approaches targeting various tissues, namely the periodontal ligament. Ongoing experiments using micro-lithography techniques are being conducted to define the specific microarchitecture of these materials, as such features are important to direct organized tissue ingrowth for periodontium regeneration applications.

Poly(vinyl alcohol) Physical Hydrogels as Functional, Biodegradable Matrices for Tissue Engineering

Bettina E. B. Jensen¹, Katrine Edlund¹, Anton A. A. Smith¹, Leticia Hosta-Rigau², Brigitte Städler², and Alexander N. Zelikin^{*1,2}

¹*Department of Chemistry, Aarhus University, Denmark

²iNANO Interdisciplinary Nanoscience Centre, Aarhus University, Denmark, bebj@chem.au.dk

INTRODUCTION

For regenerative medical applications, hydrogels have become increasingly attractive as biomaterials owing primarily to their resemblance of soft human tissue. The safety profile and versatility of the synthetic polymer, poly(vinyl alcohol), PVA, have laid the foundation for this material as an outstanding tool in the field of biomaterials science. Regrettably, the development of PVA hydrogels has partially stalled due to shortcomings such as limited opportunities in bioconjugation, poor retention of small molecular cargo, and lack of degradation mechanisms. Herein, we aim to revitalize PVA physical hydrogels by the redesign of PVA. Starting at the molecular level, amine functionality and controlled molecular weights are obtained allowing for optimization of drug loading and conjugation of protein cargo. This allows for the transformation of the hydrogel into a reservoir providing adhering cells with not only (bio)chemical but also physical cues and thus ultimately leading to improved cellular repair.

EXPERIMENTAL METHODS

End group modified PVA¹ was synthesized via RAFT polymerization². For hydrogel production, the microtransfer molding technique was utilized and physical crosslinks were induced via non-cryogenic routes³. Composite physical PVA hydrogels were prepared by incorporation of liposomal sub-compartments into the polymer matrix⁴. Differential interference contrast and fluorescence microscopy techniques were used for qualitative analyses. Flow cytometry was used for cell uptake studies. Cell viability assay was performed to evaluate therapeutic response. All results presented are average of triplicate experiments, reported as mean \pm SD. Student's t-test was used for statistical analysis of data.

RESULTS AND DISCUSSION

Anchoring of liposomal sub-compartments within PVA physical hydrogels was obtained through thiol-disulfide exchange between end group modified PVA and thiocholesterol embedded in the liposome bilayer. It was demonstrated that the amount of encapsulated cargo could be controlled by increasing the concentration of liposomes (Figure 1). Furthermore, liposome retention was evaluated as a function of polymer molecular weight of the matrix and liposome overhang. Lipogels were rendered cell adhesive using PLL or a polydopamine coating (Figure 2).

Figure 1: CLSM images of lipogels with different liposome content. Scale bars: 100 μ m.

The therapeutically active drug, Paclitaxel, was successfully delivered to adhering mammalian cells producing a cytotoxic effect over time.

Figure 2: (A) Uptake of fluorescent cargo. Scale bars: 20 μ m and 100 μ m (inset). Myoblasts adhering to lipogels (B) blended with PLL and (C) PDA coated (red: actin filament; blue: DAPI; green: focal adhesion points). Scale bars: 100 μ m and 20 μ m (insets).

Lastly, conjugation of protein cargo under physiological conditions towards biofunctionalization of hydrogels afforded enzymatically active materials. This presents adhering cells with the localization of active, matrix bound proteins.

CONCLUSION

Cholesterol-assisted conjugation of liposomes to PVA allowed for hydrogel sub-compartments. Therapeutic response mediated by the lipogels illustrates the potential of PVA-based composite hydrogels as drug eluting interfaces suited for surface mediated drug delivery as well as protein immobilization for applications in tissue engineering.

Calcium Concentrations for the Development of New Bioactive Dressings to Improve Skin Wound Healing

Claudia Navarro^{1,2}, Soledad Pérez-Amodio^{1,2}, Josep A. Planell^{1,2,3} and Elisabeth Engel^{1,2,3}

¹Institute for Bioengineering of Catalonia (IBEC), Barcelona, Spain. cnavarro@ibecbarcelona.eu

²CIBER de Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Barcelona, Spain

³Dpt. Materials Science and Metallurgical Engineering, Technical University of Catalonia (UPC), Barcelona, Spain

INTRODUCTION

Extracellular calcium has been proved to affect the healing process of skin injuries. Topical administration of this ion has been demonstrated to benefit the formation of granulation tissue (1). Moreover, usage of calcium-releasing dressings such as calcium alginates improves the healing process (2-3). However, it is still not well understood how Ca^{2+} affects cells *in situ*. The aim of this work is to analyze the effect of extracellular calcium on important aspects of the healing process carried out by dermal fibroblasts. The implication of the calcium-sensing receptor (CaSR) in the cellular events affected by calcium is also studied.

EXPERIMENTAL METHODS

Rat dermal fibroblasts were cultured in the presence of calcium concentrations, ranging from 0 to 7.5mM. Relevant features of the wound healing process were assessed by different *in vitro* assays, including proliferation, cell migration, collagen synthesis and matrix metalloproteinase (MMP) activity. Proliferation was measured by colorimetric immunoassay based on BrdU incorporation during DNA synthesis. Cell migration was quantified by the wound scratch assay. Total collagen synthesis was determined by means of the Sircol™ kit. Finally, MMP2 and MMP9 levels of activity were detected by gelatin zymography.

CaSR expression was assessed by immunofluorescence and Western blot. In order to understand the implication of this receptor in the studied cellular responses, the assays were repeated in the presence of the CaSR agonist gadolinium (Gd^{3+}) at concentrations between 0 and 50 μM .

Each experiment was repeated three times with four replicates. Data were analyzed using ANOVA with Tukey's multiple comparison test.

RESULTS AND DISCUSSION

Proliferation was enhanced with 3.5 and 5mM Ca^{2+} . *In vitro* wound closure was increased using 2.5mM Ca^{2+} , indicating a faster migration of the cells at this concentration. In addition, 5mM of Ca^{2+} showed higher levels of MMP activity and collagen synthesis (Fig. A and B). CaSR was observed to be located in the plasma membrane. Two bands between 250 and 150kDa, corresponding to the dimmer and single form of the receptor, were observed by Western blot. Concentrations of Gd^{3+} between 25 and 50 μM induced proliferation, collagen synthesis and MMP activity in a

similar fashion as Ca^{2+} . Fibroblast migration seemed not to be affected by Gd^{3+} .

The finding that Gd^{3+} induces similar cellular responses as Ca^{2+} in proliferation, collagen synthesis and MMP activity suggests that the CaSR may mediate these calcium-induced cellular events.

CONCLUSION

This study demonstrates that extracellular calcium affects important aspects of the healing process. Assays with other calcimimetics (Mg^{2+} , Sr^{2+} , Zn^{2+} , Calindol, NPS R-568) and negative allosteric modulators of the CaSR (NPS 2143, Calhex 231) are currently in progress. These will provide insight into the implication of the CaSR upon calcium stimulation.

A better understanding of how dermal fibroblasts respond to calcium and the range of concentrations in which it affects may lead to a wiser design of novel bioactive dressings for skin wound healing.

INTRODUCTION

Hemostatic agents are obtained from various biomaterials and sources, and have a long history in human use. Recent development trends in hemostatic agents are self-adhering pads¹⁻³. Those described in the literature usually are combinations of two or more materials of different functions. Here we present a novel “advanced” pad consisting of a NHS-PEG coated collagen pad (PCC). The PEG provides the means to rapidly affix PCC to a wound by crosslinking the collagen pad with blood and tissue proteins. Since blood is not the only fluid present during surgery the first aim of this study was to examine the impact different body fluids can have on the burst pressure of PCC. The second aim of the study was to examine the swelling properties of PCC since PEG-based materials are well known to swell⁴.

EXPERIMENTAL METHODS

Swell Profile:

PCC was placed into polystyrene plates filled with citrated human plasma. A weight of 227 g was placed on a section of each PCC to simulate application pressure by the surgeon. The rest of PCC was left uncompressed. The weight was removed after 1 min or 5 min and the samples were allowed to freely swell for up to 24 hours. The thickness, length, and width of the compressed and uncompressed areas were measured with a caliper at various time-points.

Burst Pressure Model

A burst pressure system similar to those previously described was used⁴. A 4 mm punch biopsy was made in the center of a sausage casing. The sausage casing was wetted with pure porcine blood or 33% and 67% mixtures of porcine blood with various other body fluids. PCC, or collagen pad without PEG coating (control), were placed over the punch biopsy hole and approximated for 2 min with dry gauze and a 200 g weight. After removing the gauze and weight, the treated sausage casing was mounted on a pressure chamber filled with citrated porcine blood. Pressure was applied at a constant rate and the maximum pressure until leakage recorded.

RESULTS AND DISCUSSION

Swelling basically was completed after 1 hour and no substantial swelling took place afterwards. Most of the swelling was observed in thickness due to the formation of a PEG hydrogel with plasma proteins. When compressed, swelling was greatly reduced—very likely—due to crosslinking of the collagen by NHS-PEG. Minor swelling in length and width was seen confirming that most of the swelling is due to the PEG

component. The calculated maximal total swelling for PCC was 65%. PEG-based biomaterials are known to swell >300% and this can lead to serious surgical complications⁴⁻⁶. While PCCs swelling properties are favourable, care must be taken to avoid placement in small spaces.

Addition of saline, urine, and cerebral spine fluid to blood up to a ratio of 2:1 did not significantly influence burst strength of PCC. Addition of lymph did not impact burst pressure at any concentration. In fact, very similar burst pressures were measured for blood and pure lymph fluid. Addition of bile to blood at all tested concentrations reduced burst pressure by approximately 1/3. Nevertheless, all measured values for any of the fluids were well above clinically relevant pressures⁷⁻⁹. In contrast, burst pressure values measured with the non-coated collagen pad were much lower with all tested fluids. This data indicates that as long as some blood is present PCC will adhere to tissue in the presence of the tested fluids.

CONCLUSION

In this study, we evaluated the swell and burst pressure properties of a PEG-coated collagen pad (PCC). PCC had a calculated maximum total swell volume of 65%, which is less than described for other PEG-based materials. PCC maintained burst pressures two times that of clinically relevant pressures. This makes PCC a promising material for various clinical applications.

A Pilot Renal Artery Embolization Study: Evaluation of “Imageable” Embolic Microspheres using Hybrid (Landrace Yorkshire) Farm Pigs

Sharon Kehoe¹, Robert Abraham^{1,2,3}, Charles Daly¹, Daniel Boyd^{1,2,3}

¹*ABK Biomedical Inc. 1344 Summer Street Suite 212 Halifax NS Canada, s.kehoe@abkbiomedical.com

³Department of Diagnostic Imaging and Interventional Radiology, QE II Health Sciences Centre, Halifax NS, Canada

INTRODUCTION

Embolization using microspheres has emerged as a highly effective technique in the treatment of arteriovenous malformations and hypervascularized tumors. Radiopaque microspheres eliminate the need for contrast media and allows the interventional radiologist (IR) to directly monitor the spatial distribution and embolization effectiveness of the agents during the procedure¹. Using conventional imaging (*intraprocedural fluoroscopy and computed tomography, CT*) and histopathological techniques, imageable embolic microspheres were characterized in a pilot study for their *in vivo* spatial distribution and artifact potential during and after transcatheter embolization.

EXPERIMENTAL METHODS

Materials: Imageable embolic microspheres were synthesized from a multicomponent bioglass as per Kehoe et. al.² in particle size distributions of 40-150µm, 150-300µm and 300-500µm. The control article for implantation purposes was the commercial embolic agent ‘Embosphere’ (Merit Medical, Lot No. X415836-5) of particle size distribution 300-500µm.

Methods: Healthy hybrid farm pigs (*species sus scrofa*), mean weight 55.5kg, received unilateral or bilateral renal artery (RA) embolization with material allocation per Table 1. The pilot study received ethical approval from the Comité institutionnel de protection des animaux d’AccelLAB and was in full compliance with the Canadian Council on Animal Care regulations (CCAC).

Table 1: Test and Control Article Allocation.

Pig	Embolization	Pole	Left RA	Right RA
1	Bilateral	Main	300-500µm	300-500µm*
2	Bilateral	Cranial	150-300µm	300-500µm
		Caudal	150-300µm	300-500µm*
3	Unilateral	Cranial	-	40-150µm
		Caudal	-	40-150µm

where * denotes allocation of the Control Article.

An experienced IR performed all embolic procedures and post embolization angiography for each material. After embolization, all arteries in the observation region were qualitatively evaluated for perforation, rupture, non-target embolization and embolization effectiveness. All treated animals were subjected to necropsy. Kidney samples and selected organs were then stored in individually labeled containers filled with neutral buffered formalin. Analysis comprised high-resolution

kidney radiographs (Faxitron MX-20), and micro-CT of whole kidneys to identify (a) embolized areas for histology processing and (b) packing and embolization effectiveness for each material. Whole-body CT was utilized to assess the potential for artifacts arising from the imageable microspheres. Histology specimens were imbedded in MMA, ground to 60µm and H&E stained.

RESULTS AND DISCUSSION

Fig. 1 illustrates the high visibility and spatial distribution of the imageable microspheres within the renal vasculature. Conversely, the spatial distribution of the conventional embolic agent (caudal pole, right hand side) is impossible to assess. Micro-CT analysis indicates that the experimental materials provide for

Fig. 1. Whole body CT (left hand side) and micro-CT of

whole kidney (right hand side).

excellent distribution and packing throughout the renal vasculature for all particle size distributions examined. Histology (Fig. 2) generated in this pilot study indicated that both embolic microspheres were well tolerated, showing no evidence of any inflammatory cells.

Fig. 2. Photomicrographs showing commercial (left hand side) and imageable microspheres (right hand side) through longitudinal tissue sections (H&E; 10X).

CONCLUSION

The imageable microspheres prepared in this study allowed immediate *in vivo* visual monitoring of their spatial distribution and embolization effectiveness inside target organs during the procedure. The safety and efficacy of these imageable microspheres were proven without the use of contrast media.

INTRODUCTION

Bioadhesive systems, i.e. surgical glues, are materials which polymerize rapidly joining tissues in an untraumatic manner. They offer significant advantages compared to traditional sealant techniques, such as sutures; in particular, they are easier to use, non-invasive, offer controllable mechanical resistance and elasticity and they can play an integral part in the healing mechanism of tissue [1]. Surgical glues have several applications such as tissue adhesion; in particular they strengthen and reinforce fragile tissues by tissue adherence, wound healing, sealing of body fluids in surgery, acute aortic dissection and surgery pulmonary parenchymal lesions.

The current surgical adhesive are generally based on fibrin, cyanoacrylates, polyethylene glycol (PEG) or albumin but they show some drawbacks such as the risks of transmission of viral diseases and toxicity of degradation products. The aim of this work was to propose a novel surgical glue based on a fermentation derived human albumin, that allows to overcome the problems related to the traditional glues, and of using 1-Ethyl-(3-dimethylaminopropyl) carbodiimide (EDC) as crosslinking agent in alternative to glutaraldehyde (GA). In particular we optimized the properties of the novel albumin based glue by studying how quick and how good the adhesion of crosslinked albumin (CL-albumin) is to different substrates (biological and no biological) as function of albumin concentration (AC), crosslinking degree (CD) and crosslinker type (CT).

To this aim mechanical, chemical, adhesive and biological properties of this novel glue were evaluated.

EXPERIMENTAL METHODS

The novel surgical glues were obtained by crosslinking recombinant human albumin (Novozymes Biopharma) with two different crosslinkers (EDC and GA), considering different CD and AC.

The rheological properties were evaluated by means of rotational rheometer (Gemini, Bohlin Instruments, UK). In particular the glues have been subjected to periodic oscillation in a dynamic experiment (Small amplitude frequency sweep tests) to evaluate the dependence of viscoelastic properties, i.e. the elastic and viscous moduli, G' and G'' , upon frequency.

To investigate how quick the adhesion of the albumin is on different substrates (pig skin, high density polyethylene, HDPE), it was necessary to find the crosslinking reaction rate of the CL-albumin. To do this the variation of G' , with the time, at a fixed frequency, was evaluated.

The crosslinked albumin samples (CL-albumin) were characterized in terms of their mechanical and adhesive properties, using an Instron Machine (mod.4204). A commercial glue was used as control.

Biological tests were performed on CL-albumin systems in order to determine the biocompatibility of these materials with natural tissues. Human fibroblast cell line were seeded on glues and tested with the Alamar Blue assay direct cytotoxicity evaluation, while PicoGreen assay was performed to evaluate cells proliferation.

RESULTS AND DISCUSSION

The results from rheological characterization of the albumin based glues show a predominant elastic behaviour, typical of a “strong gel”. The increase of AC and CD leads to an increase of elastic properties. Also from mechanical tests it was demonstrated that the maximum stress values increase by increasing AC and CD. Albumin based samples prepared using GA reach lower maximum stress values and lower deformation at break compared to EDC based gel.

From the variation of the elastic modulus upon the time it show that the maximum values of G' and G'' are achieved after 300 seconds and after 100 seconds the moduli are the 80% of the maximum value.

With regards to the adhesion tests on both biological and synthetic substrates, it was demonstrated that the increase of AC and CD has a positive effect on the adhesion strength of the glue.

Moreover the rheological, mechanical and adhesive properties of these novel glues seem to be as good or improved compared to the commercial products, even considering a lower AC and CD. Finally, the results of biological tests demonstrated that CL-albumin systems have no toxic effect on cell viability and proliferation.

CONCLUSION

Biocompatible surgical glues based on an animal-free recombinant human albumin, thereby reducing the risks of transmission of viral diseases were produced and their properties were optimized. Mechanical, rheological, chemical and biological characterization was performed and we demonstrated that these novel glues show improved properties and may have potential in bioadhesive applications.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a bacteria that infects half of the world population¹ and its persistent infection is associated with development of gastric carcinoma. Standard antibiotic treatment is fallible in ~20% of the cases², therefore alternative strategies urge. *H. pylori* blood group antigen binding adhesin (BabA) recognizes Lewis b (Leb) and H-type 1 and sialic acid binding adhesin (SabA) binds sialyl-Lewis a (sLea) and sialyl-Lewis x (sLex) expressed in gastric mucosa^{3,4}.

This work aims to develop a biomaterial which can be orally administrated, bind *H. pylori* in the stomach, removing them through the gastrointestinal tract.

It has been previously shown that 170 µm chitosan microspheres partially crosslinked with genipin are stable in acidic pH, have mucoadhesive properties, are not cytotoxic, are retained in the stomach of C56BL/6 mice for at least 2h and bind unspecifically different strains of *H. pylori*^{5,6}.

We herein evaluate the capacity of glycan-decorated chitosan microspheres (GlyR-Mic) to bind *H. pylori* through specific glycan-adhesin interactions and compete for bacterial adhesion with mice and human gastric mucosa. Efficacy studies were performed using a BabA+ *H. pylori* strain and Leb-positive gastric mucosa from mice and human gastric sections (in vitro) and from mice fresh stomachs (ex vivo).

EXPERIMENTAL METHODS

Chitosan microspheres (Ch-Mic; d=170µm) were produced and GlyR (Leb or sLex) immobilized by “click chemistry”. Immobilization of Leb and sLex was confirmed by transmission electron microscopy (TEM) after immunogold labeling with 1ary monoclonal Ab (BG6 or KM93) and 2ary immunogold conjugate Ab. Adhesion of FITC-*H. pylori* (17875/Leb strain; BabA+/SabA-) to microspheres (Ch-Mic, Leb-Mic, sLex-Mic and Al) (2h; 37°C; OD600i=0.04) was visualized by confocal microscopy. Competition assays for *H. pylori* adhesion between microspheres and gastric mucosa were performed using two in vitro models and one ex vivo model, all expressing Leb. Regarding in vitro studies, Mic were added before (to test their prevention capacity) or after (to evaluate their removal capacity) the FITC-*H. pylori* incubation with sections of paraffin embedded gastric mucosa from mice and humans. Bacterial adhesion levels were quantified using ImageJ software. An ex vivo model was designed to evaluate the ability of Mic to remove/prevent [³⁵S]-radiolabeled *H. pylori* adhesion to fresh mice gastric mucosa, quantified using a luminescence counter. Statistical analysis was performed using the Welch – ANOVA and T-test

(p<0.01) for results from in-vitro and ex-vivo studies, respectively.

RESULTS AND DISCUSSION

Glycan-adhesin specific *H. pylori* adhesion was confirmed since BabA+/SabA- *H. pylori* strain adhered to Leb-Mic but not to sLex-Mic.

Unlike sLex-Mic, Leb-Mic were able to compete with Leb carbohydrates expressed in all the gastric mucosa models tested using a BabA+ *H. pylori* strain. Moreover, Leb-Mic presented higher bacterial removal and prevention rates than Ch-Mic. Regarding the in vitro model of mice and human gastric mucosa, statistically significant differences were observed for bacteria removal rates of ≅60% and ≅43%, and prevention rates of ≅32% and ≅35% using Leb-Mic, respectively. The ex-vivo model using fresh mice gastric stomach also suggested Leb-Mic ability to both remove (≅65%) and prevent (≅78%) *H. pylori* adhesion from/to these gastric sections.

CONCLUSION

H. pylori adhesion to Leb-Mic is ligand specific, and efficiency studies revealed their increased capacity to compete with mice and human gastric mucosa for *H. pylori* adhesion comparing to chitosan microspheres without glycans. These results highlight the potential of glycan nanoengineered chitosan microspheres as alternative or complementary treatment to *H. pylori* gastric infection.

INTRODUCTION

Cancer is a leading cause of death worldwide closely related with genetics, environment and age. It encompasses more than 200 diseases in which abnormal cells divide without control and are able to invade other tissues. However, many cancers have something in common: their mitochondria are altered, and therefore, the energetic metabolism of cancer cells differs from that of normal cells. Consequently, mitochondria can be considered an interesting target for the development of new chemotherapeutics.

α -tocopheryl succinate (α -TOS) has been described as a mitochondrially targeted anti-cancer compound (mitocan) that selectively induces apoptosis of cancer cells and not of healthy cells in a narrow range of concentrations. However, this compound is highly hydrophobic and therefore, difficult to administrate.

We have patented and described in the last years the synthesis of new monomers based on vitamin E to prepare new microstructured amphiphilic copolymers with pseudo-blocks of *N*-vinyl pyrrolidone (VP, hydrophilic) and a methacrylic derivative of vitamin E (MVE or MTOS, hydrophobic). These copolymers were able to form active surfactant-free nanoparticles (NP) in aqueous solution. Moreover, NP were able encapsulate additional α -TOS maximizing the NP activity in a concentration-dependent manner.

The aims of this study are: (1) to study the mechanism of action of vitamin E-based NP. (2) to compare the activity of vitamin E-based NP on the different tumor cell lines and to correlate these data with the energetic footprint of these cells. A detailed study of the effect of the NP on the oxidative stress, nitrosative stress, apoptosis and expression of significant proteins was carried out for pharynx cancer cells.

EXPERIMENTAL METHODS

Monomers were synthesised as described elsewhere¹. Copolymers were obtained by free radical copolymerization of monomers with very different reactivity ratios and different hydrophilicity ($r_{VP} = 0.12$ and $r_{MTOS} = 1.20$ or $r_{VP} = 0.03$ and $r_{MVE} = 2.2$)¹. Loaded and un-loaded surfactant-free NP were obtained by nanoprecipitation. The copolymer (and α -TOS for loaded NP) was dissolved in dioxane and added dropwise to PBS under magnetic stirring and the resulting opalescent dispersion was dialysed against PBS for 72 hours (MW cut-off = 3500 Da).

Breast adenocarcinoma cells (MCF-7 and MDA-MB-231), colon adenocarcinoma cells (WirD), and pharynx cancer cells (Fadu) were cultured following the instructions of the manufacturer. Cell viability (MTT

assay) in the presence of α -TOS-loaded or un-loaded NP was tested for all the cell lines and compared.

Oxidative stress (DHE), nitrosative stress (anti-nitrotyrosine), apoptosis (annexin-V and caspase 3), expression of EGFR and p53 and levels of EGF and VEGF were evaluated.

RESULTS AND DISCUSSION

Both MTOS and MVE based nanoparticles were active against breast cancer cells (MCF-7, MDA-MB-231), colon cancer cells (WirD) and pharynx cancer cells (Fadu) with little or no harm to epithelial healthy cells (HMEpC). As an example the selective action of Poly(VP-co-MTOS) (90:10) is shown in the Figure. Nanoparticles activity was higher in MCF-7 > MDA-MB-231 > WirD > Fadu, and this was related with the energetic footprint of the cells. The more glycolytic were the cells, the higher the activity of the nanoparticles.

Viability of proliferating endothelial cells (HUVEC) was significantly inhibited with no harm to quiescent endothelial cells.

CONCLUSION

The obtained results indicated that these NP present selective anti-cancer and anti-angiogenic activity. Moreover, their activity is related to the energetic footprint of the cancer cells. Therefore, vitamin-E-based NP can be considered excellent candidates for the treatment of highly glycolytic cancers.

INTRODUCTION

The success of pancreatic islet transplantation for the treatment of Type 1 diabetes is hindered by the implant site, mechanical stress, exposure to high drug and toxin loads, strong inflammatory and immunological reactions occurring during the transplantation procedure of producing insulin cells (β -cells). Early islet loss, mainly due to the lack of engraftment, is a major limitation in this type of transplantation, together with the poor revascularization after cell transplant. To overcome this drawback, the use of biomaterials [1], in particular hydrogels based on natural polymers, to protect pancreatic islets and improve islet function has been increasingly proposed and investigated [2]. This work was aimed at assessing the use of an innovative crosslinked gelatin hydrogel to enhance pancreatic islet viability and functionality for islet transplantation.

EXPERIMENTAL METHODS

Type A gelatin (Sigma Aldrich) was crosslinked by Michael-type addition with methylene-bis-acrylamide (MBA, Sigma Aldrich), according to a patented process [3]. Gelatin hydrogels were then dehydrated or freeze-dried to obtain porous structures. Morphology was observed by Scanning Electron Microscopy (SEM). Swelling and weight loss were evaluated at 37°C in phosphate buffered saline (PBS, pH=7.4). Mechanical properties of the swollen samples were assessed using a dynamic mechanical analyzer in an unconfined cyclic frequency sweep test, evaluating storage (E') and loss (E'') modulus. Human and murine pancreatic islets, isolated as previously described [4], were seeded onto the freeze-dried and dehydrated hydrogels, and allowed to penetrate into the swollen hydrogels. Islet morphology, cell survival and insulin secretion were *in vitro* tested 48h post seeding by immunohistochemical analysis, MTT and glucose challenge test. Islets cultured in standard condition (i.e. TCP) were used as control. Dehydrated hydrogels were implanted in the intraperitoneal space (IP) of C57B1/6 mice up to 3 months to evaluate the *in vivo* tissue interaction. Furthermore, syngeneic islets (800 equivalent islets) encapsulated into the dehydrated hydrogel were implanted in IP of C57B1/6 mice (n=4) up to 2 months, using syngeneic islets cultured free floating as control.

RESULTS AND DISCUSSION

The hydrogels, both dehydrated and freeze-dried, were stable in PBS up to 50 days. The hydrogels exhibited storage modulus values in the range 15 – 60 kPa, observing, as expected, lower E' values for the freeze-dried samples, due to the presence of the pores. Immunohistochemical analysis demonstrated that human and murine islets maintained, into the hydrogel, their native 3D architecture, revealing islet retention

and demonstrating that islets seeded onto the scaffolds retained the architecture of native islets up to 6 days post seeding (Fig. 1). Either for human and murine islets, a higher islet survival was detected using dehydrated hydrogels compared to the freeze-dried ones. In particular, human islets reported also a stimulation index value higher than that obtained for islets seeded onto TCP, used as control.

Fig. 1: Murine pancreatic islets cultured onto the dehydrated hydrogel for (a) 48 hours; (b) 6 days. 20 X magnification.

In vivo, no collagen capsule formation was observed after 3 months of implantation, and the hydrogel did not show any morphological change, demonstrating a good *in vivo* stability (Fig. 2a). Hyperglycemia was reversed in mice with islets seeded on hydrogel at day 48, whereas the control mice slightly reduced blood sugar without reversing the hyperglycemic state. After two months, a glucose tolerance test was performed to examine glucose responsiveness of the islet graft, showing a higher glucose responsiveness in islets transplanted with hydrogel than without (Fig. 2b).

Fig. 2: (a) Dehydrated gelatin hydrogel implanted in IP of C57BL/6 mice after 1 month; (b) metabolic test performed 60 days after transplantation on mice receiving islet cultured onto the hydrogel (grey dot) and free floating (white dot).

CONCLUSION

The crosslinked gelatin hydrogels here proposed allow to maintain *in vitro* the 3D islet architecture. In addition, the hydrogel did not affect human and murine islet survival and functionality during short-term culture, ensuring *in vivo* a suitable microenvironment for pancreatic islet function and survival. This data provide a possible novel pre-clinical strategies for islet transplant, opening the way to a future potential clinical translation in humans.

Long-term Degradation of Electrospun Poly(ϵ -caprolactone) Fibre Yarns *In Vivo*: A 12-month Study

Lucy A Bosworth¹, Richard Wong¹, Marie A O'Brien¹, Jason K Wong², Duncan A McGrouther² and Sarah H Cartmell^{1*}

¹School of Materials, The University of Manchester, UK

²Institute of Inflammation and Repair, The University of Manchester, UK

*sarah.cartmell@manchester.ac.uk

INTRODUCTION

Poly(ϵ -caprolactone) (PCL) is a synthetic, biocompatible and biodegradable material commonly used in biomaterial and tissue engineering applications¹. Despite its slow degradation time (>12 months), there are few published studies that investigate this over the long-term in a biological environment^{2,3}. Electrospun PCL scaffolds are being investigated as a potential repair device for patients with damaged tendons⁴. It is therefore important to determine the degradation profile of these scaffolds *in vivo* and hence ascertain their longevity and performance. This study investigated the changes in molecular weight of electrospun PCL yarns implanted into the tendon of a mouse model over a 12-month period.

EXPERIMENTAL METHODS

PCL (Purac - Purasorb PC12) was dissolved in 1,1,1,3,3,3-hexafluoroisopropanol (HFIP; Sigma) at 10 % w/v and electrospun (20 kV, 1 ml/hr, 20 cm). Yarns were created from the collected electrospun fibres as described in Bosworth *et al*⁴. Sterilised in Ethanol (70-100 % v/v (in distilled H₂O) and washed in Phosphate Buffered Saline solution, yarns were cut to 2 mm lengths and individually implanted into a purpose-made defect in the flexor digitorum longus (FDL) tendons of mice. For degradation comparison, PCL yarns were also implanted into the soleus muscle. Scaffold molecular weight was measured using Gel Permeation Chromatography (GPC) and compared to the virgin PCL (yarns as-spun) for each time-point to provide percentage change. Time-points included, 0, 3, 6, 9 and 12 months. At each time-point, grafts were excised and surrounding tissues were enzymatically digested at 37 °C (Tendon: 0.37 mg/ml Collagenase Type II in Hanks Balanced Salt Solution, Muscle: 0.1 % Pronase in Dulbecco's Modified Eagle Medium), followed by their complete dissolution in Tetrahydrofuran (THF). Data sets were analysed using unpaired t-test ($p < 0.05$).

Visual comparison at these time-points was achieved by histological staining of the tissue (tendon only). Harvested samples were fixed in Zinc for 48 hours and paraffin embedded following processing. Serial sections of 5 μ m were cut and stained with haematoxylin and eosin (H&E).

RESULTS AND DISCUSSION

As expected the PCL grafts degraded within their biological environments over time (Fig.1). Both the number of chains and overall mass of the polymer demonstrated a gradual decrease over the time frame investigated with approximately 50 % loss after 12 months. There was no significant difference in

degradation behaviour between the two graft locations (i.e. tendon or muscle).

Figure 1 – Changes in molecular weight of PCL electrospun yarns implanted in tendon and muscle tissue, where (A) shows number average molecular weight (M_n) and (B) weight average molecular weight (M_w). Data presented as mean \pm SEM; T-test demonstrated no significant difference between tissue sites ($n=4$).

Corresponding histological sections for PCL yarns implanted in the FDL tendon demonstrated their close apposition following implantation (Fig.2). Cell infiltration into the yarn was observed from 3 months onwards and scaffold size appeared to visually decrease with time.

Figure 2 – H&E staining of tendon tissue highlighting PCL grafts *in situ* (indicated by arrows) after, (a) 3, (c) 6, (d) 9 and (e) 12 months (Scale-bar 500 μ m; mag x5).

CONCLUSION

This study demonstrates the long-term degradation of electrospun PCL yarns *in vivo*. Scaffold molecular mass decreased gradually over time and shrinkage was evident. Coupled with cell infiltration suggests these scaffolds could provide an appropriate physical structure and degradation rate to facilitate and support new tendon tissue ingrowth.

*Rachel.auzely@cermav.cnrs.fr

Hyaluronic acid-based hydrogels with independently tunable stiffness and biochemical ligand density have been developed using thiol-ene photo-click chemistry and used to probe primary osteoblast cell responses to the varying biochemical signals.

INTRODUCTION

Engineering artificial scaffolds that enhance cell adhesion and growth in three dimensions is essential to successful bone tissue engineering. However, the fabrication of three-dimensional (3D) tissue scaffolds exhibiting controlled mechanical and biochemical properties as well as well-defined porosity still remains a challenge. Hyaluronic acid (HA) is a natural polysaccharide abundant in biological tissues with excellent potential for constructing synthetic extracellular matrix analogues. Although HA-based hydrogels have been used extensively for tissue engineering, there is still a need to develop HA-based scaffolds with customized functional properties that can provide greater control over the biological response. In this work, we synthesized HA-based hydrogels that offer independent control over biochemical functionality and mechanical rigidity. These biomimetic matrices formed by thiol-ene photo-click chemistry were then used to probe the dependence of pre-osteoblast spreading and proliferation as well as early stage osteogenic differentiation on the ligand functionalization and stiffness in 2D culture.

EXPERIMENTAL METHODS

The HA-based hydrogels were formed by thiol-ene photo-click reactions allowing to control both the density of grafted bioactive molecules (i.e. peptides) and the crosslinking density¹. For a given peptide, several HA derivatives were prepared by varying the density of grafted peptides while maintaining a sufficient amount of alkene groups in order to prepare hydrogels with controlled mechanical properties using poly(ethylene glycol) bis(thiol) (PEG-(SH)₂) as a cross-linker. Carboxymethylcellulose (CMC) was chemically modified according to similar reactions in order to compare the effect of the polysaccharide matrix on the biological response. The grafting of peptides was checked by ¹H NMR spectroscopy. Photorheometric measurements were used to characterize the mechanical properties of the hydrogels as a function of crosslinking density. Swelling experiments were also performed. MC3T3-E1 cells were subsequently seeded on the hydrogels and cultured for 21 days in DMEM supplemented with 10% fetal calf serum. Cell

spreading, proliferation and mineralization were analyzed at culture days 1, 10 and 21.

RESULTS AND DISCUSSION

Successful grafting of bioactive peptides on HA and CMC was confirmed by ¹H NMR spectroscopy which also allowed to determine the degree of substitution (DS, i.e. average number of mole of peptides per repeating unit). This was varied from 3 to 18, depending on the nature of the peptide ligand (GRGD and peptide derived from the bone sialoprotein containing RGD sequence (BSP(RGD))²). Then, using photorheometry for the real-time monitoring of HA crosslinking, we demonstrated the ability to finely control the mechanical properties of the HA hydrogels. For investigating the effect of peptide modification of HA/CMC matrices on the behaviour of primary osteoblasts, we prepared hydrogels having an elasticity modulus (storage modulus, G') of 10000 ± 1000 Pa. Studies of cellular responses to these gels demonstrated that pre-osteoblasts were able to adhere firmly on the HA hydrogels and spread to various degrees onto these substrates depending on the peptide density. HA and CMC gels at optimum peptide densities were then used to assess their ability to stimulate osteoblast proliferation and matrix mineralization. Our findings showed that HA hydrogels suitably modified with peptides BSP(RGD) may be used to favour bone formation.

CONCLUSION

In this work, we established a simple and dependable approach to prepare hyaluronic acid-based hydrogels with controlled stiffness and pre-osteoblast cell recognition properties. The results presented in this study provide a framework for the analysis of interactive biochemical and mechanical signaling on cells cultured in 2D as well as in 3D.

Injectable Biocompatible and Biodegradable pH-Responsive Hollow Particle Gels Containing Poly(acrylic acid): The Effect of Copolymer Composition on Gel Properties

S. Halacheva^{1*}, D. Adlam², T. Freemont², J. Hoyland² and B. Saunders³

^{1*} University of Bolton, Institute for Materials Research and Innovation, Deane Road, Bolton, Greater Manchester, BL3 5AB, U.K., S.Halacheva@bolton.ac.uk

³ University of Manchester, School of Materials, Grosvenor Street, Manchester, M13 9PL, U.K.

INTRODUCTION

Injectable polymer/cell dispersions have emerged as a superior, non-surgical alternative for tissue regeneration.¹ We have previously explored novel types of pH and redox-responsive poly(methyl methacrylate-co-methacrylic acid)- (PMMA-MAA) and poly(ethyl acrylate-co-methacrylic acid) (PEA-MAA)-based hollow particle gels. The gels had micrometer-scale interconnected porosity, high elasticity and ductility values and are potentially suitable for future use in minimally-invasive tissue repair.² Herein we extend considerably our earlier studies with the aim of identifying a system which meets all necessary requirements for soft tissue repair – i.e., high porosity, biocompatibility, biodegradability and adequate mechanical strength. To investigate the effect of tuning hydrophobicity of the copolymer, the glass transition temperature and the pK_a of the particles upon the gel morphology, mechanical properties and performance, we studied the structurally related poly(*n*-butyl acrylate-co-methacrylic acid) (PBA-MAA), poly(methyl acrylate-co-methacrylic acid) (PMA-MAA) and poly(methyl methacrylate-co-acrylic acid) (PMMA-AA) copolymers for gel formation. These systems have been chosen to allow a wide range of structural variation for the constituent pH-responsive copolymers. We have established that MMA is the optimal hydrophobic monomer, whereas the use of various COOH-containing monomers, e.g. MAA and AA, will always induce a pH-triggered physical gelation.³

EXPERIMENTAL METHODS

All copolymers were characterised by ¹H NMR and GPC. Potentiometric titration was conducted using standardized NaOH solutions. Dispersions were deposited on SEM stubs by evaporation at room temperature. Rheology measurements were performed at 25 °C using a TA AR-G2 rheometer and a 250 μm gap with a 20 mm diameter steel plate at 25 °C. DLS measurements were performed on a Malvern Zetasizer Nano ZS90 autocorrelator, at pH values ranging from 6.0 – 10.0. The hydrodynamic diameter (D_h) of the particles was measured at 90°. The particle's volume swelling ratio, Q , was estimated using $Q = (D_h/D_{h(collapse)})^3$, where D_h and $D_{h(collapse)}$ are the hydrodynamic diameters of the particles at a given pH and in the collapsed non-swollen state, respectively.

RESULTS AND DISCUSSION

The physical gels were formed at physiological pH range only from concentrated dispersions of swollen,

hollow, polymer-based PMMA-AA particles crosslinked with either cystamine (CYS) or 3,3'-dithiodipropionic acid dihydrazide (DTP). A linear relationship between particle swelling ratios, gel elasticity and ductility was observed. The PMMA-AA gels with lower AA contents feature lower swelling ratios, mechanical strengths and ductilities. The mechanical properties and performance of the gels were tuneable upon varying the copolymers' compositions and the structure of the crosslinker. Compared to PMMA-AA/CYS, the PMMA-AA/DTP gels were more elastic and ductile. The SEM images of PMMA-AA/DTP gels show highly porous and interconnected structures (Figure 1). Biodegradability of the new gels was tested using glutathione. The rate of network disassembly was found to be strongly dependent upon the gel's structure. The responses of immortalised human chondrocyte cells to contact with the gels were measured by Live/Dead and MTT assay (Figure 1). The gels showed very good biocompatibility, with at least 80% cell viability after 48 hours. Increases in either the crosslinking density or AA content appear to decrease the cell viability.

Figure 1. Redox- and pH-responsive hollow PMMA-AA/DTP particle gel scaffolds.

CONCLUSION

The new pH and redox-responsive PMMA-AA hollow particle gels show good biodegradability and biocompatibility, high interconnected porosity and adequate mechanical strength. Therefore, they constitute a promising prototype injectable gel for tissue repair.

INTRODUCTION

The objective of bioprinting is to assemble living cells or biological materials in 3D for the preparation of tissue constructs. Cell-laden hydrogels termed "bioinks" recapitulate several features of the natural extracellular matrix and allow cell encapsulation in a highly hydrated three-dimensional environment¹.

However, hydrogels used in 3D cell culture substrates are generally mechanically weak and unsuitable to build large volume constructs, specifically in the z-direction. Here, we explore the combination of a cell-laden bioink with a tailor-made cell-free reinforcing gel to fabricate constructs that allow tissue formation whilst providing sufficient mechanical stability.

EXPERIMENTAL METHODS

Hydrogel precursors L-LA-MA and L-CL-MA were prepared by ring opening polymerisation of either D,L-lactide or ϵ -caprolactone, using poly(ethylene glycol)₁₀₁-poly(propylene glycol)₅₆-poly(ethylene glycol)₁₀₁ (trade name Lutrol F127) as macro-initiator, and subsequently methacrylated using methacrylic anhydride in CH_2Cl_2 in the presence of triethylamine. For L-MA, Lutrol F127 was directly methacrylated. Gelatine-methacrylamide (gelMA) was synthesised as described earlier². Disc-shaped specimen (4x2 mm Dxh) were prepared at 10% w/v (gelMA) or 40% w/v (reinforcing gels) in PBS with 0.1% Irgacure 2959 photo-initiator, by exposing to 365 nm UV (2.6 mW/cm²) for 15 min (UVP CL-1000). Compression testing was performed at 0.2 N/min on a 2980 DMA (TA Instruments). Plotting was performed using a BioScaffolder bioprinter at 15°C.

RESULTS AND DISCUSSION

After photo-crosslinking, gelMA gels had a stiffness of 54 kPa. On the contrary, all reinforcing gels were 11x stiffer at 600 ± 67 kPa (Figure 1), and had a tough, rubber-like appearance.

Figure 1: Compressive stiffness of Lutrol F127-based reinforcing gels (40 % w/v) and gelMA bioink (10 % w/v) after photo-initiated crosslinking.

The 3 reinforcing gels showed varying rates of degradation, from fast (L-LA-MA: 68% loss in stiffness over 2 weeks, via slow (L-CL-MA 20% loss in 10 weeks) to no significant loss in stiffness over 10 weeks for L-MA (Figure 2).

Figure 2: *In vitro* degradation of reinforcing gels in at 37°C PBS measured as decay in compressive stiffness over time.

Using the BioScaffolder bioprinter, all reinforcing gels were successfully plotted into porous constructs (L-CL-MA example in Figure 3).

Figure 3: Hydrogel construct plotted using L-CL-MA reinforcing gel (scale bar 5 mm).

Hydrogels that allow cells to develop new tissue are generally mechanically weak. The mechanical properties can be greatly improved by co-printing of a reinforcing scaffold, *e.g.* using thermoplastics³. Here, we present a platform of printable gels, which allows for the co-printing of a biodegradable reinforcing structure without the need for high temperatures.

CONCLUSION

Three printable hydrogels were developed that allow the biofabrication of mechanically favourable constructs, with tailored degradation kinetics.

INTRODUCTION

Non-covalent biopolymer structures that possess simple components with basic biochemical properties similar to the extracellular matrix (ECM) are considered highly promising for various biomedical applications, ranging from drug delivery to 3D cell culture¹. Tailor-made biomaterials with functional complexities can be produced through conjugating different bioactive molecules to simple scaffolds². In this study, we designed a non-covalent assembling system composed of peptide-four-arm-polyethylene glycol (starPEG) conjugates and oligosaccharide³. The hydrogel can be modified without losing its properties as a physical hydrogel or the chemical simplicity.

EXPERIMENTAL METHODS

Bead preparation: Syringes with 4.2 mM peptide-starPEG conjugate and 70 mM 5kDa dextran sulfate were separately prepared and injected in an in house microfluidics system. For cell embedding human neonatal dermal fibroblasts (HDFn) were premixed in KA7-starPEG mixture in full cell culture medium. After life/dead staining with 0.15 μ M fluorescein and 10 μ M propidium iodide images was taken using confocal laser scanning microscopy.

Bead coating: For coating of beads with cells KA7-RGDSP-starPEG conjugate was used and HeLa-actin-GFP cells were incubated with beads. For coating with functionalized peptide-starPEG conjugates, beads were incubated with 1 mg/ml functionalized RA7-starPEG conjugate and washed with PBS afterwards. Coating was imaged using confocal laser scanning microscopy.

RESULTS AND DISCUSSION

We designed and screened minimal peptide motifs whose conjugates with PEG interact with sulfated oligosaccharides (like heparin) to form non-covalent hydrogels (**Figure 1a**). Analysis of structure-function relationship revealed, that peptides containing both basic residues and heparin-induced α -helix formation are important for the assembly process (**Figure 1b**). Namely, the peptides contain repeats of a basic amino acid and alanine ((RA)_n and (KA)_n motifs)³.

Beads were formed by mixing KA7-starPEG conjugate and dextran sulfate in a microfluidic system. Dextran sulfate causes a short gelation time of 10 min. Cells can be embedded with high survival rate (98 \pm 1%, **Figure 2a/b**). Beads with KA7-RGDSP-starPEG can also be coated with cells. Freezing of beads with cells resulted also in high survival. Beads can be further non-covalently modified with proteins or fluorescent labels using RA7-starPEG conjugates (**Figure 2a/c**). Antibodies can be released quickly from the beads.

Figure 1: Structure of hydrogel. **a)** Scheme showing the structure of non-covalent matrix and modifications. **b)** Analysis of heparin-dependent structural changes of peptide by circular dichroism. KA7: (KA)₇, RA7: (RA)₇

Figure 2: Non-covalent hydrogel beads. **a)** Scheme of beads used to embed or coat with cells and applying further non-covalent coatings. **b)** HDFn embedded in hydrogel beads after 7 days (green – alive, red – dead). **c)** Hydrogel beads coated with RA7-starPEG with biotin/streptavidin (Alexa 647 labelled).

Taking these results into account, this system could be used for analysing interaction between cells embedded in and coated around the beads (**Figure 2a**). Furthermore, this peptide-starPEG-oligosaccharide system can be used to **constantly release drugs** over months using the peptides as tags for drugs. Recently, the hydrogel is used to form **thin layers** with different structure and oligosaccharides for easy **surface functionalization**.

CONCLUSION

This novel physical hydrogel system is very versatile. The mildness to cells (as no chemical reaction is involved) and the ease of functionalization make it a biomaterial with many potential applications.

The physical properties of particles dominate cellular uptake and subsequent influences on cell functions

Zhengwei Mao*, Weijun Liu, Pengfei Jiang, Dahai Yu, Xiangyan Zhou, Changyou Gao*

MOE Key Laboratory of Macromolecular Synthesis and Functionalization, Department of Polymer Science and Engineering, Zhejiang University, Hangzhou 310027, China. zwmao@zju.edu.cn, cygao@mail.hz.zj.cn

INTRODUCTION

With the rapid development of nanotechnology, many kinds of nanoparticles have been and are being used in biological and medical fields of industry and scientific researches. Therefore, it would be of paramount importance to understand the influence of particles' physiochemical properties such as size, surface charge and stiffness on the interactions with cells, the smallest building blocks of tissues and organs, in terms of cellular uptake process and mechanism, localization inside cells, and the subsequent influences on cell viability, functions, and phenotypes. On one hand, this kind of study will provide design criteria of particles, which can have better functions in biological applications such as intracellular drug delivery. On the other hand, the impact of particles on cell toxicity and functions will be evaluated to address the safety issue. In this paper, we will give an example of the stiffness of particles that dominates the cell uptake and cell functions.

EXPERIMENTAL METHODS

Four types of poly(2-hydroxyethyl methacrylate) (HEMA) hydrogel particles with different amounts of crosslinking agent, N,N'-methylene-bis-acrylamide (BIS), and thereby compressive modulus were synthesized by an emulsion-precipitation polymerization. The physiochemical properties of the particles in different environment were characterized in terms of size, surface charge, morphology, stiffness and protein adsorption via dynamic light scattering (DLS), transmission electron microscopy (TEM), mechanical tester and bicinchoninic acid (BCA) protein assay. The cellular uptake process of the nanoparticles, including the internalization amount, uptake pathway and intracellular distribution were qualitatively and quantitatively studied. The cytotoxicity of the nanoparticles were studied in terms of cell viability, morphology and cytoskeleton organization, cell adhesion and migration.

RESULTS AND DISCUSSION

All of the particles had a diameter of 800nm in water. Adsorption of proteins (35 mg/g particles) occurred on all the particles, leading to a slightly increase of zeta potential from -20 mV (in water) to -5 mV (in serum containing medium). The softer particles were internalized by HepG2 cells at a faster rate and larger amount than the stiffer ones. Cellular uptake mechanisms were clarified by the addition of inhibitors to specific endocytosis pathways. All the hydrogel particles were internalized by an energy-dependent mechanism. However, uptake of the particles with different modulus follows different mechanisms: the softer particles are mainly internalized via macropinocytosis, whereas the stiffer ones are largely endocytosized via caveolae- and clathrin-mediated

endocytosis as well as macropinocytosis pathways. Uptake of all types of the particles did not cause an apparent decrease of cell viability and alteration of cell morphology, but changed the cytoskeleton organization to some extent. The cell adhesion and migration ability was significantly affected, especially after uptake of the stiffer particles.

Figure 1. Cell adhesion percentage after the cells were pre-cultured with 50 μ g/mL hydrogel particles of different crosslinking degrees, respectively. The data were normalized to those of the particle-free controls. Asterisk indicates significant difference at $p < 0.05$ level, and # indicates insignificant difference at $p > 0.05$ level.

Conclusions: The present study discloses that the stiffness of hydrogel particles influences their cellular uptake amount, rate, and entry routes. Our results suggest that the mechanical properties of particles are an important factor that control cellular response, and should be carefully considered in designing versatile delivery vehicles and other carriers for biomedical applications.

INTRODUCTION

SiRNA has already been widely used in basic science as a method to study the functions of genes and it may provide an alternative therapeutic promise to novel therapies in the future. However, before siRNA can achieve widespread clinical use, significant development must be made in the techniques of siRNA delivery that not only to improve efficiency of targeted delivery but also to protect siRNA from degradation by nuclease. The most studied carrier systems are virus-based, liposome-based and polymer-based delivery systems. Due to the safety concerns raised by virus-based systems and the relatively low transfection efficiency of liposome-based systems, polymer nanoparticles and microspheres have been developed. Polymer microspheres have the capacity to encapsulate large amounts of siRNA, allow co-delivery of multiple therapeutics, can be surface-modified to improve stability, and they also can offer the ability of controlled-release though the degradation of the polymers. The synthetic biodegradable polymers, polylactic acid (PLA) and polylactic-co-glycolic acid (PLGA), are versatile materials able to provide controlled-release and targeted delivery. Polymer microspheres can be applied to target synovial macrophages, utilising the host defence and the process of phagocytosis.

EXPERIMENTAL METHODS

Two fluorescein isothiocyanate-dextrans FD4 (Mw=3,000-5,000) and FD10s (Mw=10,000) were used as model molecules for siRNA. The FD4 and FD10s loaded PLGA microspheres were prepared using the water-in-oil-in-water (W1/O/W2) solvent-evaporation technique. The diameters of the microspheres were adjusted by the speed of stirring and the concentration of the PLGA solution. The degradation of PLGA microspheres and the model molecules release were determined up to 42 days by GPC, DSC, LSCM, spectrofluorimetry and SEM.

The delivery of substances to macrophages was investigated by co-culture of PLGA microspheres with DH82 cells *in vitro* up to 42 days. DH82 cells were seeded into the 6 well plates at 5×10^3 cells/cm². After one day, FD4 and FD10s loaded PLGA microspheres were added into the plates at a concentration of 1mg/ml.

RESULTS AND DISCUSSION

The different sizes PLGA microspheres loaded with FD4 and FD10s were prepared to study the degradation of the microspheres, the release rate of the model molecules and the phagocytosis of the microspheres. The results showed that the encapsulation efficiency was around 70%; the model molecules tended to aggregate and be distributed near the surface of

microspheres on the large microspheres ($\phi > 100\mu\text{m}$) but distributed more uniformly in the small microspheres ($\phi < 20\mu\text{m}$); from which there was controlled release, with 30 to 40% of the model molecules remaining in the microspheres after 6 weeks *in vitro* (Fig. 1). The morphology changes in the large microspheres were much greater than the smaller microspheres after 6 weeks. The small microspheres were effectively engulfed into DH82 cells, but most of the large ones were outside of the cells and easy to wash away after 1 week co-culture (Fig. 2).

Fig.1 Cumulative release of FD4 and FD10s from PLGA microspheres

Fig.2 PLGA microspheres co-cultured with DH82 cells after 1 week. Top: small microspheres ($\phi < 20\mu\text{m}$); bottom: large microspheres ($\phi > 100\mu\text{m}$)

CONCLUSION

The results indicate that the small PLGA microspheres ($\phi < 20\mu\text{m}$) are better candidates than big PLGA microspheres ($\phi > 100\mu\text{m}$) for the controlled-release of siRNA for targeting synovial macrophages.

INTRODUCTION

The extracellular matrix (ECM) of the peripheral nervous system (PNS) is comprised primarily of oriented collagen fibrils, arranged to delineate 2-20 μm diameter tube structures that act to guide neurites during regeneration¹. 3D environments have been proposed as more suitable to investigate and promote PNS repair, though these fail to replicate the structure of the native ECM. Electrospun scaffolds mimic the collagen fibril topography and are conducive to neurite growth, but fail to fully reproduce the tubular 3D organization². Hydrogels support neurites in a more 3D environment, but can also impede growth³. The objective of this work is to create a 3D culturing platform that is conducive to neurite growth and better captures the ordered heterogeneity of the PNS by emulating the scale, composition and structural organization of the ECM.

EXPERIMENTAL METHODS

Scaffold Fabrication. A hybrid hydrogel/fiber scaffold was realized by preparing a triple layered template of oriented fibers via electrospinning onto a gap electrode collector. Nanofibers comprised the upper and lower layers, prepared from a blended solution of 10% w/v 300PEOT55PBT45 and 4% w/v collagen in HFIP. Sacrificial microfibers prepared from a 50% w/v solution of PLA constituted the middle layer. The fiber template was heated to 65 °C for 1 hr to fuse the nanofibers to the periphery of the microfibers. Two sacrificial PCL plugs were fused to the fibers and placed approximately 7 mm apart. The template was embedded in a PEGDA precursor (+0.1% w/v Irigacure 2959) in a 15 mm diameter cylindrical mold. After crosslinking, the hybrid construct was placed in acetone at 50 °C to leach out the PCL plugs, forming 2 wells, and the PLA, forming channels to connect the wells.

Cell Culturing. Constructs were sterilized with EtOH and placed in 24 well plate. Dorsal root ganglions (DRGs) were extracted from Day 2 post-natal rat pups and placed in one well. Cultures were maintained for 8 days in Neural Basal medium with B27 supplement and 10 ng/ml NGF. Cells were fixed with 2% PFA, permeabilized with Triton-X, and stained for β 3-tubulin (neurite marker) and S100 (Schwann cell marker).

RESULTS AND DISCUSSION

The presence of interconnected microchannels between wells was verified by diffusion of fluorescent nanospheres between wells (Figure 1a). Channels were approximately 6.6 μm in diameter and SEM analysis revealed that the microchannels were lined with oriented nanofibers (Figure 1b). Seeded DRGs successfully innervated the hydrogel construct after 8 days (Figure 2), with a maximum length of 7 mm. Oriented microchannels with fibrous nanotopography lining the channel walls were successfully formed

within the compliant hydrogel matrix. These were shown to be of similar scale and structural organization to those observed in the PNS ECM. Constructs supported and guided neurite growth, validating the effectiveness of the 3D biomimetic platform.

Figure 1. (A) Interconnected microchannels formed within hydrogel between wells (Scalebar: 500 μm). (B) Hydrogel cross section at high magnification showing a microchannel with aligned nanofibers on the periphery.

This opens the possibility of investigating neurite growth in a more representative 3D environment. The flexibility of this construct allows for different hydrogels, microchannel sizes and nanofibers to be used, allowing for the controlled exploration of neurite growth. Furthermore, the fabrication can be scaled to create larger scaffolds suitable for implantation.

Figure 2. (A) Brightfield image of DRG outgrowth from well edge (double arrow) into hydrogel. (B) β 3-tubulin staining of neurite innervation of gel. (Scalebar 500 μm)

CONCLUSION

A 3D hybrid hydrogel/fiber construct was created with controlled, oriented anisotropic microchannel porosity and incorporated nanofiber topography to facilitate growth cone adhesion and guidance. Furthermore, this construct sustained directed growth of neurites.

INTRODUCTION

Adipose tissue engineering is a promising field for regeneration of soft tissue defects. However, only very thin implants or avascular tissue implants can be used in vivo for which vascularization is critical in thick implants¹. Another problem is finding a biocompatible scaffold with good mechanical properties. In this study, the aim is to develop an injectable hydrogel of decellularized adipose tissue and fibroin, entrapping both endothelial cells and adipose derived stem cells and characterize in vitro and in vivo. The approach is to develop a vascularized implant that will integrate with the host.

EXPERIMENTAL METHODS

Decellularization & Solubilization of Adipose Tissue

Adipose tissue was decellularized based on the study of Young et al. (2011)² with some modifications. Briefly, human lipoaspirate was washed in PBS, and decellularized in 1% SDS for 2h. Then, it is delipidized in isopropanol until tissue color was turned from yellow to white. After washed in dH₂O, sample was frozen at -80 °C, and then, it was freeze-dried.

Lyophilized matrix was completely dissolved in pepsin/HCl solution and the solution was neutralized by raising pH to 7.4 with 1M NaOH. 10x PBS was then added as it is diluted to 1x PBS. After solubilization, composition analyses were performed.

Gelation and Cell Encapsulation

Decellularized adipose tissue (DAT) solution was mixed with fibroin solution with different ratios. Then, all samples were gelled by vigorously vortexing.

For cell culture experiments, adipose derived stem cells (ASCs) were isolated from rat adipose tissue. Then, endothelial and adipogenic differentiation of ASCs were induced separately. Both predifferentiated cell types were embedded in DAT:Fibroin gel just after gelation was triggered by vortexing.

Implantation of Cell Encapsulated Matrix for In Vivo Tests

In vivo biocompatibility experiments were performed by subcutaneous implantation to test host response of to hydrogels devoid of cells. Before implantation, fibroin solution was sterilized with autoclave and DAT samples were sterilized with EtO. Cell embedded matrices will be wrapped around a host vessel, to determine whether a vascularized adipose tissue will be formed.

RESULTS AND DISCUSSION

Decellularization and Composition Analyses

Decellularization was confirmed by fluorometer measuring after Hoechst staining. Average DNA

amount was found as 90 ng/ml in solubilized DAT. By BCA assay, total protein amount in solution was found as 3 mg/ml. Thus, DNA amount can be accepted as 30 ng/mg of DAT matrix which is lower than that in many decellularization studies^{2,3}. Delipidization was observed by color change (Figure 1) and Oil Red O staining. Also, total collagen and sGAG assays showed that ECM components were remained after these treatments.

Figure 1. Adipose tissue a) After SDS treatment b) After alcohol treatment

Figure 2. DAT-Fibroin mixture a) Before vortexing, b) After vortexing.

Gelation and Cell Encapsulation

Mixing DAT samples with fibroin allowed rapid gel formation by vortexing (Figure 2). It also provided to adjust mechanical strength by changing fibroin to DAT ratio. Based on compression tests, the one which has the most similar mechanical properties to adipose tissue was selected for cell experiments.

In vivo implantation

Subcutaneous implantation of hydrogels (Figure 3) resulted with no immunogenic reaction or infection. This shows that decellularization and sterilization steps were performed successfully. Localized implantation in which hydrogels wrapped around the host vessel are under study. It is expected that endothelial cells inside the hydrogel will form a capillary network and they will bind to the host vessel passing through hydrogel.

Figure 3. Subcutaneous implantation of DAT – Fibroin mixture

CONCLUSION

DAT-fibroin hydrogel has many natural ECM components and results showed that injectable DAT:Fibroin hydrogels hold promise for adipose tissue engineering, important outcome for esthetical reconstructive surgery

INTRODUCTION

Calcium phosphate is bioactive, biodegradable graft material with excellent biological properties. However, its low strength limits its use to only non-stress application¹. We hypothesized that a composite of calcium phosphate cement reinforced with multiwall carbon nanotubes (MWCNTs) could enhance the strength of the material and widen its applications. In this paper we have discussed a simplified process of fabricating calcium phosphate cement by sol-gel technique² along with the uniform dispersion and incorporation of MWCNTs. As the material can potentially be replaced with new bone after a period of time, it will satisfy the key requirements of an ideal bone graft.

EXPERIMENTAL METHODS

Calcium phosphate was prepared by the addition of dibasic ammonium phosphate $(\text{NH}_4)_2\text{HPO}_4$ solution over calcium acetate $\text{Ca}(\text{CH}_3\text{COO})_2$. The volumes of the solution were calculated for a ratio Ca/P = 1.5. Non-stoichiometric hydroxyapatite precipitates were annealed at 1000-1200°C to obtain β -tricalcium phosphate. XRD analysis was performed to study the crystal nature of material.

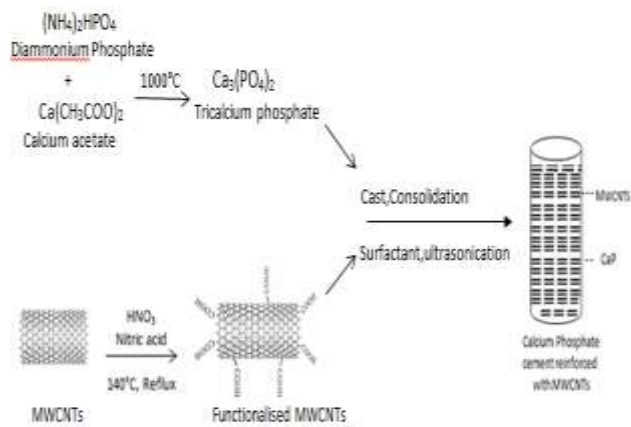

Fig 1. Simulative overview of process for reinforcement of CNTs in calcium phosphate matrix

Since as-received MWCNTs are hydrophobic they will be refluxed with 60% nitric acid to obtain carboxylated

MWCNTs (MWCNTs-COOH). Various surfactants were tried as dispersant to obtain uniform dispersion of MWCNTs in the solution containing calcium Phosphate particles. The final product will be cast and consolidated into cement blocks. The fundamental properties such as porosity, density and compressive strength of the final hardened body of the cement will be examined. The interaction of CNTs with the cement was examined using FT-IR, Raman spectroscopy and Scanning Electron Microscopy analysis. The implication of CNTs on the biocompatibility is being studied using osteoblast cell cultures.

RESULTS AND DISCUSSION

A uniform distribution of CNTs in calcium phosphate matrix (as depicted in the fig) was obtained. The functionalization and treatment of CNTs with surfactants increased their chemical compatibility with calcium phosphate. It is found that the efficacy of CNTs as reinforcement is dependent on the surface treatment, the plasticiser and the casting process. The addition of CNTs significantly improved the compressive strength of the cement. The implication of the CNTs on the biocompatibility is currently being studied using osteoblast cell cultures.

CONCLUSION

This paper presents an efficient method of synthesizing calcium phosphate cement reinforced with CNTs. The critical challenges in using CNTs are disaggregation and uniform dispersion. As the surface treatment of CNTs is vital to the biocompatibility of the resultant composites, an efficient method involving both mechanical method and chemical treatment to overcome this barrier is demonstrated. This would serve as a cost effective method of developing bone implant material.

Dynamics of filopodium-like protrusion and endothelial cellular motility on 1-D extracellular matrix fibrils

Niannan Xue¹, Cristina Bertulli¹, Amine Sadok², Yan Yan Shery Huang^{3*}

¹Department of Physics, University of Cambridge CB3 0HE, UK

³The Institute of Cancer Research, 237 Fulham Road, London SW3 6JB, UK

^{2*} Department of Engineering, University of Cambridge CB2 1PZ, UK yysh2@cam.ac.uk

The dynamic interaction between endothelial cells (EA.hy926) and single fibrils of gelatin was studied. Particular focus was paid to the cellular motility and the characteristics of cytoplasmic protrusions. The effect of ROCK inhibition on these two aspects were also investigated. The results are hoped to further our understanding in the role of ECM fibrils in guiding angiogenesis.

INTRODUCTION

Extracellular matrices (ECM) fibrils provide specific adhesive features, together with topographical and mechanical cues, conduct cellular behaviors. *In vivo*, individual cells would interface with one or more ECM fibrils organized in a three-dimensional fashion. Cytoplasmic slender projections such as filopodia were suggested to function as antennae to sense the biochemical and biophysical cues given by the surrounding substratum such as ECM, in turn guiding cellular motility. Since fibril structures are the building blocks of an ECM, studying endothelial protrusion interaction with a single ECM fibril can be seen as a simple and physiologically relevant model system.

EXPERIMENTAL METHODS

We employ near-field electrospinning^{1,2} to create ordered patterns of collagenous fibrils of gelatin, based on an acetic acid and ethyl acetate aqueous co-solvent system. ROCK inhibition of EA.hy926 was induced by H1152. Live cell imaging was performed using a Leica confocal microscope.

RESULTS AND DISCUSSION

The interaction between endothelial cells and extracellular matrix fibrils was recapitulated *in vitro*³. Live cell imaging shows that cellular migration along a gelatin fibril is accompanied by filopodial-like protrusion extension and retraction. When interfaced with a fibril, cells adopt a bipolar morphology with extended protrusions at both ends. Different modes of cell motility *vs.* temporal protrusion lengths are identified under normal culture and ROCK inhibition. Persistent migration was found to be one of the modes which permitted cell displacement for over 300µm at a speed of ~1µm/min. In particular, this migration speed is similar to fibroblast migration in a 3D collagen gel. However, it is to note that such a persistent migration is a rare event and majority of the time cells did not migrate further than their cell size.

Analyzing the patterns of protrusion length *vs.* cell displacement seems to indicate that short protrusions

better facilitate cell motility. ROCK inhibition, which significantly increased the temporal protrusion lengths, did not apparently alter the mean value of cell displacement; however, it had reduced the probability of long-ranged cell migration. Measuring the protrusion velocity indicates that the speeds of extension and retraction have very different distributions between the normal and the ROCK treated culture.

Occasional protrusion breakage is observed during cellular motility (see image below). Such protrusion breakage can occur on a variety of protrusion lengths (from 20µm to over a hundred microns). The associated characteristic lengths can act as indicators for cellular contractility

CONCLUSION

Near-field electrospinning of gelatin fibrils provides a simple and well-controlled model to recapitulate the ECM fibril topography. Future studies which involve comparison to *in vivo* systems are important to further validate the fibrils' physiological relevancy. Using this fibril system, we have defined the key morphological parameters of protrusion dynamics during cell motility. ROCK inhibition resulted in abnormally long protrusions, and diminished the persistent migration, but dramatically increased the speeds of protrusion extension and retraction. Finally, we also showed the breakage of protrusion during cell motility.

The Importance of Interconnectivity for Cell Invasion and Percolation through Collagen Scaffolds

J. Ashworth^{1*}, P. Buxton², T. Hart², S. Best¹ and R. Cameron¹

¹Cambridge Centre for Medical Materials, University of Cambridge, UK, *jca35@cam.ac.uk

²Geistlich Pharma AG, Wolhusen, Switzerland

INTRODUCTION

It is widely acknowledged that the efficacy of tissue engineering scaffolds is often limited by a lack of cell invasion into the porous structure. Such invasion is profoundly influenced by the pore size and interconnectivity of the scaffold. Whereas the effect of pore size is well-characterised in literature¹, interconnectivity is generally only studied qualitatively, with limited attempts at correlation with observed cell behaviour. Here a method based on percolation theory is implemented, to demonstrate that consideration of interconnectivity is vital for a thorough understanding of how cell invasion into tissue engineering scaffolds may be predictably controlled.

EXPERIMENTAL METHODS

Scaffolds were fabricated by freeze-drying a 1% w/v suspension of insoluble type I bovine collagen from Achilles tendon, hydrated in 0.05 M acetic acid. X-ray Micro-Computer Tomography (micro-CT) was used to produce a 3D representation of the scaffold structure. From this dataset, measurements of percolation diameter (d_c) were made. This parameter represents the diameter of a sphere able to pass through the pore space from one side of a scaffold to the other, and can be calculated using the expression²:

$$(d - d_c) \propto L^{-\frac{1}{\nu}}$$

Where d is the diameter of a sphere that can invade the pore space up to a distance L , and the constant ν is the standard value of 0.88 for percolation in 3D systems. Measurements of L and d were made using the software CTAn. The effect of pore size and percolation diameter on human primary fibroblast invasion was tested by surface seeding in triplicate, at 64,000 cells per 1 cm² scaffold. After 3 days of culture, Phalloidin-staining, cross-sectioning and confocal microscopy allowed measurement of mean invasion distances, displayed for each scaffold along with 95% confidence intervals.

RESULTS AND DISCUSSION

Independent variation of pore size and percolation diameter was found to be possible, as shown in figure 1.

Figure 1: SEM images of scaffolds with varying percolation diameter: (a) 60 μm, (b) 40 μm. Pore size (70 μm) and orientation constant. Colour indicates strut density, increasing from red-blue. Scale bar is 100 μm.

Increasing freezing temperature increased the pore size, as has been documented previously in literature³, but was also observed to change percolation diameter. However, varying the cooling rate was found to be an effective way of altering pore size, while keeping percolation diameter constant. Furthermore, as shown in figure 1, the substitution of (a) 0.05M acetic acid for (b) 0.001M hydrochloric acid in the initial collagen suspension changes percolation diameter independently. Using this knowledge, 4 scaffolds were created for cell invasion studies, to examine the effect of independent pore size and percolation diameter variation (figure 2).

Figure 2: Effect of pore size and percolation diameter on fibroblast invasion distance after 3 days of culture.

It was found that a larger percolation diameter corresponded to enhanced cell invasion ability. In fact, it could be seen that a change in percolation diameter can cause substantial differences in cell invasion, even when pore size is kept constant. Therefore a description of scaffold architecture in terms of pore size alone is an incomplete approach to characterisation.

CONCLUSION

Pore size and percolation diameter both influence cell invasion ability. Architectural characterisation of collagen scaffolds should therefore combine pore size measurements with quantitative interconnectivity analysis in order to present a complete picture of the structural factors that will determine cell response.

Novel Continuous Plastic Flow Synthesis of Phase Pure Nano-Sized Hydroxyapatite

Aneela Anwar, Jawwad A. Darr*

Clean Materials Technology Group, Department of Chemistry, University College London, 20 Gordon Street, London WC1H 0AJ, a.anwar.11@ucl.ac.uk

INTRODUCTION

Calcium phosphates (CaP) are the most ubiquitous family of bioceramics well known for their use as bone graft substitutes, coatings on metallic implants, reinforcements in biomedical composites and in bone and dental cements.¹ Hydroxyapatite (HA), $[\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2]$ is similar to biological apatite, the main mineral constituent of teeth and bone² because of its biocompatibility, bioactivity and low solubility in wet media. Such nano-bioceramics have been employed as a scaffold material to encourage new bone formation for osteoinductive coatings on metal implants and as a bulk bone filler.³⁻⁶

EXPERIMENTAL METHODS

Synthetic hydroxyapatite (HA) nanoparticles (~ 20 nm) were synthesised from aqueous solutions of calcium nitrate tetrahydrate and diammonium hydrogen phosphate mixed using a novel two pump continuous plastic flow synthesis (CPFS) system with a total reaction time of ca. 5 minutes performed under controlled temperature (60 °C) and pH 10. The product was obtained as a phase pure material with a stoichiometric Ca:P molar ratio of 1.67, without the need for a separate ageing step [Patent Filed UK Patent Application No. 1317747.2].

RESULTS AND DISCUSSION

The powders were then characterized by transmission electron microscopy (TEM), BET surface area analysis, X-ray powder diffraction, FTIR spectroscopy, Raman spectroscopy and X-ray photoelectron spectroscopy (XPS). Particles synthesized at 60 °C in 5 minutes residence time possessed remarkably high surface area of $264 \text{ m}^2 \text{ g}^{-1}$ and very small particle size of ~ 20 nm.

Figure 1. Transmission electron microscope images of hydroxyapatite nano-rods of sample HA60 synthesized by continuous plastic flow synthesis with scale bars, (a), (bar = 100 nm), (b), (bar = 20 nm),

Evaluation of *in-vitro* biocompatibility showed that HA disk-pressed powders supported osteoblast cell attachment and proliferation. The proposed synthesis strategy provides a facile and economical pathway to

rapidly obtain nano-sized hydroxyapatite with high purity, and ultra-high surface area.

Figure 2. MG63 morphology on HA discs. Cells were visualised at day 7 for cell nucleus (DAPI in blue) and cytoskeleton (phalloidin-FITC in green) for MG63s cultured on HA 60, and commercial HA. Scale bar is 100 µm.

CONCLUSION

The conclusions have to be based on the facts in evidence and should be limited to minimal speculation about the significance of the work.

“Males and females students were critical criteria used to determine their emotions during...Consequently; if emotions can incarcerate us by hiding our complexity, at least their expression can liberate us by displaying our authenticity.”

The effects of ascending and descending strain rate on the mechanical properties of canine cranial cruciate ligaments

Rosti Hama Rashid^{1*}, Brendan Geraghty¹, Ahmed Elsheikh¹ and Eithne Comerford²

¹School of Engineering, University of Liverpool, Liverpool, L69 3GH, UK, *R.Hamarashid@liv.ac.uk

²Institute of Ageing and Chronic disease and School of Veterinary Science, Faculty of Health and Life Sciences, University of Liverpool, Neston, CH64 7TE

INTRODUCTION

Mechanical properties of knee ligaments, such as the anterior cruciate ligament (ACL), are of clinical importance, as they are critical to provide the structural stability of a given joint. There were over two million knee ligament injuries reported in one study during the period of 2000 to 2005¹. In the United States, approximately 250,000 people experience ACL rupture annually, costing over 2 billion dollars per year¹⁻⁴. Similarly the cost of ligament rupture in comparative species such as dogs remain high; in 2003 management of cranial cruciate ligament (CCL) rupture estimated as costing over \$1 billion⁵. CCL rupture is the most common cause of hindlimb lameness in the dog⁶. The aim of this study is to determine the viscoelastic properties of CCLs, leading to study tissue engineered ligaments, novel ligament prostheses and role of proteins in their composition. In this study, viscoelastic behaviour of CCL was investigated by studying strain rate sensitivity. Strain rate sensitivity is a time-dependent characteristic in which stress-strain behaviour changes based on the rate at which the strain applied. Strain rate sensitivity is one of the four main forms of viscoelastic behaviour. Knowledge of strain rate sensitivity can aid mathematical modelling of ligament's response to mechanical forces and therefore help with the development of finite element analysis models. The biomaterial properties of the ligament could then be included in the numerical model to carry out parametric studies.

EXPERIMENTAL METHODS

Sample preparation

Six skeletally mature breed and age-matched dogs with no evidence of stifle (knee) osteoarthritis euthanased with full ethical permission were used. Entire stifle joints were frozen at -20 °C for at least 24 hours, defrosted at room temperature and the CCLs were dissected when required. The CCLs removed from the knee joint, leaving 10mm of bony parts at each sides of the ligament resulting in a femur-CCL-tibia complex, Figure 1(b).

Testing

Uniaxial testing was carried out on the canine CCL samples using an Instron 3366 testing machine (Instron, Norwood, MA) equipped with a 10N load cell (Instron, Part No. 2530-428). The samples were secured using a custom-built clamp, Figure 1 (a). Before mechanical testing, specimen length and cross-sectional area were measured^{7,8}.

A small preload of 0.1 N was applied, followed by preconditioning the sample to ensure samples are in their steady state condition. The ligaments were preconditioned by applying 10 cycles of loading-unloading^{9,10} to a maximum load of 10 N at a strain rate of 10%/min. Subsequently, the clamped Femur-CCL-Tibia sample subjected to cyclic tensile tests, with a maximum applied load of 10 N at three different strain rates of 0.1, 1 and 10 %/min. During the test, the ligament load-elongation curve was recorded by the Instron load cell and stored in a personal computer.

To study the effect of strain rate, ascending (0.1, 1 and 10%/min) and descending (10, 1 and 0.1%/min) strain rate tests were carried out. Each loading-unloading cycle, including the preconditioning procedure were followed by 6 min recovery period. Study on descending strain rate was necessary to confirm that the increase of stiffness is not due to extension of the tissue but it is due to the rate of the strain.

Figure 1: Custom designed clamps (a), and a clamped CCL complex mounted on the Instron testing machine.

Statistical analysis

The significance of associations between strain rate and mechanical stiffness (as measured by the tangent modulus), and the significance difference between ascending and descending regimes were assessed by ANOVA test. Analyses were performed in SPSS 20.0 (SPSS Inc., Illinois). $P < 0.01$ was considered an indication for statistical significance.

RESULTS AND DISCUSSION

In this study, two regimes (ascending and descending strain rate) were studied. The specimens exhibited non-linear stress-strain behaviour in both cases which can quantify the viscoelastic behaviour. The gradient of the stress-strain curve, the tangent modulus E , represents the stiffness of the ligament. Tangent modulus increased with increasing stress and strain rate, Figure 2. In agreement with previous studies¹⁷, it was also observed that the tissue showed statistically significant (p -value < 0.01) increase in stiffness when the strain rate increased. Statistical analysis ANOVA was carried out to see the difference between the two regimes and it was found that there is no significant difference between the two testing procedure with sig. value of $p = 0.109$ (p -value < 0.01).

Figure 2: Change in tangent modulus (E -tan) with stress for ascending and descending test regimes

CONCLUSION

As predicted, the ligament illustrated non-linear stress-strain behaviour, and stiffness increased with increasing strain rate level. Further investigation on testing for ascending and descending strain rate showed that the tissue behaviour doesn't depend on the strain rate order but on the level of the strain rate.

Bioactive glasses bond to and integrate with living bone in the body without forming fibrous tissue around them or promoting inflammation or toxicity. This discovering was carried out by Prof. Larry Hench, and provided a new concept of bioceramics that opened new perspectives in the field of bone grafting materials. Bioactive glasses, especially the Hench's bioglass 45S5, exhibit many of the properties associated to an ideal material for bone grafting and regeneration. The high biocompatibility and the positive biological effects of their reaction products (both leached or formed at the surface) after implantation [1], have made bioglasses one of the most interesting bioceramics during the last 40 years. In 1991, the incorporation of sol-gel chemistry to the preparation of bioceramics resulted into a new generation of bioactive glasses, which exhibited a very high potential to develop better implants with osteogenic capabilities [2,3].

Inspired by the work of Prof. Hench, our research group has made efforts to contribute to the knowledge in the field of bioactive glasses. The preparation of organic-inorganic hybrids materials have resulted in materials with better mechanical properties, while keeping the bioactive behaviour of bioglasses [4,5]. We have also developed a new generation of mesoporous bioactive glasses (MBGs). MBGs results from the incorporation of structure directing agents to the sol-gel synthesis of bioglasses [6]. This strategy results in highly ordered mesoporous materials with surface and porosity five times higher than those obtained for the conventional sol-gel bioglasses. MBGs exhibits the fastest in vitro bioactivity observed up to date. The real clinical significance is still unknown, as the ordered mesoporous structure allows incorporating osteogenic agents, osteoclasts inhibitors, antitumoral drugs, etc. thus providing an excellent potential for the treatment of cancer and degenerative diseases in bone tissue [7,8]. Moreover, mesoporous materials can be also

manufactured as 3D macroporous scaffolds and nanoparticles [9,10].

This lecture deals with the main contributions of our research team during the last decade, regarding new compositions -both inorganic and organic-inorganic hybrid materials- intended for bone tissue repairing. The proofs of concept for all these topics have been already assessed, and now we ought to carry out the transition from the bench to the bedside

Bioactive Glasses: from Hench to Hybrids

Julian R. Jones

Department of Materials, Imperial College London, UK julian.r.jones@imperial.ac.uk

INTRODUCTION

Larry Hench's Bioglass® has now been used in more than 1 million patients as a synthetic bone graft (e.g. NovaBone®, NovaBone Products LLC, FL) and is the active ingredient in Sensodyne Repair and Protect™ Toothpaste. Bioglass has outperformed other bioactive ceramics in comparative *in vivo* studies but its potential for bone regeneration is limited because it is only available as a particulate¹. A reason is that the original Bioglass 45S5 composition crystallises during sintering.

AMORPHOUS MELT-DERIVED SCAFFOLDS

New compositions now exist that can be sintered without crystallising and a new processing routes have been developed that can produce strong scaffolds, e.g. 3D printing and our foaming processes². *In vivo* studies of our foam scaffolds in an ovine model show 99% of the glass covered in new bone, including the internal pore structure. Laser spun glasses have potential in wound healing applications.

SOL-GEL SCAFFOLDS

Using the sol-gel foaming process also avoids the crystallisation issue and allows the use of more simple compositions, e.g. 70S30C; 70% SiO₂ and 30% CaO. *In vitro* data shows bone matrix production and active remodelling in osteoblast/osteoclast co-culture³. However *in vivo*, the results are more complex. The scaffolds only regenerated bone defects when preconditioned⁴ and then the bone ingrowth was similar to NovaBone and Si-HA (Actifuse®). Unlike the commercial products, pre-conditioned 70S30C scaffolds degraded and were replaced with new bone (Fig. 1).

Fig.1. Micro-CT of 70S30C foam in a rat tibia 3mm defect at 11wk

SOL-GEL HYBRIDS

All bioceramics scaffolds have the problem of being brittle. New developments in the synthesis of tough inorganic/ organic scaffolds with tailored degradation rates will be discussed. We have developed novel sol-gel hybrids with interpenetrating networks (IPNs) of degradable polymers and bioactive silica (Fig 2a). The aim is to create hybrid scaffolds with tailored degradation and mechanical properties that cells interact with as one material¹. However there are several challenges: The chemistry and processing is complex to create a successful bioactive hybrid. Challenges to overcome are: creating a porous structure while controlling degradation rate and mechanical properties. Critical to the success of the hybrids is achieving mechanical properties and controlled congruent degradation. This can only be achieved by synthesising hybrids that have covalent coupling between the IPNs.

HYBRIDS OF NATURAL POLYMERS

Natural polypeptides such as gelatin⁵ and poly-gamma-glutamic acid^{6,8} have been used. They are biodegradable and contain functional groups such as -COOH, which can be functionalised with a coupling agent for linking to the silica. Polysaccharides such as chitosan have also been used, but the presence of the -NH₂ group instead of -COOH changes the mechanism of coupling⁹.

Fig. 2 (a) schematic of IPNs; micro-CT images of hybrid scaffolds made by (a) foam, (b) 3-D printing

HYBRIDS OF SYNTHETIC POLYMERS

Synthetic polymers can be synthesised with the coupling agents built in, e.g. acrylate based polymers containing links of TMSPMA, spacer monomers and biodegradable linkers. Degree of branching has a large effect on mechanical properties.

Conventional polymers such as polycaprolactone can also be functionalised to enable bonding via coupling molecules such as GPTMS.

SCAFFOLD PROCESSING ROUTES

Processing routes of sol-gel foaming (Fig. 2b), 3D printing (Fig. 2c), freeze casting and electrospinning will be compared.

CONCLUSION

Bioactive glass scaffolds can be produced by sol-gel processing and using new compositions of melt-derived glasses. Pore structure and ion release have to be controlled to ensure a good response *in vivo*. Hybrids have the potential to combine bioactivity with controlled degradation and mechanical properties.

Clinical Use of S53P4 Bioactive Glass in Neurosurgery – Case Reports of Tumor Surgery, Infected Cervical Spine and Mucopyelocoe of the Frontal Sinuses

Janek Frantzen¹

¹Department of Neurosurgery, Turku University Hospital, Finland, janek.frantzen@tyks.fi

INTRODUCTION

Bioactive glasses (BAGs) are a group of synthetic surface-active composition-dependent silica-based biomaterials with osteoconductive, osteopromotive, and even angiogenic as well as antibacterial properties. The bone bonding properties of the two original BAGs (Bioglass® 45S5 and S53P4) were first delineated by Larry Hench in the early 1970's¹. BAG S53P4 has antibacterial properties, which have been suggested to be caused by the initial high pH and the subsequent osmotic effect caused by the dissolution of ions from the glass. Furthermore, BAG S53P4 has been shown in vitro to have effective bacterial-growth-inhibiting properties towards 17 anaerobic bacteria and 29 clinically important aerobic bacteria^{2,3}. BAG S53P4 has been successfully used as a bone substitute in the treatment of osteomyelitis of the spine and lower extremities⁴.

In general, it can be stated that in cases of infection in a surgical field all bone graft substitutes will be affected as if they were foreign objects, except for BAG, which has antibacterial properties and can potentially withstand bacteria to some extent.

METHODS

The following three clinical cases were operated by the author at the Turku University Hospital, Turku, Finland. Two of the patients were suffering from difficult to treat infections. The first patient got an iatrogenic cervical spondylodiscitis due to an perforation of the hypopharynx during revision surgery for malunion of level C3-C4. The second patient was treated for a mucopyelocoe in the left frontal region extending from a pansinusitis to the frontal bone and frontal lobe of the brain. Both were treated with a thorough debridement, broadspectrum antibiotic and the infection site was filled with S53P4 bioactive glass granules (Bonalive® Biomaterials Ltd, Turku, Finland). The third case was a patient with benign bone tumor of the skull where the surgical bone defect was filled with a recently developed bioactive glass putty (S53P4 granules with a water-soluble synthetic binder, Bonealive® putty, Bonalive Biomaterials Ltd, Turku, Finland).

RESULTS AND DISCUSSION

The patients have recovered initially well and the implanted material was well tolerated. No further reoperations were needed. For the infection cases, the follow-up is 3 months for the cervical spondylodiscitis and 10 months for the mucopyelocoe patient. Antibiotic treatment has ended and no recurrence of infection was observed. Thorough postoperative workup including plain X-rays, computed tomography (CT) and magnetic resonance imaging (MRI) has been performed in addition to the clinical follow up. For the tumor patient a 10-month follow up will be completed (5-months as writing). The healing of the wounds and no recurrence of the tumor has been noted on postoperative CT and MRI images.

The pre-clinical results in the literature concerning BAG's osteoconductive and osteopromotive properties are well translated into the clinical work in the field of surgery^{5,6}. These clinical infection cases describe a traditionally difficult to treat entity with a common need for concomitant revision surgery. The newly developed BAG putty has proven to be easy to use and has performed well in the filling of bone defects in the field of neurosurgery,

CONCLUSION

BAG S53P4 seems to be a well tolerated bone graft expander and bone void filler with broad anaerobic and aerobic antibacterial properties and as seen in these two difficult infection cases has performed well.

Bioactive glass S53P4 in the treatment of osteomyelitis – multicenter study

Nina Lindfors¹, Carlo Romano²

1. Helsinki University Central Hospital, Finland, nina.c.lindfors@hus.fi

2. Galeazzi Institute, Milano, Italy

INTRODUCTION

Bioactive glass (BAG) S53P4 is an osteostimulative bone substitute with proven antibacterial and bone bonding properties. In 2011 BAG-S53P4 received official indication for treatment of osteomyelitis.

This study shows that BAG-S53P4 can be used in treatment of osteomyelitis with excellent results. The best indication seems to be infected cavitory defects with or without fistular formation.

PATIENTS AND METHODS

In a retrospective multicenter study 67 patients (49 males, 18 females) with verified osteomyelitis were treated with BAG-S53P4 as a bone substitute. Several of the patients had previously undergone a number of procedures without success. The mean age of the patients was 50 years (16-87). According to the Cierny classification, most patients were of type 3. The location of the osteomyelitis was mainly in the tibia (N=33) followed by the femur (N=13) and calcaneus (N=7). In three patients the osteomyelitis was localized in the spine. The most common pathogens causing the osteomyelitis were *Staphylococcus aureus* or MRSA, followed by *Pseudomonas aeruginosa*. In 59 patients the procedure was performed as a one-stage procedure.

RESULTS

The mean follow-up was 27 months (3 months – 6 years and 8 months). Fifty-one patients had a total follow-up of more than one year. The total success rate was 90%. Six complications occurred in 6 months and they were either related to technical surgical problems or to lack of co-operation. Seroma leakage was observed only in one patient. In one patient an infection recurrence, related to incomplete debridement, occurred after a four-year follow-up.

CONCLUSION

In Vivo and In Situ Bioprinting of Cells and Biomaterials to Guide Tissue Repair

INTRODUCTION

The development of Computer-Assisted Medical Interventions (CAMI) results from converging evolutions in medicine, physics, materials, electronics, informatics and robotics. CAMI aim at providing tools that allow the clinician to use multi-modal data in a rational and quantitative way in order to plan, simulate and execute mini-invasive medical interventions accurately and safely. In parallel, technological advances in the fields of automation, miniaturization and computer aided design and machining have also led to the development of bioprinting technologies which could be defined as the computer-aided, layer-by-layer deposition, transfer and patterning of biologically relevant materials.

EXPERIMENTAL METHODS

In this paper, we present the first demonstration of bioprinting 3D tissue constructs in situ and in vivo. These constructs were realized by depositing sequentially a collagen solution (type I) and mouse mesenchymal stem cells (from D1 cell line) that were realized using Laser- Assisted Bioprinting into critical size mouse calvaria defects. The MSC patterns were initially observed using intravital microscopy and D1 cells previously infected with lentivirus expressing the red fluorescent protein tdTomato. Cell proliferation was also followed-up till 8 weeks by measuring bioluminescence from D1 cells previously infected with a luciferase-expressing lentivirus using photon-imager (Biospace). Histological analysis of printed tissues was done at different time points using decalcified sections and X-ray microtomography.

RESULTS AND DISCUSSION

Laser-assisted Bioprinting allows to deposit patterns of cells in situ and in vivo (Fig.1) at a cell-level resolution. D1 cells printed in vivo survive, migrate and the results show a proliferation in vivo for 35 days. Moreover, histological analyses of the decalcified samples observed after 5 weeks of healing revealed presence of newly formed trabecular or woven bone (Fig.2).

Fig.2. Histological pictures (HES staining) of materials implanted in the calvaria defects after 5 weeks. (a) Frontal section of the calvaria implanted with collagen and D1td- Tomato cells (disk) (x2). (b) High magnification of site implanted with collagen and D1Td-tomato cells (ring) (X10).

CONCLUSION

In conclusion, these results pave the way of using bioprinting technologies for Computer-Assisted Medical Interventions. More precisely, we show that 3D tissue constructs can be printed in vivo and in situ in relation with defect morphology. Interestingly, we demonstrate that printing cells in situ with a cell-level resolution tends to orientate tissue repair.

In Vivo Evaluation Of Bone Integration Of Poly(Vinyl-Alcohol) Hydrogel Fibers For Ligament Reconstruction

D. Moreau¹, A. Villain^{1,2}, M. Bachy², D.N. Ku³, D. Hannouche², H. Petite² and L. Corté¹

¹Centre des Matériaux Pierre-Marie Fourt, Mines Paristech, France. david.moreau@mines-paristech.fr

²Laboratoire de Bioingénierie et Bioimagerie Ostéo-Articulaire, Université Paris Diderot, France.

³George W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, USA.

INTRODUCTION

The design of an artificial device that successfully and durably replace torn ligaments is a long-standing challenge and demand in orthopedics. It could alleviate drawbacks and issues associated with autograft reconstruction, including donor site morbidity, graft availability and long recovery¹. Recently a new artificial system made of poly(vinyl alcohol) (PVA) hydrogel fibers has been shown to reproduce closely the tensile behavior of native ligaments². The potential of these systems as ligament substitutes is supported by the biocompatibility of PVA hydrogels, which has been found to be highly satisfactory in multiple applications³. Nevertheless, the *in vivo* response to these hydrogel fibers as ligament substitutes has not been explored hitherto. Here, we report the first *in vivo* evaluation of these implants in a rabbit model of tibial bone tunnel⁴. With this work, we explore whether these systems can be processed in agreement with sterile fabrication and implantation procedures.

EXPERIMENTAL METHODS

Implant fabrication

Implants were composed of cords of 15 twisted threads of 15 twisted PVA monofilaments, as presented in ref. 2. Gluing between fibers was produced by dip-coating in a 10wt% PVA aqueous solution and cross-linking of the PVA solution by applying three freeze-thaw cycles. Prior to surgery, implants were stored in physiological serum and sterilized by gamma irradiation.

Implantation protocol and follow-up

Six NZ white rabbits were implanted following a revised animal model by Li *et al.*⁴ (Fig 1a). PVA hydrogel implants were inserted in an extra-articular tibial bone tunnel of 2 mm of diameter and approximately 1 cm long. After implantation, animals were let free of any movement and fed *ad libitum*. Micro-CT scanners were performed at Day-0, 4 and 6 weeks. Histological study has been performed at 6 weeks. Samples surface was stained with Stevenel blue and Van Gieson picrofuchsin. The *in vivo* study was approved by the national ethical committee under the reference N09 (CEEALV/2011-02-01).

RESULTS AND DISCUSSION

Surgery was performed with no major difficulties. Implants were inserted into the bone tunnel without forcing and sutured to the periostum. Animals healed normally with no signs of inflammation nor weight loss. Micro-CT observations showed no bone osteolysis, as illustrated in Figure 1b at four weeks post-implantation. In several cases (N=4), new bone formation was noticed

growing from the internal surface of the cortical bone towards the middle axis of tibia (white arrows).

Figure 1: a) Implantation site (dashed lines); b) Micro-CT observation showing implant through the tibial tunnel at 6 weeks. c) Histological observation: (I) implant, (B) bone tissue, PVA fiber (black arrow), fibrous tissue layer (white arrow).

Histological analysis shows that the fiber assemblies remained intact after six weeks, as shown in Figure 1c. Fibers hold together and no fiber nor coating fragments were found in the surrounding tissues. A fibrous tissue layer was formed around the implant with a variable thickness and some direct contacts between bone and fibers. Remote bone formation around the implant was also noticed confirming the micro-CT observations.

CONCLUSION

This study reports the *in vivo* characterization of PVA hydrogel fibers in bone tunnels. Implants have been well tolerated. The biocompatibility observed for these systems in this animal model validates a manufacturing and bone implantation process that could serve as a basis for full ligament reconstruction in animal models.

Understanding nuclear deformation capacity of cancer cells thanks to micropillared surfaces

Florent Badique¹, Melanie Eichhorn², Jürgen Rühle², Oswald Prucker², Jean-Noël Freund³ and Karine Anselme^{1*}

^{1*} Mulhouse Materials Science Institute (IS2M), CNRS UMR7361, Université de Haute-Alsace, France,
karine.anselme@uha.fr

² Laboratory for Chemistry and Physics of Interfaces, IMTEK, University of Freiburg, Germany

³ INSERM U1113, University of Strasbourg, France

INTRODUCTION

Control of the cell behaviour onto artificial surfaces determines their usefulness in medical applications, such as medical implants or diagnosis tools. We have shown that a strong deformation of the nucleus occurs when cancer cells are brought into contact with polymer micropillars with a square morphology on top¹. On the contrary, healthy cells only deform during the initial stages of adhesion and immortalized cells show an intermediate deformation between the healthy and cancerous cells². These strong deformations of cells and of their organelles which don't affect viability and proliferation draw an analogy with the cell deformation occurring during metastatic process. These last years, we explored the role of materials properties as well as the biological mechanisms involved in this nuclear deformation in order to elucidate the mechanobiology of cancer cells on biomaterials³. Here, we propose to summarize the last results obtained in our group.

EXPERIMENTAL METHODS

Several cancer cells from different tumour origins (osteosarcoma, colon carcinoma) were cultured on polymer micropillared substrates. Cell adhesive [poly(l-lactic acid) PLLA, poly(n-butyl acrylate) PnBA] and cell repellent polymers [poly(dimethylacrylamide) PDMAA] were used in order to elucidate the role of surface chemistry in the adhesion and deformation of cells. Topography influence was explored by changing size, height and spacing between square micropillars but also pillar morphology (triangle, rectangle, rhombus...). Inhibitors of cytoskeleton and LINC complex molecules (cytochalasine D, nocodazole, blebbistatin, siRNA against lamin, nesprin 2, Sun1...) were used to determine the essential actors of nuclear deformation. Finally, movies of living cells deforming between pillars were acquired thank to an upright confocal microscope equipped with a cell culture chamber.

RESULTS AND DISCUSSION

Both osteosarcoma and carcinoma cells deform on micropillars. Osteosarcoma cells deform fast during adhesion (<6h) while carcinoma cells form cell-cell connections before to deform as a cell layer (~48h). The use of cytoskeleton inhibitors demonstrates that actin and intermediate filaments are the main actors of the deformation. Surprisingly, myosin is not essential to complete deformation. Some proteins of LINC complex (sun1 and nesprin2) are also needed. Changing shape of pillars does not modify the deformation of cells while increasing pillar height improves it. The capacity of cells to deform their nucleus when spacing between

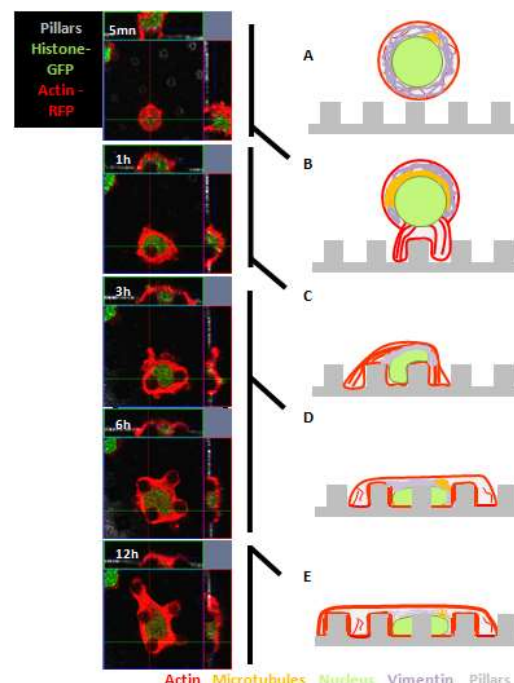

Fig. 1: Images of an osteosarcoma cell (SaOs-2) deforming on square pillars (size 7x7µm, height 6µm and spacing 7µm).

pillars is reduced is function of cell lines. When tops of pillars are cell repellent and walls of pillars cell adhesive, nuclear deformation increases. When the inverse is done, cells are also able to deform but less. Movies of living cells allowed us to elucidate the mechanism of deformation (Fig. 1). First, osteosarcoma cells adhere on pillars by focal adhesions. Secondly, an actin cap forms above the nucleus to push down and deform it between pillars. Further, the cell body spread over several pillars using actin and vimentin fibers to maintain the nucleus deformed during migration.

CONCLUSION

Micropillared substrates are useful tools for mechanobiology studies of cancer cells. Moreover, they are potential diagnosis tool to determine the cancerous potential of cells.

Fatigue behaviour of selective-laser-melted nickel-titanium scaffolds

Therese Bormann^{1,2}, Bert Müller², Waldemar Hoffmann^{1,3}, David Wendt³ and Michael de Wild^{1*}

^{1*}Institute of Medical and Analytical Technologies, University of Applied Sciences Northwestern Switzerland, Muttenz, Switzerland, michael.dewild@fhnw.ch

²Biomaterials Science Center, University of Basel, Basel, Switzerland

³Department of Biomedicine, University Hospital Basel, Basel, Switzerland

INTRODUCTION

The shape memory alloy nickel-titanium is a promising biomaterial for scaffolds and load-bearing implants. It exhibits pseudo-elastic or pseudo-plastic behaviour that allows mechanically stimulating the adherent cells and the adjacent tissue and, thus, can improve the osseointegration.¹ Its damping capacity allows for shock absorption.² For a metal, NiTi has a low elastic modulus, which facilitates the implant design to avoid stress-shielding.²

Selective laser melting (SLM) enabled us to fabricate NiTi scaffolds.^{1,3} Such SLM-scaffolds, however, are porous and reveal an irregularly shaped surface owing to partially integrated powder particles. These defects have a significant impact on the mechanical properties of the scaffolds and related future load-bearing implants. A detailed analysis of the fatigue behaviour is, therefore, highly desirable and the focus of this study.

EXPERIMENTAL METHODS

Fig. 1 represents a NiTi scaffold 4 mm high and 8 mm in diameter that we built by means of the SLM-Realizer 100 (SLM-Solutions, Lübeck, Germany) using NiTi powder (Memry GmbH, Weil am Rhein, Germany) with particle sizes between 35 and 75 µm. The scaffolds were designed to match the geometry of our compression bioreactor (CBR). The universal testing machine Zwick-Roell Z100, Ulm, Germany served for static compression loading with a speed of 0.5 mm/s. Uniaxial dynamic compression along the scaffold's cylinder axis was carried out by means of a servo-hydraulic testing machine (walter+bai AG, Löhningen, Switzerland) with a sinusoidal loading profile between 40 and 150 MPa mean stresses and a frequency of 10 Hz.

Ø 8 mm,
strut thickness ~300 µm

Fig. 1: The three-dimensional rendering of the SLM-NiTi scaffold shows the irregular surface topography.

RESULTS AND DISCUSSION

Static compression testing showed the pseudo-elastic response of the SLM-scaffolds, since they recovered up to 7 % of the applied deflection. The overall elastic modulus of the scaffolds was about (1.3 ± 0.3) GPa. The compressive strength referred to about 200 MPa. Cracks, however, were initiated already at deflections exceeding 5 % of the scaffold height, in particular at the hinge positions. From dynamic compression testing, a

stress-cycle diagram was derived by counting the number of load cycles until fracture at given loading amplitude, see fig. 2. The endurance limit of the NiTi scaffolds for reaching $5 \cdot 10^5$ cycles was about 50 MPa. Since the lattice-based scaffold geometry comprise of an inhomogeneous cross-section,⁴ the calculated stress is based on the minimal cross-sectional area of 7.9 mm². The fatigue performance suits the requirements of the CBR. Further, the formation of a well-defined Woehler-curve demonstrates that the SLM scaffolds exhibit reproducible fatigue behaviour even though the presence of small internal pores and a rough scaffold surface topography.

Fig. 2: The Woehler-diagram of the SLM-scaffolds. Run-outs achieving $5 \cdot 10^5$ loading cycles are marked with arrows.

CONCLUSION

The investigated static and dynamic mechanical properties confirm the performance of SLM NiTi scaffolds for load-bearing implants. Since the SLM fabrication process allows dedicated adjustment of the geometry, the mechanical properties such as the elastic modulus can be optimized to match the biomechanical characteristics of the implantation site.

3D Printed Silica- Gelatin Hybrid Tissue Scaffolds

Maria Nelson¹, Siwei Li¹, Oliver Mahony¹, Molly M. Stevens¹, Gowsihan Poologasundarampillai¹, Kamel Madi², Peter D. Lee², Julian R. Jones¹

¹Department of Materials, Imperial College London, UK

^{2*} School of Materials, The University of Manchester, Oxford Rd, Manchester UK m.nelson12@imperial.ac.uk

INTRODUCTION

Tissue scaffolds provide a bioactive surface and porous structure to act as a temporary template to guide tissue repair. Using a 3D printing technique, the micro and macro structures can be tailored to different tissues and defect shapes. Sol-gel hybrids have nanoscale interpenetrating networks of inorganic and organic components. Use of a hybrid material allows tailoring of scaffolds as the composition can be adjusted during synthesis to alter degradation rate and mechanical properties¹. The aim was to directly print 3D structures from a gelatin– silica hybrid sol using (3-glycidioxypropyl) methyldiethoxysilane (GPTMS) as a coupling agent. Currently the work is focussed on bone and cartilage tissue regeneration.

EXPERIMENTAL METHODS

Gelatin was functionalized with GPTMS in dilute HCl and mixed with hydrolysed TEOS to create a sol. The sol was moved to a 40°C oven for 6 hours until the printing viscosity was achieved. The 3D printer was programmed to print the sol into 1cm cubes with 90° mesh structures. The scaffolds were sealed in a container and aged for 6 days followed by freezing at -20°C and freeze drying under vacuum at -111°C.

Hybrid scaffolds were characterized by FTIR, compression testing and imaging using SEM and X-ray microtomography. A study into the rheological characteristics of the gels at the point of printing was also carried out. The cytotoxic activity of the dissolution products were evaluated and cellular attachment of osteoblast and chondrocytes were analysed by immunohistochemical staining.

RESULTS AND DISCUSSION

To create a 3D structure the material must gel at the point of printing. Gelation is controlled by condensation of the silica-gelatin network. An as printed scaffold is shown in Fig. 1a. When designing a print file, the variables to consider are the spacing between individual struts, the height of each strut, the speed of printer head travel, printing nozzle diameter and rate of material deposition. Different scales and structures can be achieved during printing and retained by freeze drying (Fig. 1b and 1c).

Figure 1. (a) 3D printing a scaffold; (b) and (c) SEM images of freeze dried scaffolds with a strut separation of 1mm and 0.5mm respectively.

X-ray imaging shows the structure of the scaffold to be porous in the x and z axis and dense across the XZ planes which imparts increased compressive strength; 1MPa +/- 0.2MPa parallel and 0.7MPa +/- 0.1MPa perpendicular to the dense planes. The scaffolds tested had strut separation of ~500µm, strut width of ~70 µm.

Figure 2. 3D reconstruction of a Silica-Gelatin scaffold (Diamond Light Source). (a) YZ view, (b) XY view, (c) XZ view

The metabolic activity assay demonstrated the material to have minimal cytotoxic activity and 3-D scaffolds were capable of facilitating cell attachment and spreading following a 3-day culture period (Fig. 3).

Figure 3. Confocal fluorescence images of (a) MC3T3 and (b) ATDC5 cells on the 3D printed scaffolds stained for cytoskeletal proteins actin (red), vimentin (green) and nuclei (blue).

CONCLUSION

3D printing silica– gelatin hybrids with covalent coupling directly from sol has been achieved and a variety of structures printed. This is a biomaterial suitable for bone regeneration and has potential for use in cartilage with a tailorable structure and composition. By imaging the structure, further developments to the design can be made.

Tailoring Crimp Patterns of Electrospun Fibers by Using Thermal Shrinkage

H. Chen^{1,2*}, D. Baptista¹, J. Crispim¹, D. Saris¹, H. Fernandes¹, C.A. van Blitterswijk^{1,2}, R. Truckenmuller^{1,2}, L. Moroni^{1,2}

²Department of Complex Tissue Regeneration, Maastricht University, The Netherlands

INTRODUCTION

The periodic waviness of native collagen fibrils is observed in nearly all human tissue, such as tendon, blood vessels and valve leaflets¹. The features of crimp structures ensure that loads are sustained both by the surrounding extracellular matrix (ECM) and by the fiber network at low levels of tensile strain². A set of techniques has been developed to fabricate fibers with crimped, wrinkled and wavy structures for tissue engineering^{2,3}. For example, polyurethane buttressed rectangular membranes can be pre-extended and clamped over collagen fibers. The membranes are then relaxed to generate microcrimps, which are frozen at -80 °C and fixed in glutaraldehyde vapors. These microcrimped membranes can be used as templates to create ECM mimicking meshes although the fabrication procedures are multistep and complicated. Denver *et al.* found the aligned fibers from electrospinning (ESP) undergo crimping after removal from a mandrel used as a collector³. However, only limited control over the generated crimp patterns could be achieved. Here, we present a simple and versatile method to produce crimp-patterned electrospun fibers by using thermal shrinkage.

EXPERIMENTAL METHODS

A 20% (w/v) solution of Polyactive® (PA) (PolyVation, The Netherlands) was prepared in a 80/20 v/v mixture of chloroform and 1,1,1,3,3,3-hexafluoro-2-propanol, and stirred overnight at room temperature before ESP. The flow of the polymer solution was controlled by a pump at a feeding rate of 5 ml/h. The distance between the needle tip and the collector was set to 15 cm and the applied voltage was 16 kV. Fibers were deposited on a poly(lactic acid) (PLA) monoaxially oriented film. The thickness of the fiber meshes was controlled by the deposition time. Fiber-film constructs were then transferred to an oven pre-heated to 75 °C for 1 min to allow shrinkage of the PLA film and the formation of crimp patterns on the fibers. The morphology of the fibers was analyzed by scanning electron microscopy. Human mesenchymal stromal cells (hMSCs) were cultured on the wavy fibers to instigate the improvement of cell infiltration into the scaffold. Given the resemblance of the obtained fibers with the crimp patterns typical of tendons and ligaments we investigated if the wavy patterns could regulate a key signaling pathway involved in tendon and ligament maintenance TGF- β pathway. A TGF- β reporter cell line (T-MLEC) was seeded on flat and wavy fibers and the activation of the reporter was analyzed after 5 days of culture.

RESULTS AND DISCUSSION

Electrospun fibers were successfully fabricated with crimped structures. Crimp wavelengths varied between

0.7 to 10 μ m, depending on the processing conditions during ESP and the orientation of the electrospun fibers. The crimp pattern was dependent on the thickness of the fiber layer. For fiber layers with a thickness less than around 0.28 ± 0.10 mm, crimping occurred only on single fibers. Above this thickness threshold, crimping transferred to the whole electrospun sheet (**Figure 1**). The crimp pattern could be controlled by changing the orientation of depositing fibers. After 5 days of culture, an improvement on cell infiltration into the crimp scaffold was observed when compared to the flat scaffold alone. In addition, the crimp scaffold led to 1.7 times higher activation of the TGF- β reporter cell line when compared to the flat scaffold

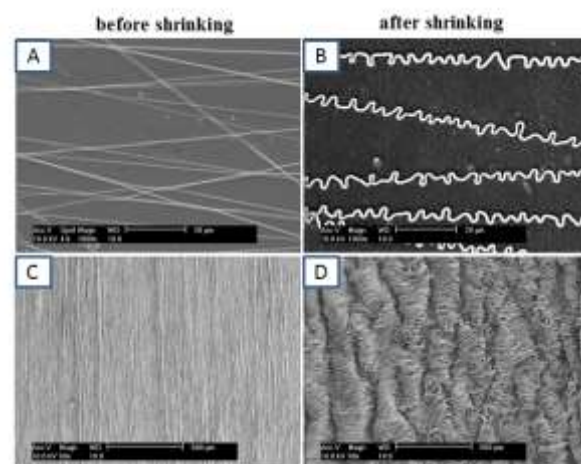

Figure 1. PA fibers before and after shrinking, showing crimp patterns at single fiber (A, B) and multiple fiber (C, D) levels.

CONCLUSION

PA fibers with crimp patterns were successfully fabricated in a very simple manner by controlled thermal shrinkage. The degree of crimp (amplitude and wavelength) was adjusted by the shrinkage extent of PLA films and the control of crimped patterns can be tailored by the thickness of the electrospun meshes. Furthermore, crimped structures improved hMSCs penetration into scaffolds and showed potential to be used in tendon and ligament engineering.

E-mail: carla.silva@dep.uminho.pt

INTRODUCTION

Chondroitin sulfate (CS) consists of repeating glucuronic acid (GlcA)/N-acetyl-galactosamine (GalNAc) disaccharide units joined by β 1,4 and 1,3 linkages respectively.¹ Multiple sulfotransferases involved in 4-O and 6-O sulfation of GalNAc units are responsible for the obtaining of CS with different degree of sulfation (0.1 – 1.3 per disaccharide unit) and patterns; CS may contain sulfate groups in both 4- and 6-positions the GalNAc unit (CS-E) but may also be exclusively 4-sulfated (CS-A) or 6-sulfated (CS-C).^{1,2} These different sulfation patterns influence the interactions between CS and proteins in the extracellular matrix or/and in the basement membrane and thus, can be critical in important physiological processes.² Herein, we demonstrate how the activity of two important enzymes, namely hyaluronidase and chondroitinase, are affected by the sulfation pattern of CS. We have established a protocol including GPC for the real time determination of the mechanism of enzyme action and ultrafiltration to obtain well defined oligosaccharides.

EXPERIMENTAL METHODS

The enzymatic digestion of CS-A, CS-C and CS-E by hyaluronidase and chondroitinase ABC was performed using 0.02Uenzyme/mg in phosphate buffer (0.1M, pH= 7.4) at 37°C for 48h. Aliquots of the reaction were taken at 1, 4, 8, 24 and 48 h. The enzyme was deactivated by heating and removed by centrifugation. The digested samples were then fractionated by ultrafiltration using 10kDa and 1kDa cut off membranes. All the products were lyophilized and analysed by gel permeation chromatography (GPC) and nuclear magnetic resonance (NMR).

RESULTS AND DISCUSSION

Digestion with Hyaluronidase

Hyaluronidase showed enhanced activity toward a 6-sulfation-rich substrate (CS-C, Table 1). In addition, the substantial distributions toward medium sized-polysaccharides support an endolytic mechanism of action (Fig. 1).

Table 1: Molecular weight and Infra-red (IR) area of digested species of CS by hyaluronidase for 24h

	CS-A (84kDa)	CS-C (54kDa)	CS-E(146kDa)
1h	42kDa (71.0%)	37kDa (73.6%)	72.6kDa (82.0%)
	1.2kDa (0.6%)	-	1.75kDa (1.1%)
	914Da (23.9%)	774Da (21.3%)	914Da (15.5%)
	558Da (4.6%)	495Da (5.0%)	690Da (1.0%)
24h	24.1kDa (72.4%)	11.4kDa (77.3%)	54.6kDa (76.4%)
	1.9kDa (1.6%)	-	1.9kDa (2.7%)
	940Da (22.0%)	369Da (17.7%)	936Da (18%)
	581Da (3.9%)	254Da (5.1%)	573Da (2.9%)

Figure 1: Schematic presentation of hyaluronidase endolytic action (red line) toward CS-C.

Digestion with Chondroitinase ABC

Similarly to the hyaluronidase, the CS-C was digested at higher degree (higher amount of low molecular weight species) as compared with CS-A and CS-E (Table 2). However, in this case low molecular weight species (disaccharides) were the major products of digestion, suggesting exolytic cleavage activity for chondroitinase (Fig. 2).

Table 2: Molecular weight and Infra-red (IR) area of digested species of CS by chondroitinase for 24h

	CS-A (84kDa)	CS-C (54kDa)	CS-E (146kDa)
1h	88kDa (83.0%)	-	130kDa (84.0%)
	1.8kDa (1.2%)	4.3kDa (14.4%)	2.2kDa (3.0%)
	948Da (13.1%)	1.7kDa (68.4%)	1.7kDa (68.4%)
	558Da (2.3%)	861Da (17.2%)	633Da (1.6%)
24h	78.7kDa (80.8%)	-	118kDa(82.0%)
	4.7kDa (1.3%)	5.5kDa (6.9%)	2.1kDa (3.9%)
	1.71kDa (1.0%)	1.9kDa (75.3%)	991Da (12.2%)
	934Da (14.3%)	990Da (17.7%)	-
	574Da (2.6%)	-	585Da (1.8%)

Figure 2: Schematic presentation of chondroitinase exolytic action (red line) toward CS-C.

CONCLUSION

The catalytic profiles of the studied enzymes were determined: hyaluronidase is mainly endolytic whereas chondroitinase acts via both endolytic and exolytic mechanisms. Both enzymes showed preference for CS-C, however in a different extent. Medium sized polysaccharides are obtained with hyaluronidase whereas higher amount of low molecular species are obtained with chondroitinase. This protocol can be also applied for obtaining of well defined oligosaccharides in a large scale.

Development and Characterisation of a Decellularised Bovine Osteochondral Biomaterial for Cartilage Repair

Hazel Fermor¹, Serena Russell², Sophie Williams², John Fisher² and Eileen Ingham¹

¹Faculty of Biological Sciences, iMBE, University of Leeds, UK

²School of Mechanical Engineering, iMBE, University of Leeds, UK, H.L.Fermor@leeds.ac.uk

INTRODUCTION

There is interest in the development of early intervention therapies for the repair of initial cartilage defects to prevent or delay the onset of osteoarthritis (OA). Current surgical treatments have variable success rates. The aim of this research is to produce an osteochondral graft from xenogeneic tissue with a similar extracellular matrix structure and composition to native human cartilage, retaining the natural biomechanical and biotribological properties, while removing the cells to ensure biocompatibility.

EXPERIMENTAL METHODS

Osteochondral pins (9 mm diameter, 12 mm deep, n=3) from the bovine medial femoral groove were decellularised using a process adapted from the work of Stapleton *et al.*¹. Tissue was analysed by histology using haematoxylin and eosin (H&E). DNA was extracted from tissues and isolated using Qiagen kits, then quantified using a nano spectrophotometer. Cartilage glycosaminoglycan (GAG) content was quantified following digestion with papain using the dimethylmethylene blue assay. Collagen content was assessed by quantification of hydroxyproline following acid hydrolysis using the p-dimethylamino benzaldehyde assay. Osteochondral pins were compressed using an indenter with a load of 0.8 N for 1 hour to determine cartilage deformation. Initial biocompatibility testing was performed to determine biomaterial cytotoxicity by culturing with BHK cells for 48 hours. For each set of numerical data the mean and 95 % confidence limits were calculated. Group means were compared using the T-test following one-way analysis of variance (ANOVA). A p-value <0.05 was accepted as significant. Percentage data were transformed using arcsin prior to statistical analysis and were then back-transformed for presentation

RESULTS AND DISCUSSION

Decellularisation of bovine osteochondral pins resulted in removal of cell nuclei as visualised by H&E staining (Figure 1).

Figure 1: Native (a) & decellularised (b) bovine osteochondral tissues stained with H&E. Scale bar 500µm.

A 94 % reduction in DNA was achieved (native cartilage = $119.0 \pm 35.9 \text{ ng.mg}^{-1}$, decellularised = $7.0 \pm$

5.9 ng.mg^{-1} per cartilage wet weight, $p < 0.05$). The GAG content of the tissue was also significantly reduced (native = $261.1 \pm 29.3 \text{ µg.mg}^{-1}$, decellularised = $2.5 \pm 2.8 \text{ µg.mg}^{-1}$ per cartilage dry weight, Figure 2) and collagen content increased significantly as a proportion of tissue dry weight. Decellularised cartilage showed a significant increase in percent deformation (native = $30.4 \pm 7.6 / - 7.1 \%$, decellularised = $55.9 \pm 20.1 / - 21.2 \%$ deformation, $p < 0.05$, Figure 2). Decellularised bone was cytotoxic when cultured in contact with BHK cells. Increased wash cycles to improve scaffold biocompatibility lead to macro scale cartilage deterioration. Large osteochondral plates ($2 \times 4 \times 1 \text{ cm}$) decellularised using the same process showed reduced macro scale and histological cartilage damage compared to osteochondral pins.

Figure 2: DNA and GAG content and percentage deformation of native (n=5) and decellularised (n=3) cartilage \pm 95 % CL. * significant, $p < 0.05$ (ANOVA).

Decellularisation of bovine osteochondral tissues was achieved, however the biological/ biochemical composition of the scaffold ECM significantly differed from that of native cartilage. These changes resulted in reduced biomechanical properties. Furthermore, the decellularised bone was shown to be cytotoxic. Alterations to the decellularisation process revealed cartilage matrix deterioration, which was found to be reduced by minimising the cut edge to cartilage ratio by processing larger cuts of osteochondral tissues. Further optimisation of the decellularisation process is required to produce a clinically relevant osteochondral graft.

CONCLUSION

This study has increased knowledge and understanding of the effects of decellularisation on osteochondral tissues which will form the basis for future development of a bioactive, acellular, natural tissue engineered repair material for osteochondral lesions to prevent or delay the onset of osteoarthritis

INTRODUCTION- Hydrogels can be injected in situ in degenerated nucleus pulposus (NP) to mould precisely to the defect spaces, eliminating the need for invasive surgical procedures. N-acetylglucosamine (GlnAc) has been reported to increase GAG production by triggering the SMAD/MAPK pathway (1). This effect is seen up to a limited concentration after which the effect is reversed (2). The present study aimed to develop a regenerative medicine biomaterial platform consisting of silk hydrogel embedded with silk hollow microspheres loaded with GlnAc. The silk hydrogel will provide structural support to the degenerated tissue while the GlnAc released in a spatiotemporally controlled manner from the silk hollow microspheres will help increase GAG.

EXPERIMENTAL METHODS- Silk hollow microspheres were synthesized via template sacrificial technique by using polystyrene beads (3). The silk hydrogel was prepared by self assembly of 4% w/v solution at 37°C following ultrasonication. The rheological properties of the hydrogels were studied using a AR2000 instrument (TA instruments, USA). ADSCs were cultured in high glucose DMEM with 10% FBS & 1% PS. Bovine IVDs were isolated and digested by injecting 0.15 mL of collagenase type II (10 g/L) for 18 h at 37 °C. The discs were injected with silk hydrogel system and mechanically tested with a Zwick-Roell mechanical tester.

RESULTS AND DISCUSSION- The synthesized silk hollow microspheres through template sacrificial method had a low polydispersity index (0.2) and were significantly stable at varied pH and ionic strength range. The silk hollow microspheres showed no adverse effects on the cell viability of ADSCs as studied by alamarBlue®, CytoTox 96® and Live/Dead® cell assay.

Fig. 1. a) Morphological analysis of silk hollow microspheres via SEM and b) & c) shows stability of the microspheres under varied ionic strengths & pH respectively.

The rheological properties of the silk hydrogel system demonstrated its injectability at RT withstanding the high ionic strength conditions inside the IVD (Fig. 2A).

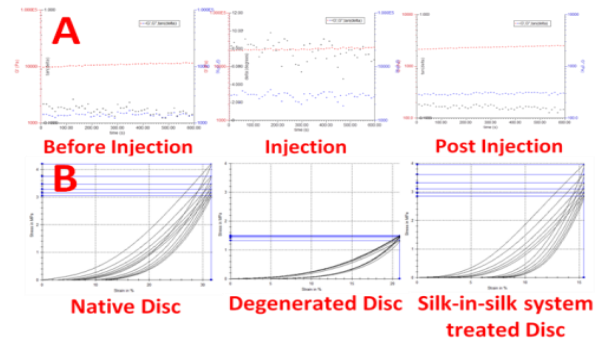

Fig.2. A) Rheological analysis showing the injectability of silk-in-silk hydrogel system. The system restores its native structure and rheological properties within 10 minutes of injection. B) Panels show average stress vs strain data for IVDs showing restoration of mechanical properties of the degenerated discs after injection with the silk-in-silk hydrogel system. Average data for IVDs containing PBS and also native IVDs are shown for comparison.

The loading efficiency of the silk hollow spheres with GlnAc was found to be >60% while a slow & steady release of the same was observed for 15 days. The static cyclic compressive testing showed a near complete restoration of the compressive properties of the IVDs (Fig. 2B). The seeded ADSCs showed a statistically significant increase in GAG and collagen production under a controlled release of GlnAc from the microspheres (Fig 3).

Fig. 3. GAG (A) and Collagen (B) estimation of silk hydrogels after 11 and 21 days. Values normalized to wet weight of the constructs.

CONCLUSION- The silk-in-silk hydrogel system through controlled release of GlnAc can help increase proteoglycan production while providing mechanical support.

INTRODUCTION

Because of the greatly enhanced risks of osteoarthritis after meniscectomy, meniscus replacement has been advocated in cases of extensive meniscal damage or after total meniscectomy¹. Autogenous and allogeneous materials have been considered for this replacement as well as synthetic scaffolds. In the native meniscus, circumferentially oriented collagen fibre bundles allow load transfer through hoop stress and whilst a number of previous scaffold designs have included fibre reinforcement²⁻⁴ they have differed significantly from the native meniscus chemistry. The authors have previously considered the use of aligned collagen fibres in the reinforcement of collagen – chondroitin-6-sulphate (C6S) structures for load-bearing soft tissues such as tendon⁵ and a modified version may be used for meniscal replacement.

EXPERIMENTAL METHODS

Samples consisted of collagen-C6S porous structures reinforced with collagen fibre bundles produced through a semi-continuous extrusion process⁵. As previously⁵, collagen fibres were added to the collagen-C6S slurry before a lyophilisation process was applied to the composite sample. The nature of fibre reinforcement was investigated with number of fibre bundles and prior cross-linking of the fibre bundles both being considered. A custom designed anatomically shaped mould was used, with rectangular cross-section samples of equivalent volume also produced for mechanical analysis. SEM (JEOL 820) and X-ray Microtomography (skyscan1072) were used to characterise fibre integration and pore structure. Quasi-static tensile tests were carried out parallel to the fibre alignment and compression tests perpendicular to the fibre orientation (Instron 3343). As an initial indicator of cell response, scaffold sections were seeded with human meniscal cells previously cultured for 3 weeks (with ethical approval). After 7 days, samples were stained with Calcein AM.

RESULTS AND DISCUSSION

Meniscus shaped samples were produced successfully with circumferentially aligned fibre reinforcement. A combination of bundles with and without cross-linking prior to addition of the matrix slurry was found to optimise mechanics and pore structure. Cross-linked fibres retained their dense structure during freeze-drying and provided mechanical strength, whilst the significant porosity formed within and around the non-cross-linked fibres offered potential for aligned tissue regeneration as well as aiding compressive characteristics. As *Figure 2* demonstrates, a porous structure was formed around the reinforcing fibres.

Cells were shown to infiltrate and adhere in vitro (*Figure 3*). With 2 cross-linked and 1 non-cross-linked fibre bundle a compressive modulus of in excess of 80kPa and a load to failure of close to 120N was achieved. Although inferior to the mechanics of the native menisci, the scaffold is not designed to be a

Figure 2: (a) photograph demonstrating anatomical shape, (b) SEM micrograph, and (c,d) 3D reconstruction of a small section of scaffold

permanent meniscal replacement; but a template for the regeneration of native tissue. The mechanical properties are sufficient to ensure a stable implant, and impart to at least some degree the biomechanical functions of the natural meniscus whilst cellular infiltration and tissue regeneration occurs. Additional work investigating the scaffolds in combination with Platelet rich plasma (PRP) also appears promising⁶

Figure 3: Calcein AM staining of cells adherent on the collagen fibre

CONCLUSION

Anatomically designed meniscal implants have been created with collagen fibres mimicking the circumferentially aligned fibres in the native meniscus. By combining collagen fibres with and without cross-linking, a pore structure has been produced suitable for cell infiltration and mechanical properties are sufficient to ensure implant stability and offer some of the biomechanical advantages of the native meniscus.

"Nonswellable" hydrogel without mechanical hysteresis

Hiroyuki Kamata¹, Ung-il Chung^{1,2}, and Takamasa Sakai¹

¹Department of Bioengineering, School of Engineering, University of Tokyo, Japan, kamata@tetrapod.t.u-tokyo.ac.jp

INTRODUCTION

Hydrogels are three-dimensional polymer networks that contain a large amount of water inside. Certain hydrogels can be injected in solution and transformed into the gel state with the required shape. Despite their potential biomedical applications, the use of hydrogels has been severely limited because all the conventional hydrogels inevitably "swell" under physiological conditions, which drastically degrades their mechanical properties¹. Our strategy to achieve a robust hydrogel that can operate under physiological conditions is based on the control of swelling by the introduction of thermoresponsive segments—which collapse above a certain critical temperature because of predomination of hydrophobic interactions—into the polymer network. We designed and fabricated hydrogels composed of tetra-armed hydrophilic and thermoresponsive polymer units.

EXPERIMENTAL METHODS

Hydrogels comprising of thermoresponsive segments were prepared by mixing aqueous solutions of tetra-armed hydrophilic and thermoresponsive polymers that were synthesised via an anionic ring-opening polymerization (water content: ~ 95%) (Fig. 1), where the thermoresponsive segment ratio was defined as r_{th} . The hydrogels were immersed in Dulbecco's Phosphate Buffered Saline (D-PBS), and their equilibrium swelling ratio (Q) was measured. Elongation and compression tests were performed using the samples equilibrated under physiological conditions (i.e., in D-PBS at 37°C).

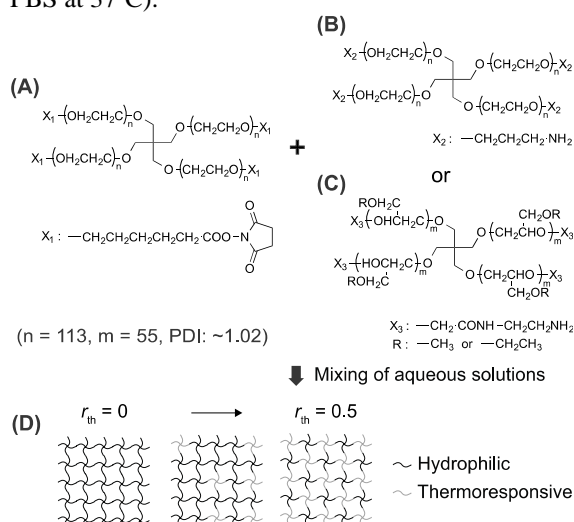

Fig. 1. Schematic of the thermoresponsive hydrogel system. (A) Hydrophilic tetra-armed poly(ethylene oxide) with active ester end-groups. (B) Hydrophilic tetra-armed poly(ethylene oxide) with amino end-groups. (C) Thermoresponsive tetra-armed poly(ethyl glycidyl ether-co-methyl glycidyl ether) with amino

end-groups. (D) Polymer networks composed of hydrophilic (black) and thermoresponsive (gray) polymer units where r_{th} represents the thermoresponsive segment ratio.

RESULTS AND DISCUSSION

The Q values under physiological conditions depended on r_{th} , while the hydrogel with $r_{th} = 0.4$ maintained its initial shape ($Q \sim 100\%$ = "nonswellable" hydrogel) (Fig. 2). The hydrogel composed only of hydrophilic polymers ($r_{th} = 0$, conventional hydrogels) endured 7-fold elongation in the as-prepared state. However, the swollen hydrogel failed at 2-fold elongation. In stark contrast, "nonswellable" hydrogel endured 7-fold elongation even in its equilibrium state under physiological conditions. Additionally, "nonswellable" hydrogel exhibited no mechanical hysteresis against a repetitive deformation and endured a compressive stress up to 60 MPa.

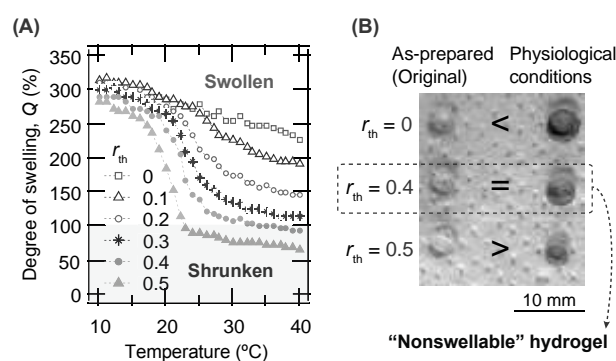

Fig. 2. Swelling behaviour of hydrogels in D-PBS. r_{th} represents the thermoresponsive segment ratio. (A) The swelling ratio (Q) as a function of temperature; $Q = V/V_0 \times 100$, where V is the volume of the samples in the equilibrium-swollen state at each temperature, and V_0 is the initial volume of the samples (i.e., before swelling). (B) Photos of the samples that exhibit different swelling degrees depending on r_{th} . The transparent hydrogels were coloured only for visibility.

CONCLUSION

Our results demonstrate that the swelling suppression of hydrogels helps maintain their initial shape and mechanical properties under physiological conditions². The hydrogel reported herein may constitute scaffolds for cartilage, which is exposed to a high mechanical overload.

A Collagen-Based Multimodal Delivery System Provides Therapeutic Factors as well as Physical Support for Treatment of Spinal Cord Injury in the Rat

R. Ronan^{1,2}, H. Kraskiewicz¹, B. Breen¹, T. Sargeant³, A. Pandit¹, S. McMahon²

¹Network of Excellence for Functional Biomaterials, ²Anatomy, National University of Ireland, Galway, Ireland;

³Covidien, 60 Middletown Avenue, North Haven, Connecticut 06473, United States; rachel08ronan@gmail.com

INTRODUCTION

Following injury to the spinal cord (SC) multiple biological responses occur, subsequently creating an environment which is inhibitory to axon growth, and which previous therapeutic attempts have failed to overcome. Biomaterial therapies are a promising option as they provide a 'bridge' through the inhibitory environment and can be functionalised, for example with therapeutic factors, which can then target specific aspects of the injury¹. Such therapeutic factors may target the inflammatory response e.g. interleukin-37 (IL-37) or provide support to neurons e.g. neurotrophin 3 (NT3). It was hypothesised that a dual delivery system² (Fig. 1A) could be used to both provide a 'bridge' and to deliver NT3 &/or IL-37 thus reducing the impact of the principle features of the injury, and promoting functional recovery after a hemisection SC injury in the rat. To examine this, lesion size, host response, glial scar and neuronal outgrowth across the lesioned area were quantified, and recovery of motor function was assessed.

Figure 1 Experimental design (A) A novel delivery system of injectable collagen hydrogel with IL-37 and NT3 loaded collagen hollow-spheres. (B) The cord was hemisectioned in the sagittal midline at T9 and hydrogel was applied immediately. (C) Summary of experimental groups. Sham group received laminectomy surgery only.

EXPERIMENTAL METHODS

Injury and application of treatment: 120 adult female Sprague-Dawley rats were anaesthetised and a T8 – T10 laminectomy performed to expose the cord. Injury condition and treatment were applied as shown in Fig. 1 B and C respectively.

Motor recovery analysis: Basso-Beattie-Bresnahan (BBB) locomotor rating scale was used to assess hind-limb motor function. Animals were assigned a score from 0-21 for each hind-limb at 1, 4 and 6 weeks post surgery, based on their movement in an open field.

Quantification of lesion size: Masson's trichrome histological stain was used to define the lesion area and to measure the change in lesion dimensions in response to treatment/over time.

Assessment of cellular responses: Anti-GFAP (glial fibrillary acid protein) and anti- β III tubulin were used to visualise glial scar and neuronal growth into the lesion. The host response was assessed by examining changes in the distribution and activity of macrophages. Both light and fluorescence images were obtained using the

Olympus Varioskan digital slide scanner. Statistical analysis involved one way ANOVA and Tukey's multiple comparison test.

RESULTS AND DISCUSSION

BBB analysis demonstrates an improvement in motor function across all treatment groups with hydrogel only, hydrogel + IL-37 and hydrogel + NT3 groups performing best. Improvement primarily occurs between weeks one and four. Histological assessment of SC sections shows a change in lesion size and shape over the 6 week study in all groups, with NT3 and/or IL-37 treatment showing greatest benefit (Fig.2).

Fig.2. The size and shape of the lesion changes over time. Masson's trichrome stained images of cords from animals treated with hydrogel containing IL-37 at 1 week (A), and 6 weeks (B). Collagen is stained green while nuclei and cytoplasm are stained black and purple respectively. Scale bar = 500 μ m. Yellow line marks lesion borders. After six weeks neuronal growth into the gel and lesion area is evident from β III tubulin immunoreactivity (Fig. 3). A reduction in glial scar formation is to be seen in hydrogel treated animals in comparison to hemisection controls. The immune response to injury is also altered over time and in response to treatment.

Fig. 3. Glial scar around the lesion border, highlighted within yellow outline, and neuronal ingrowth into the lesion. Images from hydrogel + NT3 treatment group at (A) 1 week (B) 6 week. Scale bar = 500 μ m.

CONCLUSION

Characteristics of SC injury including lesion size and shape, immune, glial and neuronal responses were quantified, and functional recovery was determined. Results suggest that collagen hydrogel is beneficial after hemisection injury to act as a platform both for drug delivery and on which axons can grow.

INTRODUCTION

Material induced biological responses are a fundamental research area that has implications in all technologies that require a cell/protein to come into contact with a synthetic substrate. Recent research has proven that cells can sense and respond to stimuli at the nanoscale. In addition to responding to stimulus introduced by changes in nanotopography, we have also proven that changes in the distribution of chemical groups at the nanoscale are a powerful tool for controlling protein and cell responses¹.

Here we present data relating to the sub-micron properties of a range of silane modified substrates, and how specific combinations of chemistry, energy and nanotopography can be used to effectively control stem cell responses. The data presented within this paper will emphasise how a combinatorial approach to substrate/interface design is a pre-requisite for effective control of protein/cell interactions. In addition we will present data relating to how control of protein adsorption and subsequent matrix formation on the highly defined synthetic substrates is a key factor in determining subsequent cellular responses.

EXPERIMENTAL METHODS

A range of $-NH_2$ and $-CH_3$ presenting chemistries were developed and characterised. Full disclosure of surface modification techniques is protected by IP. Resultant surfaces were characterised using X-ray Photoelectron Spectroscopy (XPS), Water Contact Angle (WCA), Atomic Force Microscopy (AFM) and Scanning Electron Microscopy (SEM). Test substrates were cultured in contact with varying concentrations of protein solutions, fibronectin (5-100 $\mu g/ml$) and vitronectin (2-200 $\mu g/ml$), protein adsorption profiles were visualised using immunohistochemistry and confocal microscopy. Commercially available human mesenchymal stem cells (hMSC, Lonza UK), were cultured in contact with test substrates in basal medium (Lonza UK) for time periods up to and including 28 days. Initial cell adhesion was characterised, fluorescent imaging of vinculin and actin and PCR arrays for cell adhesion (Qiagen), providing information regarding up regulation of selected integrins. In addition the phenotype of the adhering cell population was analysed using immunohistochemistry for the qualitative evaluation of proteins of interest i.e. STRO1, nucleostemin, fibronectin, collagen I and osteocalcin. The ability of cells to produce a calcified extra cellular matrix was also evaluated using von Kossa staining and light microscopy.

RESULTS AND DISCUSSION

Experimental evidence supported the hypothesis that combinations of optimised surface chemistry and

nanotopography increased the efficiency of previously reported material induced cell responses. $-CH_3$ modified substrates with a controlled nanotopography (peak-peak distance of $\sim 280nm$) was optimal for the formation of a cohesive fibronectin network and subsequent maintenance/enhancement of a stem cell phenotype.

Figure 1: Fibronectin (5mg/ml) adsorption profile at 1 hour on a $-CH_3$ modified substrate. (B) Peak profile of $-CH_3$ modified substrate generated by AFM, showing a peak to peak separation distance of $\sim 280nm$.

In contrast optimised sub-micron properties on $-NH_2$ modified substrates (peak height greater than 100nm) resulted in substrates that had the ability to absorb phosphate from solutions directly onto the surface and resulted in a highly osteogenic substrate that had the capacity for matrix remodelling.

Figure 2: hMSC cultured in contact with $-NH_2$ modified substrates and stained for osteocalcin at 14 days (A) and (B) von Kossa at 28 days. There was extensive evidence of matrix remodelling on optimised substrates.

Changes in bulk surface chemistry can enhance the potential of specific proteins to adsorb to a surface, but subtle changes in the associated nanotopography of bulk chemistry can be used to direct matrix formation and subsequent cell adhesion on a much improved scale. Control of material parameters must be considered at the sub-micron scale to realise the potential of material induced biological responses.

INTRODUCTION

Magnetic nanoparticles have been intensively studied for different applications: electronic industry, biomedical devices, also as contrast agents in Magnetic Resonance (MR) and drug delivery agents, as a promising therapy for tumour treatment¹⁻². The latter called hyperthermia consists in the increase in temperature in the tumour induced by the magnetic nanoparticles upon application of an external magnetic field. Therefore it is desirable to obtain the highest heating power with the fewer amount of nanoparticles. Different ferrite nanoparticles (MFe_2O_4 , $M=Fe, Co, Ni, Zn$, etc) have been used for this purpose³⁻⁴. Their properties depend on nanoparticles size, structure and magnetic properties and on the magnetic field applied. On the other hand, there are limited reports on the toxicity of ferrite nanoparticles. In the present work the synthesis, characterization, magnetic properties, magnetothermic behaviour and *in vitro* cytotoxicity of zinc ferrite nanoparticles was studied.

EXPERIMENTAL METHODS

Synthesis of Zn-ferrite nanoparticles

The synthesis of magnetite (Fe_3O_4) was carried out by a precipitation method using $FeSO_4 \cdot 7H_2O$ and sodium hydroxide concentrations (0.074, 0.104, 0.134, 0.164, 0.194 M), and zinc ferrites ($Zn_xFe_{(3-x)}O_4$) were synthesized by a similar method but using 0.194 M of sodium hydroxide and potassium nitrate as oxidant agent. The particles were characterized by XRD, SEM, magnetization measurements and magnetothermic experiments using a magnetotherm system (NanoTherics, Ltd), at different frequencies from 108.7 kHz to 333.3 kHz and different magnetic fields from 2 to 10.7 kA/m, for nanoparticles concentrations between 2 to 20 mg/mL.

Cell Culture

VERO immortal cells were used as cell line, and the viability studied was carried out using CellTiter 96® Aqueous One Solution Cell Proliferation Assay (Promega®). 3000 cells/well were seeded in 96 well plates, for 48 h and exposed to two concentrations (10 and 100 µg/mL) of three different ferrite nanoparticles. Experiments were performed by triplicate. SEM analysis of the cell/nanoparticles culture was carried out.

RESULTS AND DISCUSSION

The structural characterization of the samples revealed that the magnetite and Zn-ferrite structure was obtained. Depending on the synthesis conditions different particle size and morphology was obtained. Nanoparticles size range from 50 nm to 90 nm was observed.

The magnetic measurements showed that all the samples present a superparamagnetic behaviour, and the saturation magnetization varied from 60 to 90 Am^2/kg , depending on Zn substitution on the ferrite (Fig. 1a)

Fig 1 a. Magnetization curves for different Zn substitutions in ferrite samples. b. Temperature vs. time for different Zn content.

The magnetothermic experiments of magnetite samples and $Zn_xFe_{3-x}O_4$ tested at different frequencies (108.7-333.3 kHz) and different magnetic fields (2-10.7 kA/m) showed an increase temperature gradient with the increase in magnetic field, frequency and Zn content (figs. 1a,1b). It can be observed that a high magnetic field (10.67 kA/m) and low frequency (108.7 kHz) a temperature of 42°C can be reached in 80 s using a concentration of 20 mg/ml for the highest Zn substitution. The biological acceptable limit of frequency and magnetic field ($H \cdot f$) is 5×10^9 A/m.s⁵, therefore the parameters used in the present work are below this limit (1.16×10^9 A/m.s) within a safe range. The biocompatibility *in vitro* studies showed protrusion of filipodia interacting with the nanoparticles, no cytotoxicity effects of iron oxide nanoparticles with and without Zn substitution was obtained.

CONCLUSION

Ferrite nanoparticles has been synthesized with different Zn content, showing a high magnetization saturation and magnetothermic response, depending on the applied magnetic field and frequency used. No citotoxic effects were observed; therefore they can be considered as promising materials for magnetic hyperthermia therapy.

INTRODUCTION

Suboptimal osseointegration can lead to failure of orthopaedic implants that would necessitate revision surgery. In order to maximise the biological fixation of orthopaedic implants, it would be advantageous to improve the bioactivity of bioinert load-bearing materials such as titanium. Topographical surface patterning offers the potential for this, and we have previously demonstrated the efficacy of 15 nm Ti high nanopillars for osteogenesis [1, 2]. In this study, these osteogenic pillar-like features were combined with micron-scale pits, to examine the response of human mesenchymal stem cells (MSCs) to these osteogenic cues.

EXPERIMENTAL METHODS

Nanopillar-like features were produced in Ti using a block copolymer masking approach [3], and micromachining was employed to produce the micropits. MSCs were cultured for 3 days on the surfaces and immunostained for focal adhesions (FAs), and FAs were quantified using image analysis. The bone marker osteocalcin was examined on these surfaces after 21 days of culture. Microarrays were used to assess the changes in relative transcript abundance between the cells on planar control and micronanopatterned Ti surfaces, including the assessment of small untranslated RNAs such as miRNAs. Ingenuity Pathways Analysis (IPA) was used to examine the functional networks of likely interactions between the gene products.

RESULTS AND DISCUSSION

The micro-nanopatterned substrates modulated FAs, and enhanced deposition of osteocalcin was also noted on the micro-nanopatterned Ti surfaces (Figure 1A). A number of osteogenic transcripts, including transcripts encoding bone morphogenic proteins (BMPs), miRNAs involved in the regulation of BMP signalling and differentiation, and 14 other small regulatory RNAs, involved in processes such as transcript editing, were up-regulated in MSCs cultured on the topographically modified Ti. A high-scoring network of likely interactions between some of the highlighted gene products, generated using IPA, is shown in Figure 1B. Importantly, the micro-nanopatterned topography could also be produced on the curved surface of Ti rods.

Figure 1A: Cells cultured on micronanopatterned Ti (right image) tended to form clusters around the micropits and express more osteocalcin than on planar controls (left image). Red – actin, green – osteocalcin, blue – DNA. Bar: 50 μ m. 1B: High-scoring IPA network illustrating some transcripts that were up-regulated (such as a BMP and a miRNA; red) or down-regulated (green).

CONCLUSION

The micro-nanopatterned surfaces were osteogenic, showing enhanced expression of osteogenic transcripts, small regulatory molecules associated with differentiation, and increased levels of bone markers. The micro-nanopatterned surfaces showed promise for use in orthopaedic implants.

INTRODUCTION

Bisphosphonates, e.g. sodium alendronate (Aln), administered orally are considered as the first line treatment of osteoporosis¹. Aln amino side chain demonstrates strong inhibitory effect of osteoclast-mediated bone resorption and blocks hydroxyapatite loss². Unfortunately, the drug is characterized by low bioavailability (<1% when administered orally) and causes many side effects like fever or ulcers. Hence, it seems to be promising to replace systemic treatment by efficient local delivery of Aln³. Thus, in our study we propose injectable drug delivery system consisting of Aln-loaded nanoparticles suspended in a biocompatible hydrogel (gellan gum) and evaluate their biological performance *in vitro* in contact with osteoblast- and osteoclast-like cells.

EXPERIMENTAL METHODS

Aln (Polpharma SA) was encapsulated in poly(L-lactide-co-glycolide) (PLGA, 85:15, Mn=80 kDa) nanoparticles (NP-Aln) via a double-emulsification/solvent evaporation technique. NP-Aln were characterized with dynamic light scattering (DLS), laser electrophoresis, scanning electron microscopy (SEM), atomic force microscopy (AFM); UV-vis spectroscopy (OPA reagent, 332 nm) was used to assess loading and encapsulation efficiencies. In order to obtain injectable drug delivery system, NP-Aln were suspended in gellan gum (GelzanTM, Sigma-Aldrich) and cross-linked with Ca⁺² (GG-NP-Aln). The systems obtained were evaluated with respect to injectability, drug release and morphology (SEM). Then, they were studied *in vitro* via an indirect way. Extracts from the samples (in culture media prepared at 37°C for 72 h) were examined on osteoblast-like cells (MG-63) and osteoclast-like cells (RAW 264.7 differentiated by RANKL) (5x10³ cells/well, 96-well plate). Proliferation, viability (MTS assay), different staining (Live/Dead, Hoechst-Texas red, acid phosphatase - AP, tartrate-resistant acid phosphatase - TRAP) were conducted. Moreover impedance measurements on xCELLigence analyzer were performed to test cell proliferation in real-time.

RESULTS AND DISCUSSION

DLS studies showed that size of the carriers ranged from 200 nm to 400 nm, and AFM confirmed their spherical shape. Laser electrophoresis demonstrated negative zeta potential. Results of solubilization revealed encapsulation efficiency of 70.3±4.9% and drug loading of 5.14±0.60%. Injectability studies of the systems showed that extrusion force from the standard

18G needle was lower than 30 N, the force increased with NP-Aln addition. Drug release studies of GG-NP-Aln showed short burst release followed by sustained release phase. MTS and Live/Dead assays showed that the systems were not cytotoxic. Osteoblast-like cells adhered and proliferated well in medium with GG-NP-ALN extracts (Fig. 1 A1, A2); cell growth measured by xCELLigence system was also not altered (Fig. 1 A3). AP and TRAP staining confirmed differentiation of RAW 264.7 cells to osteoclasts (Fig 1 B1, B2). Osteoclast-like cells growth was reduced when they were cultured in medium supplemented with Aln or extracts from GG-NP-Aln as compared to control (Fig. 1 B3). It proves that manufacturing procedure of GG-NP-Aln systems does not diminish antiosteoclast potential of Aln.

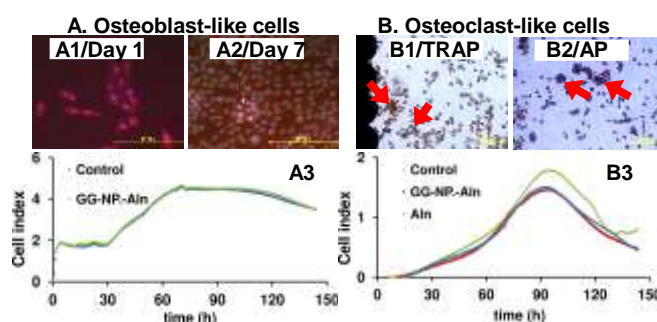

Fig. 1 Morphology of cells: osteoblast-like on day 1 (A1) and 7 (A2) (Hoechst-Texas red staining) and osteoclast-like after 7 days - TRAP staining (B1) and AP staining (B2) (red arrows show multinucleated giant cells - osteoclasts); Real-time dynamic monitoring of osteoblast-like cells (A3) and osteoclast-like cells (B3) proliferation using impedance xCELLigence analyzer in relation to control (pure media).

CONCLUSION

Our systems based on Aln-loaded PLGA nanoparticles suspended in gellan gum hydrogel matrix: i) were found to be injectable, ii) assured local sustained drug delivery, and iii) inhibited osteoclasts proliferation without affecting osteoblasts functions. The results show the promising potential of developed drug delivery systems for the local treatment of osteoporosis.

Bio-corrosion behaviour of chosen magnesium alloys from the Mg-Zn-Ca system

Katarzyna Kubok and Lidia Litynska-Dobrzynska

Department of Functional and Structural Materials,
Institute of Metallurgy and Materials Science Polish Academy of Sciences, Poland, k.kubok@imim.pl

INTRODUCTION

Magnesium alloys from the Mg-Zn-Ca system are attractive, because of their possible application as bioresorbable cardiovascular stents or orthopaedic implants. Magnesium alloys possess the density and Young's modulus close to that of cortical bone¹. The crucial issue is the precise control of corrosion rate, which is usually very rapid and connected with H₂ evolution. Alloying additions and their amount are among the most important factor influencing the corrosion behaviour. Therefore the wide range of Mg-3Zn-xCa wt.% alloys were examined in this study. The percentage addition of zinc was selected based on the literature review^{1,2}. Whereas calcium additions were selected due to our previous results³.

EXPERIMENTAL METHODS

Alloys of nominal composition presented in Table 1 have been prepared from Zn (99.999%), Ca (99.9%) and Mg (99.9%) under the argon atmosphere.

Tab. 1 Nominal compositions of investigated alloys

Alloy	Composition					
	wt.%			at.%		
	Mg	Zn	Ca	Mg	Zn	Ca
Pure Mg	99.9	-	-	99.96	-	-
Mg-3Ca	97	-	3	98.16	-	1.84
Mg-3Zn	97	3	-	98.86	1.14	-
Mg-3Zn-0.2Ca	96.8	3	0.2	98.74	1.14	0.12
Mg-3Zn-1Ca	96	3	1	98.24	1.14	0.62
Mg-3Zn-3Ca	94	3	3	96.97	1.15	1.88

Samples for immersion testing of 15 mm in diameter and 5 mm in thickness (total surface area = 3,14 cm²) were cut from cylindrical ingot. The specimens were polished and cleaned. The Hanks solution with calcium and magnesium was used as simulated body fluid in 37°C. The solution volume to surface area ratio was 28.6. pH was measured during the immersion test at different intervals. The corrosion products were removed using solution of 200g/l chromic acid with 10g/l silver nitrate in deionized water. The cleaned and dried specimens were weighted and the corrosion rate was calculated using formula:

$CR = \Delta W / (A \cdot t)$, where CR is the corrosion rate (mg/cm²/day); ΔW is the weight loss (mg); A is the original surface area exposed to the Hank's solution (cm²) and t is exposure time in hours. At least three samples for each alloys were assessed.

FEI ESEM XL30 with energy dispersive X-ray (EDX) has been used to observe the microstructure of all samples. The cross-sections (after 2 and 14 days of immersion) were observed in BSE mode and the surfaces without corrosion products in SE mode. Preliminary examination of phases in the as cast alloys has been done by XRD using Philips PW 1840 X-ray diffractometer. Different phases and their distributions

in the alloys were carefully investigated using transmission electron microscopy (Tecnai G2 F20 200 kV).

RESULTS AND DISCUSSION

Figure 1 shows cross-section of Mg-3Zn-0.2Ca and Mg-3Zn-1.0Ca after 48h of immersion in HBSS.

Fig. 1 SEM micrographs of a) Mg-3Zn-0.2Ca and Mg-3Zn-1.0Ca after 48 h of immersion

Mg-3Zn and Mg-3Zn-0.2Ca exhibit lower degradation rate than pure Mg. The corrosion rate of Mg-3Zn (~0.14 mg/cm²/day after 14 days) was similar to that reported by Kirkland *et al.* in MEM¹. Due to this fact results can be compared and considered even lower due to higher corrosion rate in HBSS than in MEM. The presence of high amount of Mg₂Ca phase in the Mg-3Ca and Mg-3Zn-3Ca alloy accelerates the corrosion rate up to ~7 mg/cm²/day after 14 days. On the other hand, the corrosion behaviour in Mg-3Ca and Mg-3Zn-3Ca alloys is inverse – in Mg-3Ca alloy the corrosion rate decreases with time while in Mg-3Zn-3Ca increases. The corrosion rate of alloy containing only ternary Ca₂Mg₆Zn₃ (Mg-3Zn-1Ca) is higher than that of pure Mg. In all cases, except for Mg-3Zn-0.2Ca pH after 7 days of immersion exceeds 10.0. For the Mg-3Zn-0.2Ca the pH value is ~ 9.0 after 7 days. The results connected to Mg-3Zn-0.2Ca and Mg-3Zn-1.0Ca alloys are very promising.

CONCLUSIONS

The corrosion rate can be tailored through precise control of alloying elements, type of phases and their distributions in the alloy. The further improvement of the corrosion rate may be obtained due to proper heat-treatment design.

INTRODUCTION

New developments in dental implantology are focused on bone-implant interaction to minimize complications or failure. One of the main drawbacks for metal implants is often due the inadequate interaction between materials and cells, leading to *in vivo* to foreign body reactions such as inflammation, infections, aseptic loosening, local tissue waste, implant encapsulation and thrombosis¹⁻³. The host response to a biomaterial is critical to determine the success of biomedical implants. A promising strategy is to anchor peptides to the metal surface due to their ability to stimulate cell bone response. The aim of this study was to generate and optimize the metal functionalization procedures and fully characterize each preparation step. Two activation methods were assessed by comparing contamination removal, hydroxyl groups (OH-act) formed on the surface, metal oxide ratio and changes in the chemical composition of the oxide layer. Then, three different organosilanes were employed as crosslinker for metal-peptide binding methods (CPTES, GPTES and APTES) and their metal coating capability was evaluated by measuring the amount of the metal bound Si and the stability of Si-O-Ti. Finally, covalent peptide immobilization of RGD, FRRRIKA and PHSRN and their mixtures was also investigated.

EXPERIMENTAL METHODS

Smooth CoCr alloys samples were bioactivated with either Oxygen Plasma (PO) or Nitric Acid (NA) and followed by silanization with CPTES, GPTES or APTES. These surfaces were then coated with different peptides as CGGRGDS, CGGPHSRN, CGGFHRRIKA, or mixtures of them (50/50): CGGRGDS + CGGPHSRN or CGGRGDS + CGGFHRRIKA). Non-treated CoCr alloys samples were used as control. Surfaces were characterized by contact angle measurements, X-ray Photoelectron Spectroscopy (XPS), Time-of-Flight Secondary Ion Mass Spectrometry (ToF-SIMS) and Zinc-complex Substitution Technique (ZT). The *in vitro* effect of modified surfaces was evaluated by cell adhesion assays, immunofluorescence and Scanning Electron Microscope (SEM). Mann-Whitney and Kruskal-Wallis statistical tests were used (p -value<0.05).

RESULTS AND DISCUSSION

The decrease in the CA values is associated with surface contamination removal as well as with the introduction of hydrophilic groups on the surface. XPS and ZT analysis showed that NA did not alter the $\text{Cr}^{n+}/\text{Co}^{n+}$ oxide ratios and a higher density of hydroxyl groups on the surface was observed. XPS analyses then confirmed that all strategies successfully immobilize peptides on the modified surfaces, showing a higher peptide density when APTES was used. Cell assays demonstrated an increase in density, morphology and area for mesenchymal cells when RGD motive (no- or combined) was covalently attached on the surface. (Figure 1).

Figure 1. Effect of modified surfaces using APTES as silane on cells adhesion.

CONCLUSION

The metal functionalization strategy applied in this study allowed to successfully attach covalently peptides on CoCr alloy surfaces. These remarkable results demonstrated that covalent immobilization of different peptides moieties with APTES onto CoCr alloys surfaces induced an improved cell response.

Bioactive Glasses to Stimulate Angiogenesis

Alejandro Gorustovich¹, Aldo R. Boccaccini^{2*}

¹Interdisciplinary Materials Group-IESIING-UCASAL, INTECIN UBA-CONICET, Salta, Argentina

^{2*}Institute of Biomaterials, University of Erlangen-Nuremberg, Erlangen, Germany aldo.boccaccini@ww.uni-erlangen.de

INTRODUCTION

Enhancement of the angiogenic potential of implantable tissue scaffolds is the focus of considerable research efforts in tissue engineering (TE) strategies¹. New concepts to stimulate and control bone regeneration or to develop bone TE constructs based on biomaterials are needed that take into consideration angiogenesis. New blood vessels bring oxygen, nutrients and growth factors as well as serve as a route for inflammatory cells and bone precursor cells to reach to the highly metabolically active regenerating tissue. Indeed, enhancing angiogenesis could be a viable therapeutic approach for accelerated/improved bone regeneration clinically². Increasing number of investigations are being reported documenting that specific compositions of silicate bioactive glasses (BGs), used in bone regeneration approaches, not only stimulate new bone growth but also their ionic dissolution products (IDPs) may act as angiogenic factor and induce increased vascularization when incorporated in TE scaffolds³. In this overview presentation a series of experiments that prove the angiogenic potential of BGs, including both in vitro and in vivo studies, will be discussed in detail.

EXPERIMENTAL METHODS

The most investigated material in angiogenesis and bone vascularization studies has been the classic 45S5 Bioglass system of composition (in wt.%): 45% SiO₂, 24.5% Na₂O, 24.5% CaO and 6% P₂O₅. The material has been considered in particulate form and as filler and coating of biodegradable polymers to form composite scaffolds. More recently, 3D Bioglass-based scaffolds fabricated by the foam replica method^{4,5} and sol-gel derived foams⁶ have been considered in angiogenesis and vascularization studies. In addition, a series of novel bioactive glass compositions and ion-doped silicate systems have been investigated to assess angiogenic effects⁷. As it has been established that boron (B) may perform functions on angiogenesis and osteogenesis, the controlled and localized release of B ions from BG is expected to provide promising angiogenic effects.

RESULTS AND DISCUSSIONS

In vitro results showed that IDPs from 45S5 BG particles (< 5 µm) containing B₂O₃ (2 wt%) (labelled 45S5.2B) have a robust proangiogenic activity on human umbilical vein endothelial cells (HUVECs)⁸. Compared to controls, cell proliferation, migration, tubulogenesis and pro-angiogenic cytokines release of HUVECs were statistically significantly increased by conditioned media containing the IDPs of 45S5.2B BG. It has also been found that IDPs from 45S5.2B based scaffolds stimulated angiogenesis in the quail embryo

chorioallantoic membrane (CAM) bioassay (Fig. 1). Importantly, the angiogenic response reached the same extent as that obtained by bFGF. These findings are relevant to vascularized bone tissue engineering because IDPs from 45S5.2B BG are confirmed to act as an inorganic angiogenic agent serving as an alternative to expensive and potentially risky growth factors.

Fig. 1. Angiogenic CAM response at 5d after treatment. Orig. Mag. X35

CONCLUSIONS

The results indicate that 45S5.2B-based scaffolds are a promising candidate for bone TE due to their bioactivity and potential enhanced angiogenic effects provided by B. The results are in agreement with an increasing number of studies reporting the angiogenic properties of ion doped BGs for vascularized bone regeneration. The specific effects of different IDPs on vascularization are the subject of increasing research efforts and their understanding promises to have a significant impact on the application of BGs in bone tissue engineering.

INTRODUCTION

Among the various biomaterials used as bone substitutes or as prosthesis coatings in orthopedic surgery, bioactive glasses have attracted considerable interest^{1,2}. When in contact with living tissues, dissolution and precipitation take place at the material / biological medium interface, and this leads to the formation of a phosphocalcic layer. This apatite-like layer is used as a mineralization site for bone cells and finally allows an intimate chemical bond between the glass and the bone. A fine control of bioactivity can be achieved by using soft chemistry routes to tailor the morphology and the texture of such porous bioactive glasses. Pore size can span several orders of magnitude from the nanometer to the millimeter. Each level of porosity (meso, macro,...) could then have biological usefulness, like for drug delivery, vascularization of the implant, or cell adhesion for tissue engineering. With this respect, mesoporous, macroporous and glass foams have been prepared.

EXPERIMENTAL METHODS

Mesostructured glasses (Fig 1a) have been prepared by using surfactant as directing agent whereas polystyrene opals were used as template for the production of macroporous glasses with different pore size (Figure 1b). Finally using a surfactant and adapted dispersive equipment, a air/liquid foam has been used as template to obtain monolithical glass foams (Fig 1c).

All samples have been characterized using a various set of techniques including gas sorption, SAXS, thermoporosimetry, helium pycnometry and SEM/TEM microscopies.

RESULTS AND DISCUSSION

The control of the pore size and pores organization is demonstrated for meso and macro porous glasses. Glass foams exhibit a multiscale porosity with a high fraction of void making these materials attractive for tissue engineering applications.

Finally interactions between acellular biological medium and the different glasses have been studied for different delays. At each time period, quantitative chemical maps of samples were recorded with a micrometer resolution using Particle Induced X-ray Emission coupled to Rutherford Backscattering spectroscopy (PIXE-RBS)³. This technique allows monitoring spatial and chronological evolutions of elemental concentrations, thanks to measurements with an excellent sensitivity (10^{-6} g/g). The influence of porosity on the bioactivity has been determined. Comparison of mesoporous glasses exhibiting or not

spatial ordering is provided. Determining parameter for the biomineralization onto macroporous glasses is found to be the size of the interconnection window and a criterion is proposed for the homogeneous nucleation for HAp in glass foams.

Figure 1: a) TEM image of a mesostructured bioactive glass (scale bar 20 nm), b) SEM image of a macroporous sample (scale bar 1 μ m) and c) picture of a monolithical glass foam (scale bar 2cm).

Bioactive Glass-Ionomer Cements for Bone Tissue Regeneration

Paul V. Hatton¹, Altair Contreras¹, Felora Mirvakily¹, Yulia Ryabenkova¹, Ian Brook¹, Aileen Crawford¹, Robert Moorehead¹, Andrew Rawlinson¹, Christine Freeman¹, Ian M. Reaney², and Cheryl Miller¹

¹Bioengineering & Health Technologies Research Group, School of Clinical Dentistry, and ²Department of Materials Science and Engineering, University of Sheffield, UK paul.hatton@sheffield.ac.uk

INTRODUCTION

Glass-ionomer bone cements have been used successfully in otological surgery for over 20 years. They have, however, been restricted to use in a relatively narrow range of surgical procedures due to the release of aluminium ions that interfere with the mineralisation of new bone tissue¹. There have therefore been numerous attempts to replace alumina in the parent glasses with other metal oxides (including iron, zinc and magnesium) to produce glass-ionomer cements that could be used in a wider range of clinical applications, but none of these have been sufficiently successful to justify clinical evaluation. The aim of this research was therefore to investigate whether classical bioactive glass compositions² could form the basis for usable cements that retained the osteoconductive properties of the parent glasses.

EXPERIMENTAL METHODS

Bioactive glass compositions were prepared by melting to obtain final molar compositions summarised below (Table 1). The amorphous nature of the glasses was investigated using X-ray diffraction (XRD), and the post-melt compositions were determined using X-ray fluorescence (XRF). Glasses were milled and sieved to obtain particles of <45 µm. Cements were prepared by mixing with poly(acrylic acid) with mean molecular weights of 45,000 (First Scientific GmbH) or 52,000 (Advanced Healthcare Ltd.) and distilled water or aqueous solutions of phosphoric acid. Working and setting times were measured using either a Gilmore needle or rheometer. Aqueous stability was determined by storage of cement discs (5 mm x 1 mm) in distilled water. The *in vitro* and *in vivo* biocompatibility of the novel cement based on 45S5 bioactive glass powder was further investigated using cultured rat mesenchymal stromal cells (MSCs) and a healing defect (1 mm) in the midshaft of the rat femur respectively.

Example number	Composition (mol%)				
	SiO ₂	Na ₂ O	CaO	P ₂ O ₅	SrO
1	46.1	24.4	26.9	2.6	0
2	50.9	22.1	25.6	1.3	0
3	50.3	21.9	25.3	2.6	0
4	46.1	24.35	24.2	2.6	2.7

Table 1. Pre-melt bioactive glass compositions used to prepare cements.

RESULTS AND DISCUSSION

All pre-melt compositions summarised in Table 1 formed glasses, with no crystalline phases detected by XRD. Glass powders were all capable of forming a setting cement system with poly(acrylic acid), and the substitution of water with phosphoric acid solution accelerated the setting reaction and appeared to improve

the stability of the cement in water. All cements reported here were stable in distilled water at 37 °C for a period of at least six months. Cell culture studies showed a reduction in the metabolic activity of MSCs cultured in the presence of cements based on 45S5 bioactive glass compared to Thermanox® reference materials, but it was also determined that MSCs could be cultured successfully for up to 21 days in the presence of this cement. *In vivo* investigation demonstrated the formation of a direct bone-implant interface after 4 weeks (Figure 1), suggesting rapid osseointegration with no evidence for the mineral defect reported previously for conventional glass-ionomer bone cements¹.

Figure 1. Formation of direct bone-implant interface (arrowed) after 4 weeks implantation of a bioactive glass-ionomer cement (BGC) prepared using 45S5 bioactive glass and poly (acrylic acid).

CONCLUSION

It was concluded that, despite the absence of alumina in the parent glass composition, it was possible to prepare a glass-ionomer cement using only bioactive glass compositions in combination with poly (acrylic acid), and cement formation was further improved through addition of phosphoric acid. The new cement based on 45S5 bioactive glass was biocompatible *in vitro*, and encouraged substantial bone tissue regeneration *in vivo*. These promising new materials have significant potential for use as cements, and also as pre-set graft substitutes or scaffolds for bone tissue regeneration³.

Well Ordered Mesoporous Bioactive Glasses for Bone Tissue Engineering and Drug Delivery

Chengtie Wu

State Key Laboratory of High Performance Ceramics and Superfine Microstructure, Shanghai
Institute of Ceramics, Chinese Academy of Sciences, Shanghai, China, chengtiewu@mail.sic.ac.cn

INTRODUCTION

As a new class of bioactive materials for bone regeneration, ordered mesoporous bioactive glasses (MBG) have attracted much attention in recent years. Compared with traditional bioactive glasses, the typical features of MBG are as follows: (1) They have highly ordered mesoporous channel structure (2-20nm), high surface area and pore volume; (2) Since the nanostructure is significantly improved, MBG have greatly enhanced apatite-mineralization ability and degradation; (3) MBG can be used to delivery drugs with its high specific surface area and pore volume [1-5]. The aim of this study is to explore the potential application of MBG for bone tissue engineering and drug delivery.

EXPERIMENTAL METHODS

MBG powders were prepared through chemical templating methods. MBG/polymer composites were prepared by using freeze drying methods. MBG scaffolds were prepared by polyurethane sponge template and 3D-printing technology. The functional effect of different elements and surface modification of MBG on the in vitro osteogenic differentiation of bone marrow stromal cells (BMSCs) and in vivo osteogenesis was systematically studied. The effect of drug delivery of MBG on the functional effect on the in vitro osteogenesis was investigated.

RESULTS AND DISCUSSION

MBG powders can improve the in vitro and in vivo osteogenic properties of polymer biomaterials such as PLA and silk protein. With the incorporation of functional elements into MBG scaffolds, the osteogenesis and potential angiogenesis were significantly enhanced. Moreover, with special component, we can obtain magnetic scaffolds, which may be used in hyperthermia to heal bone tumour. By using 3D-printing, the pore size of morphology of MBG scaffolds can be effectively controlled, which leads to improved mechanical strength. MBG scaffolds can be used for drug/growth factor carrier to load and release DEX, DMOG and VEGF. It is proved that the delivery of drug and growth factor significantly stimulated the osteogenesis and angiogenesis of BMSCs for bone tissue engineering.

CONCLUSION

MBG significantly improves the osteogenic differentiation of BMSCs and in vivo bone regeneration ability. MBG can be used as drug/growth factor carrier to accelerate the osteogenic differentiation of BMSCs. Therefore, MBG can provide an excellent platform for bone tissue engineering and drug delivery system.

Glass Fiber-Reinforced Composite Cranial Implant with Bioactive Glass

Pekka K. Vallittu

Department of Biomaterials Science and Turku Clinical Biomaterials Centre – TCBC, Institute of Dentistry ,
University of Turku, Finland

Pekka.vallittu@utu.fi

INTRODUCTION

Large skull bone defects cause both functional and aesthetic problems to the patients. A bioactive fiber-reinforced composite (FRC) is presented to address some of the problems faced in current options for craniofacial bone reconstruction. Bioactive glass – glass fiber-reinforced composite (FRC) is potential new material for cranio-maxillo-facial reconstructions due to its non-metallic nature and bone like mechanical properties.^{1,2} Structure of the FRC implant couples osteoconductive and antimicrobial properties of bioactive glass (BG) with durable anatomically shaped FRC laminate. Osseointegration and biomineralization between FRC and bone has been demonstrated in preclinical and experimental studies.³ Synthetic, osteoconductive and antimicrobial, bioactive glass (BG) S53P4 with E-glass fibers in a new custom made composite implant for craniofacial reconstructions is presented.

EXPERIMENTAL METHODS

Retrospective series of 30 patients with craniofacial deformity, operated between 1/2007-5/2013. After the skull defect was characterized with three-dimensional computer tomography, a rapid prototype model of the skull was made from polyamide with a selective laser sintering method. This model was then used to manufacture a customized implant. The implant material consisted of a supporting fiber-reinforced framework, porous inner layers and bioactive glass filling. The composite structure of the implant allowed the biomechanical excellence of the fiber-reinforced structure to be coupled with the properties of bioactive glass. The bioactive component in the FRC implant was bioactive glass (S53P4). Static [18F]-fluoride Positron Emission Tomography (PET) fused with Computer Tomography (CT) was acquired 10-23 months post-operatively. PET-CT images were assessed for signs of new bone formation at the region of implants. Semiquantitative standardized uptake value (SUV) was obtained from [18F]-fluoride PET to evaluate metabolic activity of bone-implant interface, and mineralization was observed from CT. Histological samples were not obtained.

RESULTS AND DISCUSSION

The aesthetic and functional outcomes of all patients were good and patients were satisfactory for reconstructions. Normal progressive wound healing was observed in 28 cases out of 30. One late plate exposure and one periprosthetic infection led to implant removal, thus resulting in 6.7 % complication rate in this series of 30 patients. Both maximal and average SUV of the implant area (VOI 1) were higher compared to the reference area (VOI ref). Mineralized bone islands around the implant were observed at time-point of two years. Reconstruction of large skull defects with the novel bioactive FRC implant is a promising solution compared to conventional materials.⁴ As signs of new bone formation, bone formation activity and mineralization islets were observed two years after skull bone defect reconstruction with bioactive FRC implant.

CONCLUSION

With the limitations and the pilot nature of this study in mind, results of this study suggest that osteoconductive properties of bioactive glass can be combined with biostable fiber-reinforced composite implant even of large size, though bone bridging of such large defects is relatively slow.

INTRODUCTION

Bioglass and other silicate bioactive glasses are usually produced by casting, as bulk material with plate shapes or as powder. Applications such as middle ear prostheses or synthetic grafts are fulfilled with these material forms^{1,2}. However, extensive research has been accomplished during last years to increase the bioglass practical applications, using it as part of composites, or modifying the geometrical architecture. In this sense, a number of laser assisted techniques has been applied to face this challenge, also aiming the preservation of the bioactivity after the process and preferably being fast or economically feasible.

Bioglass-derived coatings into metallic implants were deposited by laser cladding to combine the metal mechanical properties with the bioglass superior osteoconductivity³. In addition, the three dimensional variant of the technique was employed to create free-form layered implants for low load craniofacial applications; neither moulds nor additional processing steps are required⁴. Moreover, rapid prototyping based on laser cladding allows to selectively introduce additional chemical species with antiresorptive, angiogenic or antibacterial capabilities.

On the other side, the nano-scale geometrical architecture plays an important role in the performance of scaffolds for tissue engineering. Nanofibrous structures with controlled architecture have excellent potential to mimic natural extracellular matrix and to be used as scaffolds for tissue growth. Another laser assisted process, the laser spinning technique, is the technique exclusively capable to produce nanofibers from 45S5@ BG^{5,6}

EXPERIMENTAL METHODS

Laser radiation with wavelengths in the near and mid-infrared spectra ($\lambda=1064$ nm; $\lambda=10600$ nm) is employed to irradiate bioglass microparticles. For the production of coatings on metallic surfaces, low absorbance near-infrared radiation can be used to heat up the interface layer over the transition temperature. Rapid prototyping based on laser cladding requires a high absorbance wavelength. The bioactive glass is melted within the molten pool, and the sequential substrate movement generates a layered three dimensional sample from a computer model, which resembles a specific geometry of the cranial bone.

Laser Spinning is a new technique for the production of very long amorphous bioceramic nanofibers. It employs a laser to melt a small plate of bulk bioglass while a high pressure gas jet drags it. Thus, the molten material forms glass fibers as result of its viscous elongation by

the drag force and rapid cooling by the convective heat transfer promoted by the gas jet.

RESULTS AND DISCUSSION

Laser cladding processing of bioglass produced full density coatings and three-dimensional samples (Fig.1). No species volatilization is produced and chemical composition of bioactive glass is maintained after the process. Processed samples show ion release profiles in Tris buffer equivalent to these produced by the precursor bioactive glasses; direct seeding of pre-osteoblastic cells reveal healthy morphologies.

SEM and TEM analysis show that the nanofibers obtained by laser spinning have a high length to diameter ratio. The electron diffraction patterns reveal the preservation of precursor glasses structure. EDS mapping performed by STEM shows that the elements are uniformly distributed along the fibers.

Fig.1 Implant made from BG particles by RP based on laser cladding.

CONCLUSION

The laser cladding based techniques allow to transform bioglass particles into sound coatings and 3D implants for low loading applications, without losing the bioactive behaviour. Laser Spinning allows to produce large quantities of nanofibers with lengths up to several centimetres, made with specific bioglass compositions. The precursor bioglass composition and structure was preserved after processing.

Cell behaviour affected by properties of electrospun nanofibers

Yan Wei, Wentao liu, Xuehui Zhang, Xuliang Deng*

Department of Geriatric Dentistry, School and Hospital of Stomatology, Peking University, China,

kqdengxuliang@bjmu.edu.cn

INTRODUCTION

Cell–biomaterial interactions have been shown to exert a considerable influence on the function and differentiation of mesenchymal stem cells (MSCs).^{1,2} Nanofibers, universally accepted as niche-biomimetic scaffolds in bone regeneration, have also been found to enhance the proliferation and osteogenic differentiation of MSCs.^{3,4} Although many reports have described the phenotypic and genotypic phenomena that occur during the nanofibrous scaffold-mediated osteogenic differentiation of MSCs, the biological mechanisms underlying the osteogenic behavior of MSCs in response to nanotopography have not been clearly elucidated.

EXPERIMENTAL METHODS

Temporal changes in the osteogenic behavior and dynamic global gene expression patterns of hBMSCs were assessed during their culture on random and aligned electrospun poly-L-lactide (PLLA) nanofibers without an osteogenic supplement (OS). Osteogenic differentiation was examined by real-time quantitative PCR (RT-qPCR) and global microarray analysis at 4, 7, 14, and 21 days of culture. In-depth pathway analysis was employed to explore the possible mechanism triggered by nanofibrous topography.

RESULTS AND DISCUSSION

Figure 1: SEM images and Immunofluorescence staining of hBMSCs after 1 day of culture on (a,d) flat polymer films, (b,e) random nanofibers, and (c,f) aligned nanofibers. Cell area (g) and roundness (h) of hBMSCs.

Figure 2: RT-qPCR analysis of gene expression in cells seeded on random and aligned nanofibers and flat polymer films with or without OS.

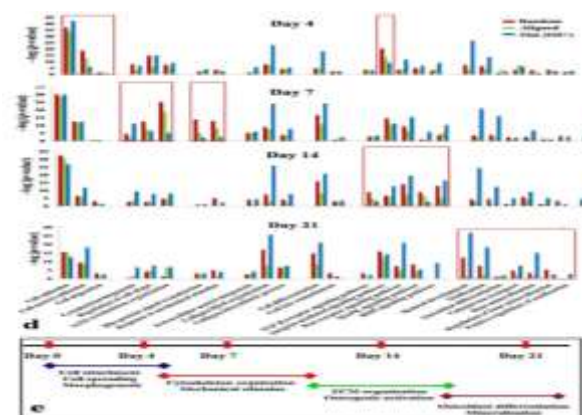

Figure 3: Gene ontology analysis and graphical summary of the osteogenic differentiation of hBMSCs triggered by random nanofibers.

The hBMSCs on random nanofibers exhibited a highly branched morphology with round nuclei, and those on aligned nanofibers displayed a polarized morphology with oval nuclei along the fiber directions. RT-PCR analysis of osteogenic marker genes and ALP activity assays demonstrated that hBMSCs cultured on random nanofibers showed enhanced osteogenic-specific fate compared with those on aligned nanofibers. Microarray analysis demonstrated a similar temporal change in gene expression patterns between hBMSCs cultured on random nanofibers and those induced with OS. However, the extent of osteogenic differentiation on the fibrous scaffold was much lower than that driven by chemical OS. In-depth pathway analysis revealed that focal adhesion kinase, TGF- β , Wnt and MAPK pathways were involved in the activation of osteogenic differentiation in hBMSCs on random nanofibers.

CONCLUSION

The findings suggested that a lower extent but similar rhythm of dynamic cellular behavior was induced on random nanofibers when compared with the OS condition, and that mechanotransduction could trigger nonspecific and multilevel responses in hBMSCs. This study provides insight into the regulation of osteogenesis directed by substratum surfaces.

Two-photon polymerization as a high-resolution tool to control surface structure of polymeric biomaterials at micro- and nanoscale

David Barata¹, Paulo Dias¹, Clemens A. van Blitterswijk^{1,2}, and Pamela Habibovic^{1,2*}

¹Department of Tissue Regeneration, University of Twente, Enschede, the Netherlands

²MERLN Institute, Maastricht University, Maastricht, the Netherlands, *p.habibovic@utwente.nl

INTRODUCTION

Besides soluble factors, genetic background and cell-to-cell interactions, the physical cell culture environment has been shown to be determinant for cell fate and consequent tissue formation. For skeletal tissue regeneration, tridimensional macroscale scaffolds, often containing pores, provide essential functional compartments, allowing cell growth, differentiation and tissue infiltration¹. However, the surface topography features at micro- and nanoscale have also been shown to play an important role in cell proliferation and differentiation^{2,3}. Two-photon polymerization (2PP) is a unique technique for rapid prototyping of surface features at nano and microscale with high resolution. In this study, we have employed 2PP to design surface of a number of materials, exploring the effect of multi-scale physical cues on cell behaviour.

EXPERIMENTAL METHODS

A commercial setup for 2PP (Nanoscribe GmbH) was used for fabrication of master structures (Figure 1A). A polydimethylsiloxane negative mould was then created and replicas were manufactured in different polymeric materials by using thermal embossing (Figure 1B). In this manner, it was possible to create identical surface features, while varying chemistry of the biomaterial. MG-63 osteosarcoma cells were cultured on selected surfaces for 72h. Image analysis of cell morphology was performed after fluorescent staining for nuclei and actin. All experiments were performed in triplicate.

Figure 1 – Schematic showing structure fabrication by 2PP (A) and SEM image of replicated structures (B).

RESULTS AND DISCUSSION

Fluorescent staining for nuclei and cytoplasm allow the identification of cell morphology upon seeding and attachment on different surfaces. Initial analysis of the fluorescent microscopy images showed evident cell shape changes upon culture on surfaces with distinct micro- and nano features (Figure 2).

Figure 2 – Cell morphology on flat (A) and rails/dashed (B) surface. Fluorescent microscopy of nuclei (blue) and cytoskeleton (red) is shown.

On flat substrates, cells spread randomly, as opposed to substrates with micro and/or nanostructured features. For example, as is shown in Figure 2 – B2, cells tend to extend in the direction of larger, microscale features, whereas nanostructures in the opposite direction seem to be responsible for “bridging” the area between the microfeatures. Moreover, cell shape on flat surfaces presented lower eccentricity and apparent larger cell area.

We are currently performing a more systematic analysis to quantify critical parameters of cell shape, which have previously been shown to be predictive of cell fate².

CONCLUSION

Here we demonstrate the potential of two-photon polymerization as a versatile tool to provide surface of polymeric biomaterials with highly controlled topographical features at micro- and nanoscale. Since this technique is a relatively slow and thus expensive way for directly “write” the features on large area, we have used it to develop master moulds which can subsequently repeatedly be used for thermal embossing of various materials.

Facile Photochemistry Enables Protein and Cell Micropatterning in Open and Closed Polymer Systems

Esben Kjær Unmack Larsen, Morten Bo Mikkelsen and Niels B. Larsen*

¹Department of Micro- and Nanotechnology, DTU Nanotech, Technical University of Denmark, Denmark,
niels.b.larsen@nanotech.dtu.dk

INTRODUCTION

Micropatterning of proteins and cells on polymer surfaces are of great utility for cell analysis as well as advanced cell culture¹. The technology challenge is two-fold in creating a background coating exhibiting low adsorption of cell adhesive proteins to minimize non-specific cell adsorption and attachment of functional cell adhesive proteins with high positional accuracy at the intended surface areas. Photochemistry is an attractive base technology as patterning may be performed with sub-cellular resolution and the process can be performed in both open and closed transparent (micro-)systems.

EXPERIMENTAL METHODS

Base coatings resulted from covalent coupling and polymerization of poly(ethylene glycol)-diacrylate (PEGDA, 5 kDa) by UV-illumination (365 nm) of an aqueous solution of PEGDA (5 mg/mL) and the photoinitiator 4-benzoyl benzylamine hydrochloride (Bz, 1 mg/mL) applied to polystyrene or polyethylene polymer surfaces. Aqueous fibronectin (FN, 100 µg/mL) and Bz (1 mg/mL) or fluorescently labeled albumin (BSA, 100 µg/mL) and Bz (100 µg/mL) was applied to the resulting PEG-coated surfaces and coupling proceeded using patterned UV light (365 nm) on a home-built projection lithography system³. Surfaces with micropatterned fibronectin as well as uncoated (negative control) or fully coated (positive control) with fibronectin were employed for in vitro cell culture experiments using HT-29 adenocarcinoma cells in 1% human serum. Cells were cultured for 16 hours at 37 deg. C (5% CO₂) before washing off weakly attached cells by PBS and visualizing the remaining cells with phase contrast microscopy.

RESULTS AND DISCUSSION

Covalent attachment of an ultrathin (<5 nm) layer of the protein non-adhesive PEG coating was verified by x-ray photoelectron spectroscopy (data not shown). The spatial resolution of the method in closed microsystems was explored using fluorescently labeled albumin inside a 70 µm high polyethylene microchannel (Figure 1), showing defined lines-and-spaces of <10 µm width and very little non-specific adsorption on the PEG coating.

Figure 1. Micropatterned fluorescently labeled albumin on a low-binding coating of PEG.

Cell cultured on the surfaces with photopatterned fibronectin showed markedly higher adhesion on the fibronectin than on the surrounding PEG coating (Figure 2). This effect was most pronounced at low added serum concentrations, as culture in 10% added serum resulted in substantially higher non-specific cell adsorption for longer culture times (data not shown)

Figure 2. HT-29 cells templated on fibronectin (FN) photopatterned on a low-binding coating of PEG.

Our results shows that polymer surfaces can be functionalized with protein and cell adhesive or non-adhesive coatings using simple photochemical processing steps under chemically gentle conditions in aqueous medium. The method can be applied to a variety of protein types including antibodies and enzymes, as demonstrated in a previous publication³, with many possible applications in advanced cell culture and analysis in open or closed microsystems.

CONCLUSION

The presented facile method can introduce both low protein adsorbing base layers as well as the micropatterned bioactive protein coating using commercially available coupling chemistry in single process steps applicable to a multitude of polymer materials.

3D Plotting of biopolymer-based hollow and core/shell structures

Ashwini Rahul Akkineni¹, Yongxiang Luo¹, Tilman Ahlfeld¹, Anja Lode¹, Michael Gelinsky^{1*}

¹Centre for Translational Bone, Joint and Soft Tissue Research, Technische Universität Dresden, Dresden, Germany, michael.gelinsky@tu-dresden.de

INTRODUCTION

The application of rapid prototyping techniques for scaffold production provides potential solutions for repair and regeneration of defects associated with various tissues. Among other rapid prototyping techniques, 3D plotting (3DPI) is a fast, reliable and versatile method for processing of pasty materials into porous scaffolds using dispensing units. Using multiple dispensing channels, scaffolds consisting of more than one material can be processed. Scaffold preparation can be accomplished in principal at mild conditions allowing *in situ* colonisation with living cells during the fabrication process itself or plotting of delicate substances like growth factors. We have recently presented a method for 3DPI of hollow strands and 3D scaffolds thereof, consisting of highly concentrated alginate pastes¹. As advancement, we now have developed the processing of core/shell strands, consisting of two different biomaterials.

EXPERIMENTAL METHODS

3DPI was performed using a three channel BioScaffolder™ from GeSiM (Grosserkmannsdorf, Germany). As plotting pastes, several biopolymers and blends consisting of alginate, chitosan, gellan gum, collagen and gelatine as well as a pasty calcium phosphate bone cement² (InnoTERE, Radebeul, Germany) were applied. Conventional plotting of pure components or mixtures of the respective materials acts as control. For generation of hollow and core/shell strands, respectively, a self-made core/shell nozzle was used. Morphology of the strands and the respective 3D scaffolds were characterised microscopically and mechanical properties determined with a Zwick testing machine. Release experiments were carried out after loading of the respective scaffolds with BSA as a model protein during plotting.

RESULTS AND DISCUSSION

Manufacturing of hollow alginate strands and 3D scaffolds thereof could be realised with highly concentrated alginate pastes (16.7 wt.-%). After plotting in air, the alginate was cross-linked in an aqueous 0.5 M CaCl₂ solution, leading to stable structures with open lumina (Fig. 1). For plotting of hollow strands, the core-part of the core/shell nozzle was kept empty and only one of the three channels of the plotter was used.

By connecting the core-part of the nozzle with the second channel, the inner lumen of a hollow strand could be simultaneously filled with another pasty material; such core/shell strands could be used to manufacture 3D scaffolds (Fig. 2 shows an example, again consisting of alginate). 3D scaffolds consisting of core/shell strands have been manufactured from several material combinations (chitosan/alginate, gellan gum/alginate, gelatine/alginate and chitosan/CaP cement) and were char-

acterised concerning their structural and mechanical properties, as well as BSA release (used as model drug).

Fig. 1: SEM image of a 3D plotted scaffold, consisting of alginate hollow strands (scale bar: 200 µm)

Fig. 2: 3D scaffold made of alginate-based core/shell strands; core part coloured with blue ink

Stiffness as well as porosity of novel core/shell scaffolds differed clearly from that of scaffolds, fabricated from both single components and homogeneous mixtures of the two materials. Loading of the core and shell part of these scaffolds with BSA leads to different release behaviour which facilitates the adjustment to the biological needs and opens up the possibility towards dual release of two different drugs from one scaffold.

CONCLUSION

3D plotting of hollow and core/shell strands provides a novel options to tailor the properties of 3D scaffolds and to create solutions for complex requirements. Mild processing conditions allow incorporation of sensitive substances like BSA during scaffold manufacturing.

Magnetic PCL - based nanocomposites for soft/hard tissue regeneration

Ugo D'Amora^{1*}, Teresa. Russo¹, Roberto De Santis¹, Antonio Gloria¹, Monica Sandri², Anna Tampieri², L. Ambrosio¹

^{1*} Institute of Polymers, Composites and Biomaterials - National Research Council of Italy ugo.damora@unina.it

² Institute of Science and Technology for Ceramics - National Research Council of Italy

INTRODUCTION

Over the past years, great attention has been focused on polymer-based materials, as 3D scaffolds or injectable formulations, for the repair/regeneration of damaged tissue, benefiting from a multi-disciplinary approach.

The basic principles of magnetism and magnetic materials have been widely used in many modern medical applications (i.e. drug and gene delivery, hyperthermia treatment of tumors...). The possibility to extend these concepts to tissue engineering has opened an exciting wide research area of interest. In designing 3D magnetic scaffolds or injectable hydrogel-based nanocomposites with magnetic properties, the rationale should be summarized in the possibility to obtain structures that can be manipulated by means of magnetic force gradients in order to attract bioaggregates (i.e. vascular endothelial growth factors, VEGF) stimulating angiogenesis and bone regeneration. Furthermore, they can also be employed as hyperthermia agents able to deliver thermal energy to targeted bodies.¹

EXPERIMENTAL METHODS

In the field of hard tissue engineering, rapid prototyping technologies allow to obtain structures characterized by a precise control of its internal architecture (i.e. optimal size, geometry and spatial distribution of pores and interconnectivity).

Fully biodegradable and magnetic nanocomposite poly(ϵ -caprolactone)-based (PCL) scaffolds were designed layer-by-layer through "3D fiber deposition" technique, by alternatively plotting fibers along selected lay-down patterns. The performances of the designed scaffolds were assessed by means of experimental/theoretical *in vitro* investigations. In particular, morphological studies were performed through Micro-CT and SEM. Micro-, Macro- and Nano-mechanical analyses were carried out through compression, tensile and nanoindentation tests. Magnetic analysis was performed in order to assess the superparamagnetic behavior of these materials. Human mesenchymal stem cells were seeded onto the scaffolds in order to qualitatively study cell adhesion and spreading through confocal laser scanning microscopy. Cell viability/proliferation was assessed by using Alamar Blue assay, whilst cell differentiation was evaluated by the measurement of ALP activity.

In the field of soft tissue regeneration, different magnetic sodium alginate-based formulations were designed. Small amplitude oscillatory shear tests were carried out on the materials, in order to assess their viscoelastic properties. The dynamic moduli G' and G'' were evaluated in the investigated frequency range. The flow behaviour and functional injectability of the

proposed materials were also assessed through steady shear measurements and injectability tests.

RESULTS AND DISCUSSION

3D Magnetic scaffolds

Morphological analyses highlighted that 3D fiber deposition is a powerful tool to manufacture morphologically-controlled scaffolds.

Results from compression tests were consistent with FEM simulations highlighting a stress-strain curve which is similar to that of flexible foams, whilst results from tensile tests showed a ductile behaviour for both the polymeric and polymer-based fibers. In order to locally map mechanical properties, nanoindentation tests were performed showing interesting results in terms of hardness and reduced modulus. Confocal analyses have shown interesting results in terms of cell adhesion and spreading. An increase in adhered number and a more evident spreading of hMSCs have been evidenced, in comparison with results obtained from the neat PCL substrates. On the other hand, the Alamar Blue assay has provided a quantitative evaluation of cell proliferation and viability over the culture time. The results obtained in terms of percentage of Alamar Blue reduction were higher for nanocomposite scaffolds than for neat PCL.

Magnetic Hydrogels

Rheological measurements highlighted a shear thinning behaviour and mechanical spectra characterized by a crossover frequency. In particular, at low frequencies these materials show a predominant viscous character. Furthermore, injectability tests have provided load-displacement curves showing an initial linear region. After a maximum load occurred, load values sharply dropped, then fluctuating and reaching a plateau. At the end of the plateau-like region all the materials were completely injected.

CONCLUSION

3D Magnetic scaffolds should be considered as a potential alternative to bone graft substitute with attractive new performances. On the other hand, magnetic hydrogels should be employed in order to repair soft tissues.

Artificial Ligaments From Poly(Vinyl Alcohol) Hydrogel Fibers

L. Corté¹, G. Zhang¹, F. Detrez¹, S. Cantournet¹, J.S. Bach² and D.N. Ku²

¹Centre des Matériaux Pierre-Marie Fourt, Mines-ParisTech, France, laurent.corte@mines-paristech.fr

INTRODUCTION

Hydrogels can have unique biocompatibility and self-lubrication performances that are of outmost interest for tissue reconstruction¹. In particular, physically cross-linked networks of polyvinyl alcohol (PVA) form non-degradable biocompatible hydrogels, which have already shown a high potential in several soft-tissue replacement applications^{2,3}. For ligament or tendon repair, however, they are limited by insufficient tensile properties and their use is usually restricted to embedding or coating of a “dry” fibrous construct. Here, we explore the potential of spun PVA fibers that swell in water to form hydrogel fibers with a high degree of macromolecular orientation. By means of microscopic observations and mechanical experiments on both single fibers and fibrous constructs, we investigate how such anisotropic hydrogels provide new substitutes having a water content and a mechanical response close to those of native ligaments⁴.

EXPERIMENTAL METHODS

Materials

PVA monofilaments with water solubility above 90°C (Solvron®, Nitivy Ltd) were purchased in the form of 675-dtex threads composed of 15 twisted continuous fibers. Polyethylene fibers (Dyneema®, DSM) were purchased in the form of 1200-dtex threads composed of 4 braided bundles of 60 continuous fibers.

Tensile testing

Single fiber testing was performed on a Bose Electroforce apparatus immersed in water at 20°C. Local strain was measured by video extensometry. Swollen fibrous constructs were tested at 20°C in air with an Instron 5966 apparatus. Tests were repeated on at least 3 samples. Details are given in ref. 4.

RESULTS AND DISCUSSION

The studied fibers are made of PVA that is over 95% hydrolyzed, similar to other grades used for implant applications⁵. Below 90°C, these fibers swell in water to form stable insoluble hydrogel fibers containing about 40wt% of water, as illustrated by diameter measurements in Figure 1a. Microscopic observations under cross-polarized light and wide-angle X-ray scattering confirm that a strong macromolecular orientation is preserved after swelling.

Figure 1b shows the tensile response of one single hydrogel fiber after a couple of loading-unloading cycles to a maximum strain of 40%. The stiffness of these oriented fibers largely overcomes that of isotropic hydrogel films with a similar water content. Pure hydrogel constructs from those fibers exhibit a geometry, water content (~50wt%) and mechanical behavior close to those of native ligaments⁶. This is illustrated in Figure 1c for anterior cruciate ligament

(ACL) substitutes using twisted and braided constructs containing 3600 and 4500 PVA fibers, respectively.

Figure 1: a. Swelling kinetics in water of a PVA fiber; b. Stabilized tensile behavior of one PVA hydrogel fiber; c. Tensile curves of PVA hydrogel fiber constructs (blue and green) and PVA hydrogel - UHMWPE constructs (red).

Smaller diameters and a safety factor in tensile strength are easily obtained when introducing polyethylene fibers. Using a hollow-braid design as shown in Figure 1c, the mechanics of these hybrid constructs can be modeled and adjusted to reproduce the non-linear tensile response with a toe region that is preferred for ligament reconstruction.

CONCLUSION

These results show that PVA hydrogel fibers with a 50wt% water content closely reproduce the large strain and non-linear elasticity of ligament tissues. This *in vitro* mechanical validation is a strong incentive to pursue more extensive *in-vivo* evaluations.

Bioactivity of Medium Chain Length Polyhydroxyalkanoate Scaffold for Soft Tissue-Engineering Applications

Aitor Larrañaga^{1,*}, Jorge Fernández¹, Carmen Ronchel², José L. Adrio², Jose-Ramon Sarasua¹

¹Department of Mining-Metallurgy and Materials Science, Polymat, University of the Basque Country (UPV/EHU) Spain.

²NEOL BioSolutions S.A.
aitor.larranaga@ehu.es

INTRODUCTION

Polyhydroxyalkanoates (PHAs) are a group of biodegradable and biocompatible polyesters which are synthesized by several microorganisms as intracellular carbon and energy storage compounds¹. Medium chain length PHAs, that contain 6-14 carbon atoms in their backbone, have low crystallinity, low glass transition temperatures, low tensile strength and high elongation at break, making them elastomeric polymers². All these properties are highly appreciated for the regeneration of soft tissues, such as tendons or ligaments³. Incorporation of bioactive glasses to the aforementioned polymer matrices could improve their osteointegration with the bone tunnel⁴, avoiding the loosening of the graft and improving long-term survivability of the implant in tissue-engineering applications.

EXPERIMENTAL METHODS

In this work a poly(3-hydroxyoctanoate-co-3-hydroxyhexanoate) copolymer was employed as base material and fully characterized in terms of molecular weight, molecular organization, chemical structure and mechanical properties by means of gel permeation chromatography (GPC), nuclear magnetic resonance (NMR), Fourier transform infrared spectroscopy (FTIR) and tensile tests, respectively.

3-dimensional porous scaffolds were fabricated by solvent casting/particulate leaching. Bioglass 45S5 was incorporated to these scaffolds and a bioactivity study was performed by submerging the samples in simulated body fluid (SBF). The formation of a hydroxycarbonate apatite (HCA) layer was monitored by scanning electron microscopy (SEM), FTIR and X-ray diffractometry (XRD).

RESULTS AND DISCUSSION

Figure 1a shows the surface of an unloaded scaffold at the beginning of the bioactivity study. After 28 days submerged in SBF (Figure 1b) little changes were observed in the morphology of the surface and no deposits were discerned.

In Figure 1c a bioactive glass particle within the polymer matrix can be appreciated. Those samples containing 15 vol.% of bioactive glass developed a HCA layer on their surface after 7 days submerged in SBF (Figure 1d). These deposits became larger with immersion time and, at day 28 (Figure 1e and 1f) several deposits were observed, covering the surface of the scaffold.

Figure 1.- SEM micrographs of unfilled scaffold at 0 (a) and 28 days (b) and scaffold filled with 15 vol.% of bioactive glass at 0 (c), 7 (d) and 28 (e and f) days.

The formation of a crystalline HCA layer on the surface of the samples was confirmed by means of FTIR and XRD (data not shown).

CONCLUSION

Scaffolds containing 15 vol.% of bioactive glass were able to develop a HCA layer on their surface only after 3 days submerged in SBF, whereas those scaffolds filled with 5 vol.% of bioactive glass needed 28 days. It can be concluded that addition of bioactive glass is a promising strategy to confer bioactivity to the employed scaffolds thus, improving the interaction with surrounding tissues.

Bioinspired Composites: Link between Alignment Control, Platelets Content and Mechanical Properties

Laetitia Galea^{1,2*}, A. Studart³, Thomas Graule^{2,4} and Marc Bohner¹

¹*Skeletal Substitutes Group, RMS Foundation, Switzerland, ²Ceramic, TU Bergakademie Freiberg, Germany, ³Complex Materials, ETHZ, Switzerland ⁴Hochleistungskeramik, EMPA Dübendorf, Switzerland, laetitia.galea@rms-foundation.ch

INTRODUCTION

It is well known from composite technology that the higher the fraction of reinforcement phase, the stronger is the composite. This law is particularly well confirmed for long fiber composites. However, to obtain tough composites, short reinforcements are required. In this case, the strength also depends on the alignment and dispersion of the reinforcing elements. Indeed, if these parameters are insufficient, percolation occurs and the strength abruptly decreases. The strengthening effect is then limited to a given reinforcement fraction. Nature reaches very good alignment in ceramic-based composites, for example in nacre. In this case, 95vol% of ceramic does not weaken the tough structure thanks to its very high alignment. Natural materials are an inspiration source for engineers, because of outstanding combination of properties. However, we do not master nature's synthesis methods. That is why in this study, it was not attempted to mimic nature's route, but the natural structure was as much as possible imitated by the use of simple processing tools.

Solvent casting was used here to prepare composite films with aligned biodegradable ceramic platelets [1]. The fraction of reinforcement phase was increased until percolation was reached. This threshold was then increased by improving the alignment of the particles in a magnetic field [2].

THEORY

Based on the aspect ratio, s , of the reinforcing elements, the theoretical percolation limit, ϕ_p , can be calculated in function of the platelets mean angle, θ [3]:

$$\phi_p = \frac{1}{\theta \cdot s} \cdot p_c \quad (1)$$

Where p_c is a constant (0.718).

The theoretical reinforcement capacity, σ_{rel} , of a given fraction, ϕ , of a material can be estimated from its s [4]

$$\sigma_{rel} = \frac{\sigma_c}{\sigma_m} = \frac{s}{6} \cdot \phi + (1 - \phi) \quad (2)$$

with σ_{rel} the relative strength of the composite, σ_c , to the strength of the polymer matrix, σ_m .

Hence, the best performance of a composite obtained by a given method can be estimated based on the alignment degree achieved.

EXPERIMENTAL METHODS

Monetite (DCP, CaHPO₄) sub-micrometric platelets (with $s_{mean} = 15$) were produced according to [1]. Magnetization was obtained by nano iron oxide particles decoration [2]. The platelets were then mixed with a 2 wt-% chitosan solution and the slurries poured in Teflon molds. Drying was performed at 30 °C for non-magnetized samples. The magnetized samples were dried in ambient conditions in the vicinity of a magnet rotating around a vertical axis. All films were then

cured for 2h at 60 °C. Dog-bone samples were punched out of the films and tensile tested. Rocking curves were obtained by X-ray diffraction (XRD) to determine the mean platelet angle in the films, i.e. to measure the deviation from perfect alignment. Cross-sections were observed by scanning electron microscopy (SEM).

RESULTS AND DISCUSSION

As expected, the strength σ of the solvent casted (SC) composite films initially increased with increasing ceramic fraction ϕ . However, beyond a certain threshold value, σ decreased (Fig. 1, empty diamonds). In parallel, the alignment of the particles decreased (increase of mean platelet angle θ , Fig. 1, solid diamonds). Comparing θ of the different ϕ with the theoretical percolation limit θ_p confirmed that above this threshold, σ enhancement was impossible. Improving the alignment quality by the use of a magnetic field (M) (Fig. 1, solid squares) allowed increasing σ further with higher ϕ (Fig. 1, empty squares). However, percolation was still reached at much lower ϕ than in natural composites ($\phi_{nacre} = 95$ vol%, $\phi_{bone} = 50$ vol%). SEM observations bore out the differences measured by XRD.

Figure 1: Mean platelet angle θ (left axis, solid lines) and relative tensile strength σ (right axis, dotted lines) as a function of ceramic fraction ϕ .

CONCLUSIONS

Classical composite synthesis methods do not reach nature's precision and scale, limiting the reinforcement possibilities in tough composites. In order to further improve strength and toughness of synthetic and biodegradable composite materials, new synthesis methods have to be developed to better control the architecture at the sub-micrometric level.

Development and Characterization of Bilayered Scaffolds Incorporated with Gold Nanoparticles as Potential Skin Substitutes

Ömer Aktürk¹ and Dilek Keskin^{1,2}

¹Department of Engineering Sciences, Middle East Technical University, Turkey

² Center of Excellence in Biomaterials and Tissue Engineering Research Center, Turkey, e129050@metu.edu.tr

INTRODUCTION

In this study, it was aimed to fabricate nanofibrous bilayered scaffolds incorporated with gold nanoparticles (AuNPs). AuNPs were utilized to understand the effect of nanoparticles on electrospinning of collagen fibers, their effect on fiber morphology and on other characteristics of the scaffolds as a potential skin substitute. It was reported that AuNPs have antibacterial and antioxidant properties; they increase cell and protein adhesion and cell proliferation on the scaffolds¹; enhance mechanical properties and resistance against degradation². Therefore, they were thought to be promising materials in skin tissue engineering.

EXPERIMENTAL METHODS

Sericin/collagen membranes³ were combined with collagen nanofibrous matrices produced by electrospinning method to obtain bilayered collagen matrices (BLCM) with AuNPs. Bilayered scaffolds cross-linked with glutaraldehyde (GTA) were characterized with the following tests: Equilibrium degree of swelling (EDS), water vapor transmission rate (WVTR), ultimate tensile strength (UTS), elongation at break (EAB), elastic modulus (E), hydrolytic and enzymatic degradation, morphological analysis (SEM), AuNPs size determination (TEM) and cytotoxicity (MTT assay) tests.

RESULTS AND DISCUSSION

AuNPs having a very homogenous size and shape distribution were synthesized at different average sizes (10-50 nm) and AuNPs having sizes greater than 20 nm were selected to be used in scaffolds regarding the preliminary cytotoxicity tests (data not shown). AuNPs could be entrapped inside the nanofibers successfully after blending with collagen/PEO (1:2.5) electrospinning solutions (Fig. 1).

Figure 1. TEM micrographs showing AuNPs A) size (36.95 ± 4.05 nm) and shape (mostly spherical) and B) the distribution inside the collagen nanofibers. Red circles indicate the AuNPs.

Nanofibrous matrices with homogenous fiber diameter (262 ± 29 nm) and shape distribution (cylindrical) were obtained. Cross-linking treatment did not considerably change the porous structure of BLCM (Fig. 2), but increased the resistance of the scaffolds to both hydrolytic and enzymatic degradation.

Figure 2. SEM micrographs showing collagen nanofibers A) untreated and B) GTA cross-linked

The main properties of the BLCM as a potential skin substitute were summarized in Table 1. Biocompatibility tests on 3T3 fibroblasts and keratinocytes showed that BLCM incorporated with AuNPs were not cytotoxic (Fig. 3). Antibacterial tests, in vitro cell adhesion and proliferation tests are still being carried out.

Table.1. Properties of BLCM

EDS (g/g)	WVTR (g/m ² /day)	UTS (MPa)	EAB (%)	E (MPa)
3.58 ± 0.58	1358.75 ± 82.62	3.36 ± 1.29	23.37 ± 8.35	40.82 ± 14.19

Figure 3. Cytotoxicity test (MTT assay) results on 3T3 fibroblasts and keratinocytes. BLCM: The extract medium of BLCM scaffold with AuNPs. Control: The group containing no AuNPs.

CONCLUSION

Selected AuNPs were successfully incorporated into collagen nanofibrous scaffolds. AuNPs enhanced the morphology of collagen nanofibers. BLCM incorporated with AuNPs were found to be biocompatible. According to characterization tests, BLCM incorporated with AuNPs could be a promising skin substitute.

Multi-scale geometric control of mechano-transduction and cell behaviour using polymer brushes

John Connelly¹, Jenny Malmström², Duncan Sutherland³ and J. E. Gautrot¹

¹*Institute of Bioengineering, Queen Mary University London, UK, j.gautrot@qmul.ac.uk

² School of Chemical Sciences, University of Auckland, New Zealand

³ Interdisciplinary Nanoscience Center, Aarhus University, Denmark

INTRODUCTION

The fate and behaviour of stem cells is determined by their microenvironment: a combination of biochemical (e.g. extra-cellular matrix, neighbouring cells, growth factors, cytokines), and physical cues (e.g. matrix mechanical properties, geometry and topography). Cell adhesion to extra-cellular matrix (ECM) is particularly important for regulating stem cell fate decision and tissue homeostasis in physiological as well pathological scenarios. In turn, this may have important implications for the design of biomaterials and engineered platforms in the field of regenerative medicine. Our work has focused on the role of micro- to nano-scale geometrical properties of the matrix on the control of the cell microenvironment and its impact on cell fate decision. To do so, we have designed well-defined engineered platforms using a combination of micro- to nano-patterning and polymer brush chemistry.

EXPERIMENTAL METHODS

Our work has focused on the design, preparation and characterisation of polymer brushes displaying ultra-low fouling properties (e.g. poly(oligo ethylene glycol methacrylate) or zwitterionic brushes), as well as novel strategies to bio-functionalise polymer brushes. In addition, we developed photo-activated chemical method to control such chemistry, thereby affording photo-dynamic platforms. Using a combination of micro- and nano-patterning approaches, we used the polymer brush systems we developed to control the behaviour of epidermal stem cells at different length scales, from multi-cellular cluster formation to individual nascent cell adhesions and studied the impact of such geometrical cues on stem cell fate decision.

RESULTS AND DISCUSSION

At the multi-cellular level, we observed that the adhesive geometrical landscape was responsible for the correct partitioning of epidermal stem cells and differentiated cells into distinct compartments, independently from the rate of differentiation¹. This phenomenon was mediated by the adhesive landscape

but controlled by adherens and desmosomal junctions. The micro-epidermis that we generated also mimicked correctly cell partitioning in squamous cell carcinoma, hence providing a novel strategy for cell assay design.

At the single cell level, we showed that epidermal stem cell spreading and shape were important determinants of fate decision^{2,3}. When cells were allowed to spread on large (50 µm diameter) or stretched adhesive islands (small 30 µm diameter with high shape aspect ratio), they differentiated less frequently. We found that this was a direct result of the rearrangement of the cell cytoskeleton and the redistribution of the pools of F- and G-actin, via the MAL/SRF pathway.

Finally, we found that controlling adhesive patterns with sizes in the 100-3000 nm range allowed the control of cell spreading and that this correlated with reduced differentiation. We found that such nano-scale effects were not mediated by the alteration of global protein sequestration to adhesion sites, but rather by the change in diffusion dynamics of the adapter protein vinculin.

CONCLUSION

Our results show that simple geometrical control of the adhesive landscape at the micro- to nano-scale guides stem cell fate decision and we identified some of the key molecular players involved in these processes. These results are important as they can serve as a basis for the development of novel cell-based assays and tissue culture platforms for applications in regenerative medicine.

Is the presence of multinucleated giant cells within the implantation bed of natural-based biomaterials physiological? Assessment of *in vitro* and *in vivo* screening of three different porcine collagen membranes by means of multichamber three-dimensional systems

Shahram Ghanaati^{1,2}, Carlos Mota³, Mike Barbeck^{1,2}, Patrick Booms^{1,2}, Robert Sader², Clemens van Blitterswijk³, Lorenzo Moroni³, C James Kirkpatrick¹

INTRODUCTION

Currently porcine-based collagen membranes are frequently applied in oro-maxillofacial surgery. All of these membranes are claimed to be biocompatible and “ideal” for soft and bone tissue regeneration. However, little is known about the tissue response to these materials after their *in vivo* implantation. The present study was designed to analyze the tissue reaction of three different collagen materials within a multichamber three-dimensional (3D) system, which we already showed to be useful for discovering regenerative medicine therapies (1). This system allows the screening of different experimental conditions *in vivo* while reducing the animal number with comparable results to single material implantation (2,3).

EXPERIMENTAL METHODS

Rapid prototyping (1) was used to generate a 3D 3x3 multichamber (1,5 x 1,5 mm) made by 300PEOT55PBT45. Each device row was filled with one collagen material. Plain devices served as controls. In a parallel study, the same collagen membranes incubated with human monocytes were implanted into SCID-mice. Histological analysis and established histomorphometrical methodologies were applied after early and late points, i.e. from 10 to 60 days.

RESULTS AND DISCUSSION

In mice the devices were intact without any visible material breakdown. Three different cellular reactions to the materials were distinguished and differed in their inflammatory cell pattern, i.e.

mononuclear vs. multinucleated giant cell reaction and *in vivo* vascularization. *In vitro* cell-based experiments were performed within the device comparable to those in standard well-plates. Human monocytes were involved in material degradation and also enhanced implantation bed vascularization. The 3D multichamber system delivered comparable results to those observed with the same materials used as plain scaffolds. This system permits *in vitro* and *in vivo* investigations as well as characterization of material-specific inflammatory responses. This innovation could serve as a platform to help keep essential *in vivo* experiments to an ethically acceptable minimum.

CONCLUSION

It has to be questioned to what extent the observation of multinucleated giant cells within the implantation bed of natural based collagen membranes can be considered as a physiological reaction. Multinucleated giant cells are known to be key markers of the foreign body reaction.

INTRODUCTION

Bioactive glass and hydroxyapatite are ceramic materials well known for their osteogenic bioactive properties¹. Bone-repair commercial products use these bioceramics with micrometer particle size and completely amorphous structure. Nowadays advances in nanomaterial synthesis, offer the possibility of preparing bioceramics with controlled nanometric particle size and nanostructure. However, the effect of the different nano-scale properties on the bioactive response of the nanobioceramics has been less studied¹. In this work, hydroxyapatite (n-HA), bioactive glass (n-BG), nanoporous bioactive glass (MBG) and nanoporous bioactive glass nanoparticles (n-MBG) were synthesized and their bioactivity were evaluated in simulated body fluid (SBF) and by osteogenic differentiation of stem cells.

EXPERIMENTAL METHODS

n-HA, n-BG, MBG and n-MBG particles were synthesized by using sol-gel based methods^{1,2}. MBG was prepared by combining evaporation induced self-assembly (EISA) technique with sol-gel method. Nanostructure and particle size of bioceramics were characterized by X-ray diffraction (DRX), high-resolution transmission electron microscopy (HRTEM), and Attenuated Total Internal Reflectance Infrared Spectroscopy (ATR-FTIR). Total specific surface area of bioceramics was determined by nitrogen sorptometry.

The ability of the biomaterials to induce the formation of bone-like apatite was evaluated in SBF. Apatitic phase was analysed by scanning electron microscopy (SEM) coupled with X-ray energy dispersive analysis (EDX) and XRD. Osteogenic differentiation properties were studied by culturing the bioceramics with stem cells isolated from dental pulp (DPSCs). Osteogenic differentiation was assessed through early osteogenic marks such as alkaline phosphatase (ALP) enzymatic activity, and Runx2 and Osx gene expression.

RESULTS AND DISCUSSION

The particle size of the nanobioceramics were the following: n-HA~40 nm, n-BG~70 nm, MBG~20 μ m, n-MBG~100 nm. XRD and HRTEM analyses confirmed that MBG and n-MBG present an internal nanostructure constituted of highly ordered porous of 4 nm in diameter. The specific surface area of n-HA, n-BG, MBG, and n-MBG were 67 m²/g, 77 m²/g, 400 m²/g, and 440 m²/g, respectively.

Bioactive glass ceramics promotes a faster formation of apatite in SBF than n-HA, which is attributed to the more amorphous and reactive nature of the bioactive glasses. Particularly, n-BG and n-MBG particles accelerate the apatite mineralization process at short time of immersion in SBF (12 h). These nanosized particles also produce a higher activity of ALP (Fig. 1) as well as a high-level expression of osteogenic differentiation genes (Runx2) when cultured in presence of DPSCs.

Fig. 1 Qualitative ALP activity (staining) of DPSCs cultured in the presence of the nanobioceramics.

Although micro-sized MBG presented a high internal surface area due to its nanoporous structure, external surface area of the nanoparticles seem to be a more decisive factor on their bioactivity properties. Higher activity of n-BG and n-MBG particles can be attributed to their more rapid dissolution rate as consequence of its high external surface area exposed to the physiological medium, which is determined by the nanometric dimensions of the particle.

CONCLUSION

Nanoscale structure of bioceramics affects their bioactivity and osteogenic differentiation properties. It is concluded that nanometric particle size is a more decisive property than internal nanostructure on the bioactive response of the bioceramics with nanoscale dimensions.

The Modelling of Self-Inflating Tissue Expanders

X. Min and J. T Czernuska

Department of Materials, University of Oxford, United Kingdom, xue.min@materials.ox.ac.uk

INTRODUCTION

Tissue expansion is a common clinical technique that generates tissue. It was first described by Neumann in a case of ear reconstruction from traumatic amputation in 1956.[1] Swan et al. developed a novel anisotropic self-inflating poly(NVP-co-MMA) hydrogel expander by hot-pressing[2]. This type of expander can absorb body fluid and swell in only one direction. This present study indicates the possibility of making a bilateral anisotropic expanding tissue expander, which expands in two directions. It is therefore essential to have a discussion on the necessity of bilateral expanders before the experimental research. In order to compare the discrepancy of tissue generating capacity given by different swelling pattern, a series of expander models in syndactyly has been designed and calculated.

EXPERIMENTAL METHODS

In the case of simple syndactyly, a section of fused fingers is selected and simplified into two cylinders bound with a layer of tissue. The expander models can therefore be placed between the tissue and phalanxes. The core idea in this study is to compute the final size of expander for generating the tissue required by a reconstructive surgery. The area of required tissue equals the area of tissue in the normal state minus the area of tissue in the syndactyly state. Therefore we obtain and compare the size of different swollen expanders.

RESULTS AND DISCUSSION

Three kinds of expanders have been studied: isotropic (Figure 2(a)), unidirectional (Figure 2(b)) and bilateral (Figure 2(c)). For the purposes of calculation, several conditions have been examined.

Firstly, for a certain expander, its insertion site can influence the final results. The expander can be placed in the middle, on the top or on both sides of phalanxes (shown in Figure 1).

Figure 1: Location of insertion

Second is the insertion pattern. The expanders can be placed as a single expander or a series of discrete expanders, as shown in Figure 1(b) and Figure 2(c) respectively. Discretely inserted expanders are designed to be spheres or cylinders, as shown in Figure 2.

Figure 2: Discrete insertion of three types of expanders

Lastly, the coherence of tissue is considered. The area of tissue obtained by expansion can be affected due to the contact between tissue and expanders. For the sake of modelling, we take these two extreme cases into account: non-sticky tissue (Figure 3(a)) and complete adhesive tissue mode (Figure 3(b)). As a result, we have generated a possible range that should bound the real cases.

Figure 3: Contact modes between tissue and expander

According to the computational results of models that have included the above assumptions and situations, we obtained: (1) bilateral expander requires a smaller radius to generate the same amount of tissue as an isotropic expander; (2) uniaxial expander could have smaller sizes than bilateral expander, but only with a relatively high ratio of its height to radius. Such a sacrifice of connection area with tissue could result in tissue necrosis in practice; (3) insertion on both sides (top and bottom as in Figure 1(c)) is the most efficient way for a surgery.

CONCLUSION

These results should provide the surgeon a better insertion pattern for syndactyly. Bilateral self-inflating expanders could have advantages over other self-inflating expanders in syndactyly. Therefore, it is necessary to have a further study on the bilateral self-inflating tissue expanders.

INTRODUCTION

Nowadays, the treatment with conventional drugs is shifting towards therapeutic proteins that are exquisite specific and selective in executing diverse biofunctions. Glycosaminoglycans (GAGs) are natural partners of proteins in the extra cellular matrix: they stabilise and/or protect proteins from denaturation and enzymatic degradation; play a role in proteins storage or mediate their binding to specific receptors. Inspired by the native environment of proteins, we propose the use of sulfated (GAG) diblock PEG copolymers (GAG-*b*-PEG) for the encapsulation of proteins into nanosized interpolyelectrolyte complexes (IPECs).

Figure 1. Complexation process between GAG-*b*-PEG and (PLL).

EXPERIMENTAL METHODS

The block copolymers were synthesised following previously described procedure for hyaluronan-*b*-PEG.¹ NMR and GPC were used to confirm the structure and molecular weight of the final products. IPECs were formed by adding a solution of poly-L-lysine (PLL) or FGF-2 in phosphate buffer pH 7.4 I=10 mM to the solution of GAG-*b*-PEG under vigorous stirring. IPECs were characterised by dynamic light scattering, nanoparticle tracking analysis and electron microscopy.

RESULTS AND DISCUSSION

Oxime click reaction was used for the synthesis of diblock copolymers of polyethylene glycol (PEG) and glycosaminoglycans (GAG) with different molecular weight (Mw) and degree of sulfation (DS) (Table 1). We have tested several ratios between the PLL and the obtained copolymers. The characteristic of the PLL/GAG-*b*-PEG complexes at minimal zeta potential and low PDI are included in Table 1. As can be seen, IPECs with tunable size at the nanometric scale and narrow distribution were obtained.

Table 1. Properties of GAG-*b*-PEG block and IPECs prepared from them with PLL

GAG _{nk} - <i>b</i> -PEG ^a	GAG 10 ⁻³ Mn, [g/mol] (Mw/Mn)	DS	R _h [nm]	PDI	ζ potential
CS _{2.7k} - <i>b</i> -PEG	2.7 (1.20)	0.7	208	0.49	0.4
CS _{14k} - <i>b</i> -PEG	14 (1.39)	0.9	40±1	0.05±0.04	-1.2
CS _{24k} - <i>b</i> -PEG	24 (1.33)	0.9	94±8	0.08±0.02	0.3
HAS _{12k} - <i>b</i> -PEG	12 (1.80)	1.7	22±1	0.09±0.02	-0.1
HAS _{36k} - <i>b</i> -PEG	36 (1.50)	3.0	25±1	0.16±0.05	0.4

^a subindex denotes the molecular weight of GAG block (kDa), PEG Mw is 5 kDa; CS- Chondroitin sulphate, HAS-sulphated hyaluronic acid.

Moreover, the size can be controlled by DS: highly sulfated GAGs form the smallest complexes that are stable to at least 500 mM ionic strength. Formation of IPECs was also achieved with a human protein FGF-2 with 98±7 nm radius and PDI 0.22±0.02 and CS_{12k}-*b*-PEG.

Figure 2. STEM images of the IPECs from PLL and CS_{12k}-*b*-PEG

CONCLUSION

The ability of sulphated GAG-*b*-PEG copolymers to carry positively charged proteins has been demonstrated by their assembly with poly-L-lysine as a model protein. The formed IPECs have neutral charge, nanometric size and stability at physiological ionic strength - properties that contribute to prolonged blood circulation times and thus, more effective delivery to the targeted site. Moreover, the complexation with basic fibroblast growth factor (FGF-2) demonstrates the feasibility of these copolymers for proteins encapsulation. These properties together with the possibility for tunable size emphasise the enormous potential of sulfated GAG-*b*-PEG copolymers for the engineering of delivery systems for positively charged proteins.

INTRODUCTION

Low back pain related with intervertebral disc (IVD) degeneration is a major cause of lack to work in industrialized countries. Inflammation has been correlated with disc degeneration, although its role in discogenic pain remains controversial.¹ Here we purpose first to establish a pro-inflammatory disc organ culture model. Our goal is to evaluate a new anti-inflammatory therapy based on Chitosan (Ch)/Poly-(γ -glutamic acid) (γ -PGA) nanoparticles (NPs) with an anti-inflammatory drug (Diclofenac, Df) incorporated, previously developed by us.² Previous studies have shown that this delivery system was efficient in reducing macrophage activation in vitro.

EXPERIMENTAL METHODS

Bovine caudal disc punches cultures (DMEM with 5% FBS and 5 mM glucose, 400 mOsm and 6% CO₂ during 5 days) were needle-punctured and stimulated with: Lipopolysaccharide (LPS) 10 μ g/mL, or with Interleukin-1 β (IL-1 β), 10 and 100 ng/mL, for 48h. The effect of the pro-inflammatory stimulus was evaluated by gene expression of pro-inflammatory cytokines (IL-6, IL-8), metalloproteases (MMPs, MMP1 and MMP3), and extracellular matrix (ECM) proteins (collagen type II (Coll II), Aggrecan). Cell viability was analyzed by LIVE/DEAD assay while metabolic profile of the cultures was traced by Glucose/Lactic acid monitoring. As an anti-inflammatory therapy, Ch/Df/ γ -PGA NPs prepared by co-acervation method², were added to disc cultures 3h after pro-inflammatory stimulus. Untreated samples were used as controls. The effect of the anti-inflammatory therapy was evaluated by gene expression and by Prostaglandin E₂ (PGE₂) production.

RESULTS AND DISCUSSION

To establish a pro-inflammatory ex vivo model of IVD, LPS and IL-1 β treatments were compared. IL-1 β -treated discs showed a statistically significant up-regulation of the pro-inflammatory cytokines (IL-6 and IL-8), MMPs expression (MMP1 and MMP3), while ECM proteins (Coll II and Aggrecan) were significantly down-regulated (Fig.1). For all the conditions tested, cells remain viable and presented similar metabolic activity. IL-1 β stimulation was selected as the most adequate approach to study anti-inflammatory therapies for IVD. Regarding the effect of NPs as Df-delivery system in the IVD organ cultures, preliminary results showed that, IL-6 and MMP1 were down-regulated, when compared to IL-1 β stimulated groups, suggesting that this treatment not only reduces inflammation, but also can delay and/or decrease matrix proteins degradation.

Fig.1. Quantitative analysis of pro-inflammatory markers of IVD organ cultures with pro-inflammatory stimulus (LPS and IL-1 β). mRNA expression of IL-6 and IL-8 (a), MMP-1 and MMP-3 (b) and Coll II and Aggrecan (c). Levels of mRNA were normalized to GAPDH and to the control group. Results are shown as Mean \pm StDev (n=4-10). * = p<0.05; ** = p<0.025; *** = p<0.001.

PGE₂ levels were reduced in the presence of Df-NPs for both IL-1 β concentrations, indicating that, in this range of concentrations, the effect of released Df is not IL-1 β concentration-dependent. We have compared the Df-NPs injection in IVD with Df-NPs in IVD culture medium. The results indicate that injection group induces a better response (Fig.2).

Fig.2. PGE₂ concentration detected at day 8, in culture medium supernatant, in the presence and absence of pro-inflammatory stimulus (IL1 β) and anti-inflammatory treatment with Ch/Df/PGA NPs. Results are presented as Mean \pm StDev (n=2-4).

CONCLUSION

An ex vivo model of degeneration/inflammation in IVD was here established, with increased levels of pro-inflammatory cytokines and MMPs and reduced ECM protein levels. This approach is suitable for in vitro testing of regenerative or anti-inflammatory strategies of disc degeneration. Ch/Df/ γ -PGA NPs revealed to be a promisor anti-inflammatory therapy to IVD.

INTRODUCTION

Gold nanoparticles (AuNPs) are promising candidates as nanoscopically assembled materials for numerous applications due to the unique electronic and optical properties that result from their nanometer size and narrow size distribution.¹

In this study, the reducible biomimetic polymer-protected AuNPs were prepared by autoredution without the addition of any reducing agent, showing excellent colloidal stability at a high salt concentration and over a wide pH range. Label-free detection of an inflammation marker, C-reactive protein (CRP), was demonstrated by using the aggregation of the AuNPs.

EXPERIMENTAL METHODS

Poly(2-methacryloyloxyethyl phosphorylcholine)-*b*-poly(*N*-methacryloyl-(*L*)-tyrosine methylester) (PMPC-*b*-PMAT; Fig. 1) was prepared by reversible addition fragmentation chain transfer (RAFT) polymerization. For preparing AuNPs by autoredution, HAuCl₄/phosphate buffer saline (PBS) was added to the polymer aq. solution at different concentrations under vigorous stirring. NaOH aq. solution was introduced, and the reaction was allowed to proceed under vigorous stirring at 60 °C for 15 h. Characterization of AuNPs bearing PMPC-*b*-PMAT was performed by transmission electron microscopy (TEM), dynamic light scattering (DLS) analysis, thermogravimetric analysis (TGA) and UV-Vis absorption spectroscopy.

Detection of CRP with AuNPs bearing MPC block copolymers was demonstrated in pH 5.5. The AuNPs suspension was mixed with 500 µL of 2 mM CaCl₂ in 2-morpholinoethanesulfonic acid and monohydrate (MES) buffer or only MES buffer (Ca²⁺ free) in a plastic tube. Appropriate amounts of CRP/HEPES and MES buffer were then added to the tube. After all samples were mixed, the tubes were stored at room temperature and optical analyses for AuNPs were performed.

Fig. 1 Chemical structure of PMPC-*b*-PMAT

RESULTS AND DISCUSSION

To obtain PMPC-*b*-PMAT, PMPC was synthesized as a macro chain transfer agent (macro-CTA). The degree of polymerization (DP_n) of macro-CTA was adjusted to

Fig. 2 Detection of CRP by PMPC-*b*-PMAT-protected AuNPs: (A) Change in the size of AuNPs in contact with CRP for 30 min. ■: [Ca²⁺] = 1 mM, ●: [Ca²⁺] = 0 mM

98. Block copolymerization of MAT proceeded at a [MAT]/[macro-CTA] ratio of 20. Under our experimental conditions, DP_n of MAT was 6, which was lower than that of the target DP_n.

The colloidal stability of the AuNPs bearing PMPC-*b*-PMAT was excellent. Both size and the absorption band (λ_{LSPR}) from the localized surface plasmon resonance (LSPR) of AuNPs did not change with additional increments of ion strength upto ~ 3.8 M NaCl in the aqueous medium.

Fig. 2 shows the CRP-concentration dependence on the aggregate sizes formed by the AuNPs and CRP. The pH of the medium was adjusted to 5.5 to facilitate CRP-PC interaction. When Ca²⁺ was not in the medium, the size of PMPC-*b*-PMAT-protected AuNPs did not change regardless of CRP concentration. In contrast, the AuNPs formed remarkable aggregates in the presence of 1.0 mM Ca²⁺ and the size of the aggregates increased with an increase in the concentration of CRP over the range of 0 to 80 nM. The acceptable detection levels were below 20 nM.

CONCLUSION

Autoredution of aurum ions with the reducible MPC block copolymers results in the generation of various, highly dispersible AuNPs, which can be used for biomedical applications. As proof of this concept, the label-free detection of CRP as an inflammation biomarker was successfully demonstrated by using the biomimetic block copolymer-protected AuNPs.

INTRODUCTION

The development of instructive substrates with application in tissue regeneration has become the focus of intense research in the last years¹. This work reports a new system that is simultaneously bioinstructive, due to the presence of immobilized growth factors (GFs) that control biological function, and bioresponsive as it promotes the assembly into microgels using cells as attachment points. It is well established that platelets are an important source of autologous and complex mixture of GFs that can modulate cell proliferation and differentiation². Herein we propose antibody-conjugated chitosan-based microparticles (μPs) as a method to select specific GFs from platelet lysates (PLs), which will then be used to modulate cell function.

EXPERIMENTAL METHODS

Microparticles (μPs) were fabricated by spraying a chitosan solution (1.5% w/v) through an aerodynamically assisted jetting equipment (Nisco Encapsulation Units VAR J30) into a solution of NaOH (1M). μPs were functionalized with anti-human Platelet Derived Growth Factor-BB (PDGF-BB) antibody through carbodiimide (EDC) chemistry. Briefly, EDC was used to activate the carboxylic groups of the antibodies. The activated samples were mixed with the μPs with gentle rotation for 3 hours at 4°C. PLs were obtained from different platelet collections performed at Instituto Português do Sangue (Porto, Portugal). Collected samples were subject to three repeated temperature cycles (– 196 °C; 37 °C). The selection of PDGF-BB, was obtained by mixing the μPs with the PLs at 4°C for 15min. μPs were washed and resuspended with human adipose stem cells (hASCs). Morphological analysis of the constructs was done by Scanning Electron Microscopy (SEM) and confocal microscopy. In vitro studies were performed for up to 7 days to analyze cell viability and proliferation.

RESULTS AND DISCUSSION

Cells present surface receptors that recognize and bind to PDGF-BB. Thus functionalized μPs with PDGF-BB will work as binding points for cells, leading to the formation of a 3D hydrogel-like structure while simultaneously promoting cell proliferation and differentiation within the construct (Fig. 1A).³ The capture of PDGF-BB from PLs was assessed by ELISA assay on the remaining lysates solution post-incubation with the μPs. Results show a decrease in the amount of this GF in solution when compared to TFG and VEGF. This results support our hypothesis that the functionalization of the μPs was effective and that they are selective for PDGF-BB. The assembly of the microgels was followed for up to 24 hours. Controls in absence of cells or by using non-modified μPs were

used. Results show (Fig.1B) that after 90min, a 3D structure is already formed on its own. On the other hand, controls were not able to form a stable structure. Biological activity of the obtained constructs was assessed up to 7 days by alamar blue assay and DNA quantification. Results show an increase in cell proliferation and activity up to 7 days. SEM and confocal images revealed a homogeneous 3D construct with hASCs entrapped within the μPs. (Fig. 1C)

Figure 1. A) Schematic representation of the strategy. μPs modified with specific antibodies recruit GFs of interest from PLs. μPs are mixed with cells. A construct is formed through cell-particle interaction. B) Images of the assembly process at different time points. C) Confocal image of the construct after 3D in culture. Scale bar 100 μm

CONCLUSION

The present study addresses the hypothesis that the combination of μPs tailored with specific GFs and stem cells can generate bioactive microgels with tunable cell function through cell crosslinking. The obtained construct simultaneously provides support for stem cell proliferation, as well as localized and sustained presentation of factors to modulate cell function. Different formulations with a combination of GF can be used for a particular application based on the desired composition and intended cellular function. Furthermore, these instructive microgels may be used as an injectable system for non-invasive tissue engineering applications.

INTRODUCTION

The extra-cellular matrix represents a biological hierarchical nanocomposite and studies with mimetic nanomaterials have been shown these materials to have regulatory effects over stem-cell adhesion¹, migration², proliferation³, signalling⁴, genetic expression and stem cell fate⁵. Consequentially, biomaterial design has focused on the introduction of nanoscale elements that elicit directed cellular behaviour while imparting structural and mechanical advantages to induce the formation of functional tissues.

Adherent cells are complex, self-sustaining units that require extracellular matrix (ECM) anchorage to proliferate and undergo differential function. That nanoscale features can affect differential cellular behaviour through integrin-mediated cell adhesion is evident from studies with fabricated topographical features, however the mechanical properties of a cell's environment are also important factors in determining cell behaviour and ultimately, phenotype.

Thus far, many aspects of the cellular rigidity-sensing mechanism, particularly in reference to tactile cell sensing of discrete localised areas of increased or decreased rigidity are not understood. Here we discuss the roles of nanotopography and heterogeneous nanorigidity on stem-cell adhesion and differential function.

EXPERIMENTAL METHODS

Electron-beam lithography and di-block co-polymer self-assembly methods coupled with reactive ion etching were employed to fabricate nanomodified materials. Importantly, we describe a novel system driven by direct focused electron-beam patterning for the fabrication of soft (350 kPa) planar PDMS substrates, which present ordered submicron scale differential rigidity. Substrates were shown to undergo a linear increase in rigidity with E-beam dose, up to 3.5 MPa. We subsequently explored the response of human mesenchymal stem cells (MSC) isolated from bone marrow aspirates, to these materials.

RESULTS AND DISCUSSION

MSC's cultured on heterogeneous rigidity-patterned substrates were observed to colocalise focal adhesion formation to the stiffer regions, which correlated with spot stiffness (**Fig. 1**). However, focal adhesion colocalization was reduced by decreasing the spot diameter from 2 μm – 100 nm. Focal adhesions formed on regions of increased modulus were associated with an increase in paxillin recruitment, indicating a role in force-mediated focal adhesion reinforcement. Our studies suggest that cellular rigidity sensing and focal

adhesion reinforcement is initiated on discrete regions of modulated rigidity measuring $\sim 0.5 \mu\text{m}$, and that a 3x increase in elastic modulus is required to initiate differential focal adhesion on discrete regions of altered rigidity.

Fig. 1. (A) Trailing edge of an MSC cultured on patterned heterogeneous rigidity 2 μm spots. Green (paxillin). (B) Intensity profile of focal adhesion associated paxillin spanning five rigid spots.

CONCLUSION

MSC's respond to submicron scale topography and rigidity through differential focal adhesion formation. Furthermore, our studies indicate a submicron scale for a rigidity dependent contractile unit of the focal adhesion with which cells perceive discrete regions of altered rigidity. Future work will investigate the role of heterogeneous rigidity coupled with nanoscale topography in modulating the cellular phenotype and the translation of nanoscale topography to electrically conducting systems with aim to fabricating next-generation neuroelectrodes.

INTRODUCTION

It has been reported that strontium-substituted bioactive glasses (Sr-BGs) may promote osteoblast proliferation and inhibit osteoclastic activity in bone cell line studies *in vitro*¹. These observations suggest that Sr-BGs may form the basis for the development of improved bone graft substitutes, an area of growing clinical need. To further explore their potential, the aim of this study was to investigate the effect of particulate Sr-BGs on bone marrow mesenchymal stromal cells (BM-MSCs) differentiation.

EXPERIMENTAL METHODS

Three Sr-BG compositions were fabricated by a melt-quench route based on 45S5 bioactive glass, in which calcium was substituted by Sr on molar proportions of 0 (Sr0), 50 (Sr50) and 100% (Sr100). Sr-BG powders (<45 µm, particle size) were produced through milling and sieving. The glasses were characterised using X-ray diffraction (XRD) analysis and differential thermal analysis (DTA). Glass solubility was measured using a method based on ISO6872, while density was calculated and then determined using the Archimedes method. Cytotoxicity of Sr-BG dissolution products was assessed using monolayer cultures of rat BM-MSCs (n=3) exposed to 5-160 mg of glass powders placed in tissue culture inserts for 72 h. A resazurin dye based assay was then used to determine metabolic activity by measuring fluorescence emission. Finally, the osteogenic effect of Sr-BGs was studied by measuring the levels of expression of 6 genes associated with the process of osteoblastic differentiation: *Bmp2*, *Runx2*, *Alpl*, *Col1a1*, *Bglap* and *Spp1* using real-time PCR (rt-PCR). The analyses were performed on monolayer cultures of BM-MSCs (n=3) exposed to 20 mg of Sr-BG powders placed in tissue culture inserts for 1, 3, 6 and 14 d and cultured using cell culture media with and without osteogenic factors.

RESULTS AND DISCUSSION

XRD spectra confirmed that the three Sr-BG compositions were amorphous and showed no significant crystalline phases. The diffraction maximum was observed to move to smaller values of angle 2θ with increasing strontium substitution. DTA showed a decrease of glass transition temperature with strontium substitution, from 525°C for Sr0 to 479°C for Sr100. Solubility and density were observed to increase linearly with strontium substitution. These results, in line with previously published work^{2,3}, suggested an expansion of the glass network in order to accommodate the larger Sr cation, increasing glass solubility and potentially affecting their cytotoxicity and bioactivity.

Metabolic activity of cultured BM-MSCs generally decreased in the presence of up to 80 mg of all Sr-BG powders used. Sr100 exhibited the greatest metabolic inhibition, suggesting a greater cytotoxic effect associated with the increased solubility. Sr50 was the most biocompatible composition evaluated in this part of the study.

Data from rt-PCR analyses showed that the presence of Sr-BG powders stimulated the up-regulation of all osteogenic genes studied. It may be that the presence of Sr in Sr50 and Sr100 BGs resulted in the enhanced up-regulation of genes *Alpl*, *Col1a1* and *Bglap* compared with Sr0.

CONCLUSION

The incorporation of Sr in the composition of BGs resulted in detectable changes in their physical properties, due most likely to the expansion of the glass network, potentially affecting their biological properties. Sr-BG dissolution products appeared to stimulate the up-regulation of several genes associated with the osteoblastic differentiation of BM-MSCs. In conclusion, these are highly promising biomaterials for use in bone regeneration applications, including as a component of a scaffold for bone tissue engineering.

INTRODUCTION

An important aim of regenerative medicine is to design smart biomaterials to trigger specific biological responses. Subsequent testing often focuses on assessing anticipated cell behaviour such as differentiation and/or tissue formation. Although this strategy allows for assessment of specific outcomes, the global cell response to and mechanism of action of many biomaterials remains unknown. Unsupervised techniques that allow for assessment of global response may highlight a biomaterial's mechanism of action and allow for prospective material design.

There is a need for smart biomaterials as alternatives to autogenic/allogenic bone grafts. Strontium ranelate reduces vertebral and non-vertebral fractures in osteoporotic women¹. The incorporation of strontium into bioactive glasses (SrBG) has been shown to upregulate bone formation *in vitro*^{2,3}. However, how biomaterials such as BG affect the global biological response and the means by which strontium influences bone formation are largely unknown.

EXPERIMENTAL METHODS

As a model for this alternative approach to examine cell response to biomaterials, we exposed human bone marrow-derived mesenchymal stem cells (hMSC – 3 donors) to cell culture medium conditioned with BG with and without strontium (0, 10, 100 mol%). hMSC were exposed for 30 minutes, 2 hours, 4 hours, 48 hours, 5 days or 10 days. Whole genome microarray analyses were carried out using an Affymetrix ST 1.0 gene array and data analysed using functional annotation clustering and other novel, unbiased approaches. Further investigations of cell response were performed using quantitative real-time PCR, In-Cell Western blotting, high resolution Raman spectroscopy mapping, and TIRF microscopy.

RESULTS AND DISCUSSION

Rather than directly upregulating hMSC osteoblast differentiation, which functional annotation clustering noted as only a secondary effect, SrBG strongly regulated the steroid biosynthesis and mavelonate pathways (Table 1). Moreover, a novel and unbiased sparse selection (expectation maximization) algorithm analysis revealed strong regulation of: *FDFT1*, encoding squalene synthase, a key protein of the isoprenoid pathway which controls the synthesis of sterol metabolites; *TMEM147*, a transmembrane protein found in the ER that binds to cholesterol; and *PMP22*, a glycoprotein associated with lipid rafts.

Functional annotation clusters	Enrichment Scores	p-values
Sterol/steroid biosynthesis and metabolic process	10.02	2.7E-13
Protein-DNA complex/nucleosome	3.55	1.9E-05
Histone H2A/citullination	3.06	1.6E-04
Fatty acid biosynthesis	2.76	1.7E-04
Cell cycle process	2.61	7.0E-04
Mitosis / cell division	2.38	6.0E-04
Steroid biosynthesis/endoplasmic reticulum membrane	2.27	1.6E-07
Sterol transport and homeostasis	1.75	1.5E-02
Bone development/osteoblast differentiation	1.74	2.7E-03
Fatty acid biosynthetic and metabolic process	1.48	4.8E-03
DNA repair metabolic process	1.40	1.8E-02
Condensed nuclear chromosome	1.37	2.8E-02

Table 1: Functional annotation clustering of differentially expressed gene clusters in Sr100- and control-treated hMSC.

Changes in gene expression (confirmed by RT-PCR and WB) were translated to modifications at the protein level. Sr100 treatment increased cellular and membranous cholesterol content and membrane lipid raft content (Figure 1).

Figure 1: A) & B) False-colour Raman spectral maps of hMSC cultured in basal (CTL) and Sr100-conditioned medium. Areas with cholesterol-rich spectra appear red. C) Quantification of cholesterol-rich spectra. D) & E) Quantification of Filipin III (cholesterol) and cholera toxin β abundance (lipid raft content) from TIRF images.

CONCLUSION

These data highlight an unexpected potential mechanism of action for SrBG on osteoprogenitor cells via upregulation of the steroid biosynthesis and related pathways. They also show the potential for unsupervised approaches to transform materials design, particularly in bone regeneration.

Application of FIBSEM and XRM to study the occlusion of dentine tubules from a calcium sodium phosphosilicate bioactive glass (NovaMin™)

Richard Langford^{*a}, Jonathan Earl^b, and Arno Merkle^c

^a*Cavendish Laboratory, University of Cambridge, UK., rml42@cam.ac.uk*

^b*Jonathan Earl, GlaxoSmithKline Consumer Healthcare, Weybridge, UK.*

^c*Carl Zeiss X-ray Microscopy, Pleasanton, USA.*

INTRODUCTION

Bioactive glasses are reported to bond to bone or dentine by forming a carbonated hydroxyapatite layer. Here we report on the study of a calcium sodium phosphosilicate bioactive glass of the 45S5 composition, trade name NovaMin™, and sold commercially as the active ingredient in toothpaste for the treatment of dentine hypersensitivity. Here we report on the use of various modern electron and x-ray microscopy (XRM) techniques used to study both the tubule occlusion and the remineralisation of demineralised dentine.

EXPERIMENTAL METHODS

Sound human molars were ethically acquired and were prepared into dentine discs in the standard way. These were then demineralised with 5% w/w citric acid for 30 seconds to open the dentine tubules before treatment by immersion in artificial saliva containing or not the calcium sodium phosphosilicate bioactive glass for up to 2 hours.

RESULTS AND DISCUSSION

Focussed Ion Beam Scanning Electron Microscopy (FIBSEM) was used to prepare site specific cross sections and to perform slice and view for 3D chemical and structural analysis. Figure 1 shows a secondary electron image of a FIB cross-section. The occluding of the tubule by the nucleated hydroxyapatite-like material can be seen. It was found to extend down to the depth of the cross-section (20 µm). The corresponding untreated demineralised samples showed a non mineralised band at the top of the sample that was 500 nm thick with no layer formed on the surface or occluding material.

Fig. 1 – FIBSEM cross section through a NovaMin™ treated dentine sample

FIBSEM milling was also used to prepare a 30 µm square cube for x-ray tomography. The cube was cut out from the dentine substrate using the FIB and mounted onto a support pin by means of platinum

deposition within the FIBSEM. Figure 2 shows the 3D rendering of the non destructive x-ray tomography data. This data in conjunction with the FIB slice and view data has been used to quantify properties such as the volume filling of the tubules and the material mass density within the remineralised zone.

Fig. 2 – 3D rendering of nanoscale non-destructive XRM data

For high resolution analysis the FIB was used to prepare site specific TEM lamellae through the treated layers and the occluded material. High resolution nanoelectron diffraction and chemical analysis (EDS and EELS) showed that the material formed on the surface and in the tubules was hydroxyapatite-like. A detailed study of the remineralisation of the demineralised zone, the interface between the formed hydroxyapatite like material on the surface and the dentin matrix and the material nucleated onto and around the bioactive glass itself will be presented.

Fig. 3 – Bright field image of a FIB prepared lamella through a dentinal tubule showing the occluding material (insert shows a SE image of the whole lamella showing the material formed at the surface).

CONCLUSION

Various electron microscopy techniques have shown that the material of the layer occluding the tubules is hydroxyapatite-like and that it also results in remineralisation of demineralised dentine.

Osteoblast-like cell reactions to soluble silicate ions released from bioactive glass and siloxane-containing vaterite

obata.akiko@nitech.ac.jp

INTRODUCTION

Inorganic ions released from bioactive glasses have been reported to enhance several functions, such as proliferation, differentiation and mineralization, of osteogenic cells.¹ Soluble silica and calcium ions released from 45S5 type bioactive glass (BG) show the up-regulation effects on osteoblast activities. Many reports demonstrated that the two ions released from other bioceramics and glasses showed the similar effects on osteoblast activities. There are, however, differences in the Si ion concentration which is needed for the enhancement or inhibition of the cell functions between the reports. In addition, it was unclear whether the ions show the same stimulation effects on different types of osteoblast-like cells and the effects depend on ionic state of the ions.

Siloxane-containing vaterite (SiV) powders have been developed using aminopropyltriethoxysilane (APTES) as a siloxane source in our previous work.² SiV and poly(lactic acid) composites were prepared for the use in bone tissue regeneration. Mouse osteoblast-like cell (MC3T3-E1) showed a higher proliferation and differentiation abilities on the composite in comparison with a composite prepared with conventional vaterite.³ The soluble silica ions released from the composites were expected to stimulate the cell functions.

The aim of the present work is to estimate the effects of soluble silica ions released from BG or SiV on two different types of osteoblast-like cell functions.

EXPERIMENTAL METHODS

SiV powders were prepared with the carbonation method reported previously.² 150 g of calcium hydroxide, 60 ml of APTES and 2 L of methanol were mixed with the addition of CO₂ gas for 75 min at a rate of 120 L/h, and then dried at 110 °C, resulting in the formation of SiV powders (≈1.5 μm in diameter). The silicon concentration in the resulting powder was found to be 2 wt% by X-ray fluorescence analysis.

BG was prepared by a melt-quenching method. SiO₂, CaHPO₄·2H₂O, CaCO₃ and Na₂CO₃ powders were mixed and then melted at 1400 °C for 1 h. The obtained meltage was quenched on a stainless steel plate, and then pulverized (< 53 μm).

0.5 g of SiV or BG powders were soaked in 15 ml of a culture medium containing 10 wt% of foetal bovine serum and then incubated in a CO₂ incubator for 24 h. After the incubation, the sample was filtrated using a 0.2 μm PTFE filter. The obtained solution was diluted with the culture medium to set its Si concentration at 10 – 50 ppm.

Mouse osteoblast-like cells (MC3T3-E1) or human osteoblast-like cells (SaOS-2) were culture using each

Si-containing medium. The cell morphology was observed by staining actin in the cell with Alexa Fluor 488 Phalloidin. The cell proliferation was evaluated by colorimetry.

RESULTS AND DISCUSSION

The morphology of MC3T3-E1 and SaOS-2 cells was changed in both of the Si-containing medium, depending on the Si concentration. For example, in the case of 30 ppm, MC3T3-E1 cells exhibited a spindle shape in control (conventional medium) and SiV-medium, whereas they did a small radial shape in BG-medium. SaOS-2 cells showed a radial shape in control and BG-medium, whereas they did a spindle shape in SiV-medium. These changes in the cell morphology were found to depend on the Si concentration of each medium.

Results of the proliferation test for MC3T3-E1 cells demonstrated that the medium with 20 ppm of Si ions enhanced their proliferation in both cases of SiV and BG-medium. However, the dependence of the proliferation of SaOS-2 cells on the Si concentration was not the same as that of MC3T3-E1 cells. Thus, the stimulation effects of the soluble silica ions differed between different types of osteoblast-like cells.

The adhesion and proliferation of both cells were changed with the changes of not only Si concentration in the culture medium but also the silicate ion source materials. The silicate ion released from SiV contains amino groups in its structure and must form *T* groups. On the other hand, the silicate ion released from BG must form *Q* groups. These differences in ionic state of the silicate ions were supposed to relate to the effects on the osteoblast-like cell functions.

CONCLUSION

Two different types of osteoblast-like cells were cultured in the Si-containing media prepared using BG or SiV. Their adhesion and proliferation were influenced by the change of the Si concentration and the differences in materials (silicate ion source). This might be related to the ionic state of the silicate ions in the culture medium.

Atomic-scale Models of the Water-Bioactive Glass Interaction

Antonio Tilocca¹ and Alastair N Cormack²

¹Department of Chemistry, University College London, U.K.

²Inamori School of Engineering, Alfred University, USA

INTRODUCTION

The interaction with water is central for the biodegradation and the performance of bioactive glasses in a biological medium. This interaction eventually leads to release of key soluble species such as calcium, phosphate and silica, which play a role in both the bone-bonding and the activation of osteogenic cells.^{1, 2} Understanding the water-bioactive glass interaction at a fundamental level can support a thorough understanding of how these biomaterials work. Moreover, detailed data on the fate of water molecules absorbed in bioactive glasses can provide precious insight into the effects of sol-gel processing on the atomic-scale glass structure.³ We discuss atomistic simulations⁴ aimed to investigate the interaction of the glass surface with water monomers,⁵ in order to probe the activity of individual surface sites, as well as simulations of the extended interface between the glass and an aqueous contact medium.^{6, 7} This information allows us to build and analyse large models of the surface of glasses of different composition, thus revealing links between surface structure and bioactivity.⁸ These studies have allowed us to identify the role of specific surface sites in the key steps of the bioactive mechanism, namely ion release and dissolution of the silicate network

EXPERIMENTAL METHODS

Ab-initio Molecular Dynamics (AIMD) simulations of water on model 45S5® bioactive glass surfaces have involved probing the active surface sites based on their interaction with an adsorbed water molecule. The water probe was released next to a specific site, such as a ring, an unsaturated ion, or a siloxane bridge, and then left free to locate a stable adsorption minimum by AIMD. We also deposited a liquid film of water molecules on the surface and examined the dynamics and reactivity at the interface.⁷ Thereafter, based on the potential activity of specific sites revealed by AIMD, we have employed classical MD simulations⁹ to compare the surface features of bioactive and bio-inactive compositions.

RESULTS AND DISCUSSION

The models of the water monomer-45S5 surface highlighted that unsaturated Si atoms represent the strongest surface sites, able to induce spontaneous water dissociation at room temperature, provided that they are combined with a proton acceptor such as a non-bridging oxygen. Additional strong surface adsorption sites are located near to Na⁺ or Ca²⁺ cations, which appear to be directly involved in the glass dissolution mechanism, by providing favourable adsorption pathways that allow water to penetrate under the glass surface (Figure 1). Small (2- or 3-membered) silica rings are also common features of the 45S5 Bioglass® surface, not frequently found in the bulk. The accurate determination of

minimum energy paths⁵ and the direct AIMD simulation of the interface at room temperature⁷ shows that, despite a favourable energetic balance, opening of these rings upon water dissociation is hindered by a significant energy barrier.

Figure 1: (left) Model highlighting penetration of a water monomer within the 45S5 surface. (right) Model of the 45S5-liquid water interface

CONCLUSIONS

The fragmented bulk structure of highly bioactive glasses⁹ is further reflected on the surface, which contains additional features that contribute to the favourable dissolution and biological properties. The presence of favourable alternative water adsorption sites, combined with kinetic effects, can stabilise some of the small rings exposed on the surface, protecting them from hydrolysis long enough for them to act as nucleation sites of dissolved Ca²⁺ and PO₄³⁻ ions in the initial stages of the bioactive fixation mechanism, as it has been proposed.⁹

INTRODUCTION

Pioneering work by Hench showed that bioactive glasses based around calcium silicate compositions were exciting materials for tissue replacement and regeneration applications¹. The structures of these materials are important in conveying their properties. The potentially chemically complex and structurally disordered nature of these materials make their accurate characterisation somewhat problematic. Solid state NMR is an element specific probe technique with good sensitivity to the local atomic scale structural environment and has been applied to a wide range of materials². In bioactive sol-gel prepared calcium silicates ²⁹Si and ¹H have been the most studied nuclei³. However a multinuclear NMR approach opens up new insights including of the reaction with simulated body fluid (SBF) via ³¹P, direct probing network ordering and condensation via ¹⁷O and most challengingly of the siting of calcium via ⁴³Ca. ⁴³Ca has a very small magnetic moment (termed a low- γ nucleus) and also has a low natural abundance (0.14%) which lead to very low sensitivity. Nevertheless good quality NMR spectra at good signal-to-noise can be obtained, even at natural abundance, by using large samples. This contribution will review some of the solid state NMR applications to calcium silicate based sol-gel formed bioactive systems.

EXPERIMENTAL METHODS

Sample preparation has been previously described⁴. To overcome the sensitivity problems arising from the low natural abundance of ¹⁷O (0.037%) isotopically enriched H₂O was used in the preparation. NMR experiments were carried at 8.45 and/or 14.1 T at the Larmor frequencies of the observed nucleus. ¹⁷O MAS NMR spectra were collected using an echo sequence (θ - τ -2 θ)⁵ with a Bruker 4 mm probe spinning at 12 kHz. ¹H, ²⁹Si and ³¹P were all collected using a single pulse acquisition sequence. ⁴³Ca MAS NMR was performed using a 9.5 mm probe equipped with a low- γ box with spinning at 4 kHz and recycle delay 1 s using naturally abundant samples.

RESULTS AND DISCUSSION

¹⁷O has characteristic NMR parameters that are very sensitive to the local structural environment and can therefore directly probe the network ordering of sol-gel prepared silicate systems. ¹⁷O NMR can provide quantitative information about the bridging oxygen (BO):non-bridging oxygen (NBO) ratio of the silicate network. At a low heat treatment temperature (120°C), the network structure is dominated by bridging oxygen (Si-O-Si) with contributions from Si-OH at around 0 ppm. This indicates that Ca²⁺ ions are not yet intimately

part of the silicate network, probably remaining as a layer of the initial salt on the primary silica particles.

At higher temperatures ($\geq 500^\circ\text{C}$), NBOs become increasingly important, indicating that calcium now plays a central role and begins to dominate changes of the silicate network. The calcium species migrate into the silicate part of the materials, acting as a network modifier and gradually breaks down the silicate network by forming NBO. Changes in spectral parameters allow the oxygen sites to be clearly described and different species distinguished. An increase in the NBO resonance intensity is as a result of a modification of the silicate network and can be correlated to increases in the intensity of the ²⁹Si Q² and Q³ resonances.

The effects of increasing the heat treatment temperature on the direction of change of the chemical shifts is the same as increasing Ca/Si ratio, since both result in an increasing NBO resonance and decreasing polymerisation of the silicate network. The increasing chemical shifts can be understood as the consequences of deshielding effects when more calcium cations migrate into the silicate network forming large numbers of NBO with more deshielded oxygen sites, subsequently also influencing the surrounding BO resonances. ⁴³Ca can follow changes in the nature of the calcium site with increasing heat treatment.

Subsequent reaction of stabilised calcium silicate systems with SBF can also be followed by solid state NMR. ¹⁷O and ²⁹Si show changes in the network connectivity as the reaction progresses. On immersion with SBF there is rapid release of Ca²⁺ and decrease of NBO content. Also release of Ca²⁺ could open ways to surface hydration by ion exchange with H⁺ from the solution resulting in significant increase of Si-OH concentration on reaction. ³¹P NMR shows the formation of an apatite layer.

Chloride Containing Bioactive Glasses

Robert Hill, Natalia Karpukhina and Xiaojing Chen

¹Dental Physical Sciences Dental Institute Barts and The London QMUL LONDON E1 4NS.

r.hill@qmul.ac.uk

INTRODUCTION

In our previous studies we investigated fluoride containing bioactive glasses¹⁻³. Fluoride ions form F-Ca(n) species in the glass. They result in reduced glass transition temperatures and bioactive glasses that form fluorapatite as opposed to hydroxycarbonated apatite. The chloride ion is substantially larger than the fluoride ion, which is similar in size to the oxygen anion. Chloride ions are naturally present in the body. The present study investigates the addition of calcium chloride to melt derived glasses. It is hypothesised that addition of calcium chloride will expand the glass forming range compared to calcium fluoride and will reduce the glass transition temperature and facility glass dissolution and apatite formation.

EXPERIMENTAL METHODS

The glass compositions were based on an initial glass with the composition in mole% of 38.1SiO₂6.3P₂O₅55.5CaO. To this glass was added increasing amounts of CaCl₂. The glasses were prepared by mixing the appropriate amounts of SiO₂, P₂O₅, CaCO₃ and CaCl₂ and melting in an electric furnace at temperatures between 100 and 1300°C depending on composition for 1Hr. The molten glass was fritted, dried, ground and sieved to give a particle size < 38 microns.

The glass powder produced was characterised by XRD high temperature DSC, ³¹P solid state NMR spectroscopy and FTIR spectroscopy. Selected glasses were heat treated to the observed crystallisation temperatures from the DSC experiments and XRD carried out.

The glass powder was immersed in Tris buffer pH 7.4 and their in vitro bioactivity assessed using Simulated Body Fluid. The solutions were analysed by ICP-OEM and apatite formation followed by XRD, FTIR and ³¹P ssNMR. The experimental techniques employed have been described fully for the related fluoride glasses³.

RESULTS AND DISCUSSION

All the glasses were optically transparent. The glasses exhibited weak diffraction lines corresponding to a mixed hydroxyl/chloroapatite upon XRD but were amorphous by ³¹P ssNMR. The presence of a mixed hydroxylchlorapatite arose from surface reaction with water during the XRD. The glass transition temperature reduced from 793 to 601°C on incorporating 20 mole% CaCl₂.

The glasses containing CaCl₂ crystallised to Calcium Chloroapatite, which is the first time this phase has been observed crystallising from a glass.

Incorporating CaCl₂ accelerated the dissolution of the glass and resulted in very rapid release of ions and rapid apatite like phase formation. Apatite like phases were detected in under three hours immersion by XRD, ³¹P ssNMR and FTIR (Figure 1). The apatite like phase formed was not chlorapatite, but is thought to be a phase with a composition between that of octacalcium phosphate and hydroxycarbonated apatite.

Figure 1 FTIR Spectra of a 4.5mole% CaCl₂ Glass after immersion in Tris buffer

The addition of CaCl₂ has a similar influence on glass properties as CaF₂. Bioactive glasses containing CaCl₂ overcome the disadvantages of high CaF₂ contents bioactive glasses, notably the formation of CaF₂ at the expense of apatite on dissolution and their tendency to crystallise during quenching. Furthermore unlike fluoride there are no restrictions on the amount of chloride that may be added to toothpastes.

The CaCl₂ glasses probably dissolve more rapidly compared to the equivalent CaF₂ glasses as a result of the larger ionic size of the chloride ion relative to fluoride that probably results in a more open glass structure that facilitates ion exchange and dissolution.

CONCLUSION

Calcium chloride containing bioactive glasses have been produced that show very rapid apatite like phase formation in Tris buffer and SBF on immersion.

INTRODUCTION

The changes in the structure of 45S5 Bioglass and its heat-treated versions upon strontium substitution were investigated (1).

EXPERIMENTAL METHODS

The structures were investigated by solid-state multinuclear nuclear magnetic resonance, X-ray diffraction and differential scanning calorimetry. A series of the melt-derived glasses with strontium gradually substituted for calcium (0, 25, 50, 75 and 100%) on a molar basis was synthesised.

RESULTS AND DISCUSSION

T_g and crystallisation temperature decreased upon Sr substitution. Glasses with 75 and 100% of Sr substitution showed a minor crystalline phase. ³¹P MAS-NMR showed that phosphorus is present as orthophosphate in the entire glass series; ²⁹Si MAS-NMR data showed a predominantly Q² silicate network. A small step change in the position of the ³¹P and ²⁹Si MAS-NMR signals found between the glasses with 25 and 50% of Sr substitution is explained by an increase in the ring-type fraction of the Q² silicate glass over the mainly chain topology in the original 45S5 glass.

On heat treatment combeite silicate phases were identified. The polymerisation degree of phosphorus

increased and in addition to orthophosphate amorphous pyro- and meta-phosphate species were observed, the amount of which reduced with strontium substitution. Above 800°C, changes in ³¹P MAS-NMR spectra suggested that several phosphate containing phases, e.g. Na₃PO₄, crystallised and the fraction of the remaining glass became below the detection limit. In contrast to the Sr containing glasses, in the original 45S5 composition a significant fraction of phosphorus remained amorphous even after heat treatment at temperatures above 800°C.

CONCLUSION

The increasing substitution of Sr for Ca promoted crystallisation of a Sr-substituted combeite and the formation of ring structures in the glass.

INTRODUCTION

Sol-gel bioactive glasses were first developed in the early 1990s, and the early work of Hench *et al.* demonstrated that their inherent nanoscale porosity increased apatite phase formation and bone bonding compared to melt-quenched glasses of similar composition¹⁻³. Bioactive glasses bond with host bone and their dissolution products can stimulate new bone growth¹; this bonding is thought to be facilitated by the reaction with body fluid which results in the formation of a hydroxycarbonate apatite (HCA) surface layer on the glass. Furthermore, the sol-gel process is widely thought to produce more homogeneous glass structure than melt-quench analogues since the silica network forms by a condensation reaction, usually of hydrolysed tetraethyl orthosilicate (TEOS), under constant stirring. However, Ca rich regions can occur in bulk sol-gel glasses⁴. Calcium nitrate and triethyl phosphate (TEP) are conventionally used as the precursors for introducing calcium and phosphate, respectively, although alternative calcium sources such as calcium chloride⁵, calcium acetate and calcium methoxyethoxide (CME) have been investigated⁶. The aim of this study is to investigate the evolution of the overall 58S structure, particularly focussing on the role of phosphate and the formation of an orthophosphate phase during the sol-gel synthesis. The development of the glass structure is compared with samples using different calcium precursor phases, and the effect of HF is investigated in the foaming process leading to porous scaffold production.

EXPERIMENTAL METHODS

Bioactive sol-gel glasses were made to the bioactive 58S (60 mol% SiO₂, 36 mol% CaO, 4 mol% P₂O₅) composition. Three calcium precursors CaCl₂, Ca(NO₃)₂•4H₂O, and calcium methoxyethoxide, Ca(OCH₂CH₂OCH₃)₂ (CME) were compared. Sol-gel solutions were gelled with and without hydrofluoric acid (HF) and different heat treatments were applied to the gelled samples. Each sample was characterised for elemental composition (ICP-OES), surface area (BET) and pore size (BJH), and further analysed using FTIR and XRD methods. Multinuclear ¹H, ¹³C, ¹⁹F and ³¹P solid state MAS NMR measurements were undertaken at 11.7 T using a Bruker Avance III spectrometer, while the accompanying ²⁹Si measurements were performed at 7.05 T on a Varian Infinity Plus spectrometer.

RESULTS AND DISCUSSION

Solid state MAS NMR and X-ray diffraction (XRD) studies show that phase separation was observed during conventional synthesis of 58S (60 mol% SiO₂, 36 mol%

CaO, 4 mol% P₂O₅) sol-gel glasses when triethyl phosphate (TEP) was used as the phosphate precursor and calcium nitrate tetrahydrate as the calcium source. The heat treatment of these samples to 400, 700 and 800 °C show the development of various phases, including the first reported observations of hydroxyapatite (HA) formation under these conditions. This observation is facilitated by the presence of phosphate anions which are charge balanced by calcium ions and clearly partitioned from the silica network (i.e. no Si-O-P bonds were established). The separation of the phosphate groups is attributed to the presence of water in the sol-gel process, the nature of TEP and calcium not being incorporated into the silica network until the gels were heated to at least 400 °C. Subsequent preparations using HF as a gelation catalyst induced the formation of a fluorapatite rather than HA. At all temperatures studied here samples synthesised with calcium methoxyethoxide (CME) as the calcium precursor phase were amorphous according to XRD, while the MAS NMR data showed some evidence of orthophosphate group and Si-O-P bond formation.

CONCLUSION

These studies demonstrate the first observations of HA formation during conventional sol-gel 58S synthesis using TEP as the phosphate precursor and calcium nitrate tetrahydrate as the calcium source. CME also performs as an excellent alternative to calcium salts for the incorporation of calcium into the silica network at processing temperatures below 60 °C, and for improved homogeneity of glasses stabilised at higher temperatures.

In this paper we shall review our recent research on forming of bioglass architectures using simultaneous flow of precursors through a device which can contain several co-axial needles and operates in an electric field. In particular, research involving sol-gel and electrospinning technique combinations will be described. The co-flow in different situations can be made to jet and produce particles or tubes. In addition, silver ions can be accommodated in the glass precursor so that the Si-O-Si network forming process can be manually interfered at an atomic level, and the bioglass nanotube wall structure can be manipulated, from dense to a 'lace-like' structure (Fig 1a).

The synthesis of silica, a bioglass with pure SiO₂ contents in some extents, nanoparticles with a variety of mesoporous structures will be elucidated by demonstrating how nanoscale pores with different curvatures can lead to drug releasing kinetics being controlled. The process can also be used to form bioglass tissue engineering constructs and drug delivery vesicles, which can also be multifunctionalized by inducing different functional counterparts (i.e. up-conversion luminescent factors) due to its unique amorphous structural characteristics. In summary, the bioglass processing and forming described is useful to the interface of physical and life sciences, engineering and medicine, and examples of future prospects the process offers will be discussed.

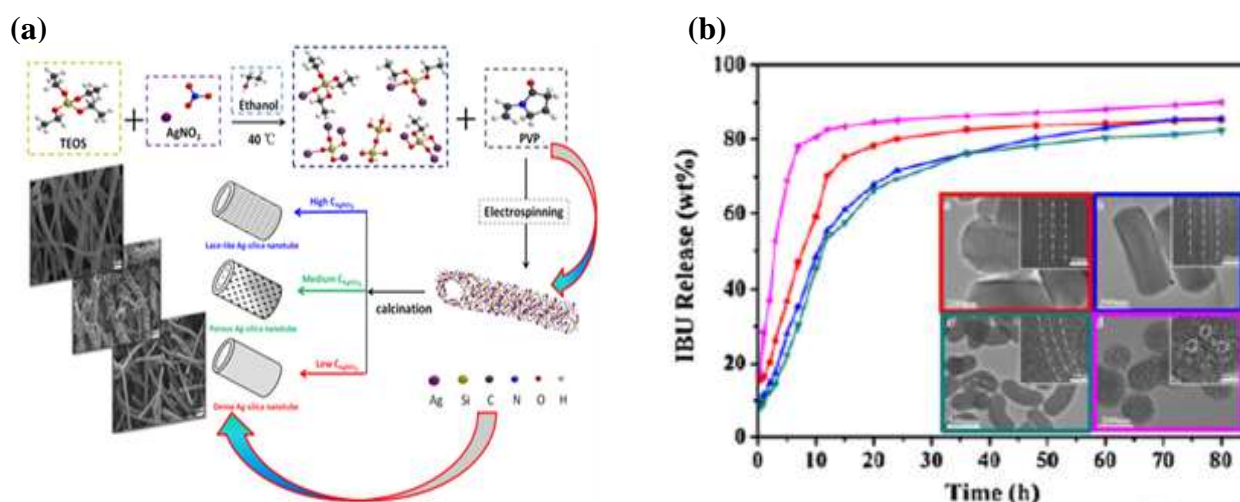

Figure 1 (a) The form procedures of bioglass nanotubes with well-controlled wall structures, and (b) silica particles with different drug releasing kinetics due to the mesoporous characteristics.

INTRODUCTION

Bioactive glasses can bond to bone or dentin by forming a hydroxycarbonate apatite (HCA) layer on their surface. *In vitro*, simulated body fluid (SBF) is often used to quantify HCA nucleation [1] and has led to the development of a standardized test (ISO/FDIS 23317, "Implants for surgery – *In vitro* evaluation for apatite-forming ability of implant materials"). Unfortunately the standard is not appropriate for all bioactive glasses: it is based on a fixed surface area to SBF ratio, favouring monoliths and making the assessment of powder like or mesoporous (e.g. sol-gel) glasses difficult. It was also a static test. This study aims to compare a modified method, based on fixed mass to SBF ratio under agitation, to the existing ISO standard. A round robin study on the proposed method was carried out in 8 laboratories in 7 countries on several commercially available bioactive glasses of known composition. The method was also further modified to test toothpaste containing bioactive glasses, Sensodyne Repair & Protect (SRP) containing NovaMin®, GlaxoSmithKline, UK.

EXPERIMENTAL METHODS

A ratio of 75 mg of glass powder to 50 ml of media was used and agitated at 120 rpm in an incubating orbital shaker set at 37°C. The pH and temperature of the media was verified before use. The samples were immersed in media for 8 different time points at 0h, 4h, 8h, 24h, 72h, 1week, 2 weeks, 3 weeks and 4 weeks. At the end of each time period, the sample was removed from the incubator and the solids were collected by filtration. The powder was washed with acetone to terminate the reaction and dried at room temperature for 24 h and analysed by FTIR, XRD and SEM. The filtered solution was analysed by ICP. Each sample was tested in triplicate. For toothpaste, a similar method was used except that artificial saliva (AS) was used as a media and powders were collected by centrifugation and freeze-drying.

RESULTS AND DISCUSSION

Commercially available melt derived glasses (45S5, NovaBone, BonAlive, 13-93 and StronBone) and a sol-gel derived glass (TheraGlass) were immersed in SBF using the presented method where the concentration of glass in the media is fixed as opposed to the ISO where the surface area defined the amount of media used. A good agreement in the kinetics of nucleation of HCA among the different laboratories was found as shown in

Figure 1. Results were also compared with the standard. The proposed method exhibited higher dissolution of silica and calcium and a more defined decrease in phosphorus concentration (ICP) when HCA nucleated. The 13-93 composition is of particular interest as it has good results *in vivo*, but using the ISO standard HCA did not form on the surface until after 2 weeks in SBF. In the modified test apatite formed between 3 days to 1 week (XRD and FTIR). The effect of the morphology was also studied by looking at the dissolution behavior of 13-93 shaped into fibers and disks. Using the adapted method, analysis of the bioactivity of bioactive glass in toothpaste was proven to be possible. In this particular case, SRP, containing NovaMin®, was immersed in artificial saliva using the same glass to media ratio. HCA was found to nucleate on the bioactive glass after 2 hours of immersion in AS.

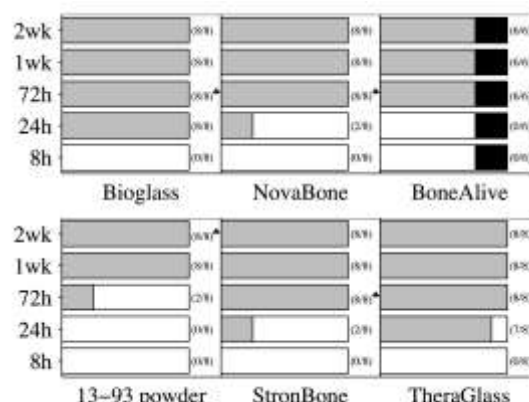

Fig. 1 – Summary of the different rate of HCA nucleation from the different laboratories for the different composition tested (* represents the rate obtained with the ISO methodology). Only 6 out of 8 laboratories tested BonAlive. Due to its high surface area (~80m².g⁻¹), TheraGlass was not tested using the ISO method as surface area was too high.

CONCLUSION

This proposed concentration-based method to assess the bioactivity *in vitro* of bioactive glasses seems to be more appropriate as high surface area and conditioned glasses are being developed as future biomaterials

INTRODUCTION

We have previously demonstrated that the association of Total Bone Marrow (TBM) and Biphasic Calcium Phosphate (BCP) is the best combination to regenerate bone in irradiated area.¹ Recently, Stromal Vascular Fraction from adipose tissue (SVF) has been described as an alternative to TBM as a source of mesenchymal stem cells.² Studies showed that SVF could promote osteoformation in healthy bone.³ The subject of this study was to identify the capacity of the SVF to induce new bone formation in irradiated area.

EXPERIMENTAL METHODS

Four weeks after an external 20 Gy of irradiation on the hind limbs of 20 rats, 4 bone defects were created per animal and filled with SVF or TBM, associated or not with BCP. Three weeks after implantations, the bones were removed. Histological and scanning electron microscopy analyses were performed to obtain qualitative and quantitative analyses. The different conditions were compared using Mann & Whitney tests for unpaired comparisons after validation by an analysis of Kurskal & Wallis.

RESULTS AND DISCUSSION

The BCP-TBM mixture significantly improved bone ingrowth ($p < 0.05$). The BCP-SVF mixture did not provide new-bone formation over and above that induced by BCP alone (Figure 1).

Fig. 1. Bone ingrowth in osseous defects (* $p=0.021$).

However, the histological staining of blood vessels showed that the BCP-SVF association induced more angiogenesis than BCP (Figure 2).

Fig. 2. BCP-SVF association: specific CD31 labeling of blood vessels (arrow heads).

Instead of the lack of vascularisation, our results suggest that the lack of cytokines and growth factors in the SVF could limit bone formation when compared to TBM in irradiated bone.

CONCLUSION

Despite the capacity of SVF to form blood vessels in irradiated bone defects, TBM associated to BCP appears to be the most efficient combination for bone reconstruction after radiotherapy today.

The control of cell-material interactions is still challenging, as in vivo, cells evolve in a complex environment regarding both biochemical signals and structural organizations. Now it is well established that proteins play a pivotal role in this issue and that the control of their behavior at interfaces is crucial. In this context, the emergence of smart materials that “spontaneously” respond to environmental stimuli has opened new routes for the control of surface properties, particularly, the behavior of proteins at the solid-liquid interface.

In the present study, we report on the design of thin film, which is sensitive to physicochemical changes of the environment. For this purpose, we used the layer-by-layer (LbL) assembly technique to incorporate block copolymers of PAA and PNIPAM, with tunable and well-controlled block lengths of each segment. The combination of ellipsometry, quartz crystal microbalance (QCM-D) and infrared data revealed the possibility to build up (PAH/PAA-PNIPAM)_n multilayers. Furthermore, it appears that the presence of PNIPAM moieties did not affect the mechanism of multilayers growth.

The stimuli-responsive properties of the LbL films were examined by monitoring the adsorption of proteins by

means of QCM-D and fluorescence measurements, while varying (i) temperature, (ii) pH, (iii) ionic strength, or (iv) a combination of the above parameters. Results showed that the temperature strongly influences the amount of adsorbed proteins, in accordance with the expected behavior of PNIPAM. Interestingly, adsorption/desorption cycles revealed the ability of the films to switch from favorable to unfavorable configuration towards protein adsorption. In addition to the successful design of stimuli-responsive LbL films, the mechanism of protein adsorption is profoundly examined, as it seems to be more complex, compared to tests performed on “common” flat surfaces. This is due to the fact that physicochemical changes (stimuli) influence, at the same time, the properties of the LbL films, made with weak polyelectrolytes. Indeed, the protein adsorbed amount estimated by fluorescence measurements suggests that various processes may occur at the interface, such as protein aggregation and/or interdiffusion within the films, depending on the pH and the ionic strength of the solution, etc.

This research is conducted within the frame of the International Doctoral School in Functional Materials funded by the ERASMUS MUNDUS programme of the European Union.

Tissue engineering creates new basis for scientific research in cell-biomaterial interaction

INTRODUCTION

"Scientists study the world as it is, engineers create the world that never was" says the well-known quotation by Theodore von Karman. Working on the new possibilities in tissue replacement and regeneration, tissue engineers create non-standard experimental systems based on the combination of cells and artificial materials. In the present study two selected examples of the influence of the materials on the differentiation of adipose derived stem cells (ADSC) are given. In the first one, more advanced differentiation of ADSC toward the osteogenic phenotype has been observed in 3D scaffolds as compared to the standard 2D culture surfaces. In the second one – materials of different stiffness were used as a support for cells in culture.

EXPERIMENTAL METHODS

Human ADSC obtained from liposuction were investigated. PCL/TCP composite scaffolds were used as the 3D system, while polyacrylamide and polydimethylsiloxane were used to obtain the support for cells - differing in stiffness. In the first system the observation was performed on day 21 and 42 and the markers of the advanced differentiation were detected, i.e. osteocalcin (Western blot) and mineralization (specific fluorescence staining). Observation of the role of the stiffness was performed on day 7 – so as to maintain a one-layer culture. Therefore, the early osteogenic markers were taken into account, i.e. RUNX2 (gene expression by real time PCR) and alkaline phosphatase (ALP) (gene expression by real time PCR and the enzyme activity).

RESULTS

Fig. 1 shows abundant mineralization (green) on the 3D PCL/TCP scaffolds on day 21 (A) and day 42 (B); no mineralization on the 2D standard culture surface on

day 21(C) and modest (compare to B) mineralization in 2D on day 42 (D); scaffold without cells is shown in the upper left window.

Fig. 2 shows Western blot – osteocalcin-up, and β -actin, as a reference-at the bottom; from the left: undifferentiated cells, control, i.e. ADSC cultured for 21 days in the medium enriched with vit. C, 2D or 3D culture in osteogenic medium on day 21 or 42.

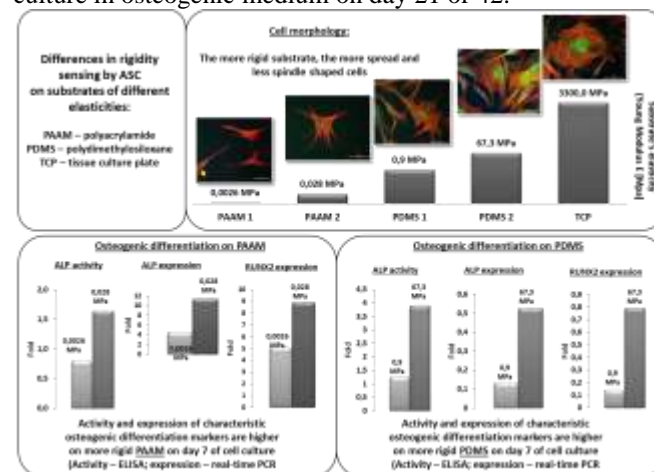

Fig. 3 stiffer material - better organized cell morphology (actin - red, vinculin – green), higher expression of RUNX2 and ALP genes and higher ALP activity.

DISCUSSION AND CONCLUSIONS

Both applied systems promoted ADSC osteogenic differentiation. The results were confirmed using the materials from several various (at least four) patients (informed consent was obtained). However, any definite statements from such observations are limited by the specific conditions of the particular experiments. The latter is a common weakness of the original reports in the field. It seems that tissue engineering is still rather at the stage of collecting data, while more general observations as well as the understanding of the particular mechanisms lying behind the observed phenomena are not yet achieved. In a way, tissue engineers, using new experimental systems have *"created the world that never was"*. It gives room for more specific *"scientific study"* in the field.

Wear and Friction of PEEK and CFR-PEEK Materials for Cervical Total Disc Replacement Bearings

Ksenija Vasiljeva¹, Phil Hyde¹, John Fisher¹, Richard Hall¹

¹ University of Leeds, Woodhouse Lane, Leeds, UK, k.vasiljeva@leeds.ac.uk

INTRODUCTION

PEEK (poly-ether-ether-ketone) and CFR-PEEK (carbon-fibre reinforced PEEK) polymers have been identified as a potential bearing material for use in cervical total disc replacement (c-TDR). However, there is limited knowledge concerning the wear and friction characteristics of PEEK bearing combinations. A recent study suggested that CFR-PEEK articulating against itself produces much less wear compared to conventional ultra-high molecular weight polyethylene (UHMWPE) on cobalt chromium (CoCr) [1]. The aim of this study was to investigate the wear and friction properties of medical grade PEEK and CFR-PEEK under cervical loading conditions and all bearing combinations, using conventional UHMWPE on CoCr as a baseline control.

EXPERIMENTAL METHODS

Wear and friction behaviour of PEEK and CFR-PEEK was studied using simple geometry pin-on-plate reciprocating wear test. Wear was studied using bearing combinations as follows: PEEK pin against PEEK plate (n=5), PEEK pin against CFR-PEEK plate (n=6), CFR-PEEK pin against PEEK pin (n=6), CFR-PEEK pins against CFR-PEEK plate (n=5). Contact pressure was 1.6MPa resulting from an 80N load and stroke length was 28mm at 1Hz with rotation applied to pin.

Friction was measured using all four possible combinations of PEEK and CFR-PEEK using n=6 except PEEK on PEEK experiment (n=16). Samples were tested at 4 mm/s sliding speed and 1MPa contact pressure. In both tests 25% diluted bovine serum was used as lubrication and a UHMWPE pin articulating against CoCr plate (n=6) was used as a reference control material.

RESULTS AND DISCUSSION

PEEK on PEEK and CFR-PEEK on CFR-PEEK had similar wear factors to the control bearing (Figure 1). Wear factors for CFR-PEEK on CFR-PEEK reduced with every 0.3 million cycles, suggesting bedding in wear was present. At the same time CFR-PEEK on PEEK and vice versa showed almost 10³ times higher wear than UHMWPE on CoCr.

The similarity in wear between PEEK on PEEK and UHMWPE on CoCr was also demonstrated by Grupp et al. [1] for a total disc replacement. However, in contrast to this study, Scholes et al [2] found CFR-PEEK on CFR-PEEK wear was lower than UHMWPE on CoCr. Friction coefficient for all material combinations was much higher than the control (Figure 2). Coefficient values ranged from minimum 0.4 for CFRP on PEEK to maximum value of 0.5 for PEEK on PEEK.

Figure 1 Pins and Plates wear factor (log scale) for PEEK and CFRP material combinations and UHMWPE pin on CoCr (control).

Figure 2 Friction coefficients for PEEK and CFR-PEEK combinations and UHMWPE on CoCr (control).

CONCLUSION

In comparison to the UHMWPE pin-on-plate control, both PEEK on CFR PEEK and CFR-PEEK on PEEK bearing combinations showed poor results in terms of wear. All PEEK and CFR PEEK bearing combinations demonstrated very high friction coefficients, approximately an order of magnitude higher than UHMWPE on CoCr.

INTRODUCTION

Biodegradable polymers are widely used in the field of regenerative medicine to replace and regenerate damaged tissues^{1,2}. Electrospun scaffolds, produced from these polymers, should be able to provide mechanical stability immediately after implantation and stay mechanically reliable until sufficient tissue is formed. The degradation speed and mode of scaffolds depend on the chemical characteristics of the used polymers and need to be studied to determine clinical applicability of new materials. Mechanical performance and degradation behaviour of supramolecular materials are tuneable by combining polymers with the hydrogen bonding ureido-pyrimidinone (UPy) or bis-urea (BU) moieties³. This study shows how mechanical and chemical stability of novel supramolecular electrospun scaffolds are affected by different degradation pathways.

EXPERIMENTAL METHODS

Our model includes accelerated enzymatic hydrolysis and oxidative degradation pathways. Mechanical (n=3 per time point), chemical (n=1 per time point) and morphological (n=1 per time point) properties of polycaprolactone (PCL) based electrospun materials with UPy or BU moieties were investigated during degradation, while a conventional electrospun PCL scaffold served as a reference material. Time points were chosen up to 56, 96, and 400 hours for enzymatic lipase (100U/ml), cholesterol esterase (10U/ml), and oxidative degradation (0.1M CoCl₂+ 20% H₂O₂), respectively.

RESULTS AND DISCUSSION

The properties of the conventional PCL scaffold are significantly affected by enzymatic degradation (Fig. 1A and E), with severe mass loss (93%), decreased mechanical properties, and changes in fiber morphology compared to untreated scaffolds (Fig. 2A-B). As molecular weight (Fig. 1C) remained stable, surface erosion is assumed to be the mode of degradation. Supramolecular materials showed to be more stable against enzymatic degradation.

Degradation by oxidation demonstrated minimally affected conventional PCL scaffolds, while the supramolecular scaffolds showed broken fibers (Fig. 2C), moderate to severe mass loss, decreased mechanical properties and a decrease in molecular weight (Fig. 1B, D and F). These results suggest that supramolecular materials, as well as conventional PCL, will degrade after implantation, however by a different mode of degradation.

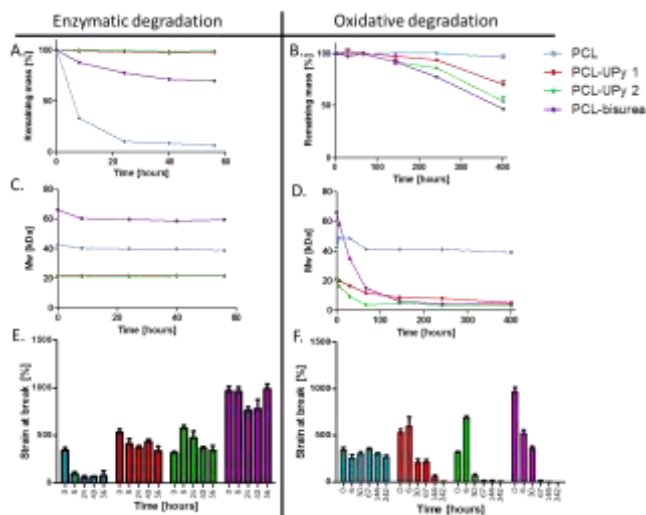

Figure 1. Characteristics of scaffolds during degradation.

Figure 2. SEM images of scaffolds. White scale bars represent 20 μ m.

CONCLUSION

Developed *in vitro* tests show that the conventional PCL scaffold is more prone to enzymatic degradation, while the supramolecular scaffolds are more prone to oxidative degradation. The *in vitro* data obtained in this study will be correlated to *in vivo* data to obtain more insight into *in vivo* degradation pathways and used to predict degradation properties of new materials after implantation to assess clinical applicability of new materials.

Characterising the Effects of Different Sterilisation Techniques on Electrospun Fibre Scaffolds

Lucy A Bosworth and Sarah H Cartmell*

School of Materials, The University of Manchester, UK

*sarah.cartmell@manchester.ac.uk

INTRODUCTION

Scaffolds that are intended as future medical devices ultimately require sterilisation and validation of their sterility prior to being classed as safe for human use and implantation. The International Organisation for Standardisation (ISO) have developed (and maintain) several standards for sterilisation techniques that are recognised by regulatory bodies, such as the Medical Device Directive. Sterilisation is necessary for the elimination of bioburden (microorganisms) that may be present on the scaffold's surface or within the material bulk¹. Without this eradication, the success of the implant could be severely compromised due to infection. Accepted sterilisation processes can significantly affect the material properties of the scaffold and if not addressed early in the project timeline can lead to the research never translating from the bench to the clinic.

This study investigated the effects of different sterilisation methods on the material properties of electrospun fibre scaffolds.

EXPERIMENTAL METHODS

PCL (Purac - Purasorb PC12) was dissolved in 1,1,1,3,3,3-hexafluoroisopropanol (HFIP; Sigma) at 10 %w/v and electrospun (20 kV, 1 ml/hr, 20 cm). Aligned fibres were collected on a rotating mandrel (600 RPM). Fibres were cut into strips (20 mm* x 3 mm) with their alignment parallel to the long edge (*30 mm for tensile testing). Scaffolds were subjected to different types of sterilisation; gamma irradiation – 15 kGy (+10 % tolerance), 25 kGy (+10 %), 50 kGy (± 10 %); ethylene oxide (EO, double pass); submersion in ethanol (50, 70, 90 and 100 %v/v in distilled water); and surface radiation by ultraviolet light (UV) for 30 mins. Synergy Health were contracted to undertake gamma irradiation and EO sterilisation. Ethanol and UV treatments were performed in-house. Sterilised scaffolds were subjected to material characterisation and compared to non-sterilised scaffolds (virgin PCL), including molecular weight (Gel Permeation Chromatography (GPC), 0.2 %w/v in Tetrahydrofuran), and tensile testing (Instron 3344, 100 N load cell, 20 mm gauge length and 5 mm/min cross-head speed). Data were analysed using one-way ANOVA with Bonferroni post-tests where sample sets were compared to virgin PCL (Graphpad Prism v.5).

RESULTS AND DISCUSSION

Molecular mass distributions significantly decreased for all sterilisation processes compared to the virgin PCL scaffolds, suggesting substantial scissoring of the polymer chains had occurred (Fig.1).

Fig.1 – Molecular mass distributions for PCL scaffolds, where (A) demonstrates number average molecular weight (Mn) and (B) weight average molecular weight (Mw). Data presented as mean \pm standard deviation (n=5); virgin PCL samples significantly different to all other scaffolds (** $p < 0.001$).

Despite the molecular weight decreasing by more than half its original mass, the tensile properties remained relatively unchanged, with no notable differences observed in stiffness or strength for sterilised scaffolds compared to virgin PCL samples (Fig.2).

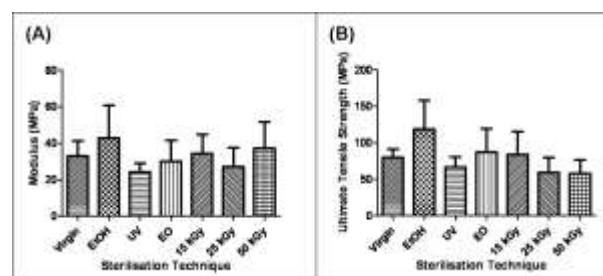

Fig.2 – Tensile properties of PCL scaffolds, where (A) indicates Young's Modulus and (B) Ultimate Tensile Strength. Data presented as mean \pm standard deviation (n=7); sterilised scaffolds demonstrated no significant difference compared to virgin PCL samples.

Being semi-crystalline in nature, scissoring of the amorphous regions of the PCL may have occurred preferentially, which could affect overall molecular mass whilst having minimal impact on mechanical strength¹.

CONCLUSION

Sterilisation can significantly impact the material properties of electrospun PCL scaffolds, in particular molecular weight, which in turn could markedly affect the degradation profile of this polymer. The effects of sterilisation should be considered early in the project in order to establish 'base-line' properties.

Novel Electric Discharge Assisted Mechanical Milling method as a mean of biomaterials synthesis in the Al-Zr-O system

M. Wyszomirska^{1*}, A. Calka², D. Wexler²

^{1*} Mechanical, Material & Mechatronic, University of Wollongong, Australia, mw966@uowmail.edu.au

² Mechanical, Material & Mechatronic, University of Wollongong, Australia.

Introduction:

Advanced materials manufacturing methods require clean non-pollution, high speed, precise process, and highly reliable final products. Many functional materials are traditionally synthesized by slow reaction processes that are energy and time consuming. In the present world there is strong demand on development of modern materials and materials processing methods that could offer rapid reaction rates, energy efficiency and be environmentally safe.

Electric discharge assisted mechanical milling (EDAMM)¹ is a new and exciting materials processing technique which combines the attributes of conventional mechanical milling with all effects generated by electric discharges. It is demonstrated that EDAMM can be used to synthesize a range of functional materials in a matter of minutes, rather than days. Possibilities of this method can be extended to biomaterials and lead to new, lower temperature and faster materials synthesis. In this work we are presenting the different aspects and results when processing pure Al and Zr metals and their oxides in different atmosphere and electrical conditions. Al-Zr phases are extremely difficult to obtain as they usually require high temperature, long and multistep processing², whereas studies on Al_xZr_yO_z properties will be first systematic investigation of this compound.

Figure 1 EDAMM processing chamber

Experimental methods

Al and Zr powders or their oxides were processed by a custom made EDAMM under different conditions. Their examination involved X-ray diffraction analysis for their chemical characterization, FESEM for the external shape and the cross-sectional, elemental analysis. In the later stage, the TEM examination will be also performed.

Results and discussion:

Two types of electrical conditions (AC,DC mode) as well as different atmospheres can be applied during EDAMM processing, determining the type of the chemical reaction. Pure metals processed in high purity Argon atmosphere enable fast and relatively low temperature synthesis of intermetallic phases such as

Al₂Zr, Al₃Zr, AlZr₃ etc. which are hard to obtain by conventional heat treatment². The same powders processed in the Ar/O₂ mixture enable to obtain Al and Zr oxides as well as ternary compounds of Zr-Al-O. Zirconium and Aluminium oxides, depending on the electric conditions, can form one or two phase material in which the main constituent of three element compound of Al-Zr-O with potential for biomedical applications. To our knowledge, there were no research focused on that ternary material, therefore its synthesis as well as properties may be of an interest of not only biomedical field. All the above mentioned synthesis can be performed in less than 5 min and much lower temperature than the conventional heat treatment, minimizing time consumption as well as the energy usage.

Figure 2 X-ray spectra of Al_xZr_yO_z compound processing route as an example of fast, 5-min compound synthesis

Conclusion

EDAMM is a novel method for materials processing in a powder form and allow fast and low temperature synthesis of materials. Optimization of the process includes the atmosphere of the process, mechanical impact and initial conditions of the powders, meaning the starting powders ratios and their mixing.

rlevato@ibecbarcelona.eu

INTRODUCTION

A major challenge in articular cartilage regeneration is to recapitulate the zonal organization of the tissue. Multimaterial structures that mimic it can be built with bioprinting, by 3D controlled deposition of strands of cell-laden hydrogels (bioinks)¹. Additional requirements to design functional osteochondral grafts are: 1) high cell content, which is hard to achieve with standard expansion methods and 2) inclusion of cues to guide cell differentiation in each specific gel layer.

A novel strategy to address these demands is to combine bioprinting with microcarrier technology, which allows for the extensive expansion of cells, while their phenotype can be controlled².

This work aims to fabricate novel living constructs via bioprinting of cell-laden microcarriers (MCs). Mesenchymal Stromal Cells (MSCs) cultured on polylactic acid (PLA) MCs were encapsulated in a gelatin methacrylamide bioink (GelMA), and cell homing on MCs was studied as promoter for bone differentiation and synthesis in 3D printed osteochondral grafts.

EXPERIMENTAL METHODS

PLA MCs (collagen I coated, mean diameter $\approx 120 \mu\text{m}$) were prepared via a green solvent-based method³. MCs were dispersed in GelMA/gellan gum solutions (10% w/v and 1% w/v, respectively) and the mixture was extruded and UV crosslinked. The compressive modulus was evaluated with a dynamic mechanical analyzer. MC-MSCs complexes in the hydrogel matrices were assessed for cell morphology (actin staining), viability (calcein AM/ethidium homodimer) and osteogenic differentiation (alkaline phosphatase activity, osteocalcin synthesis, and alizarin red staining of calcium deposits). Bioprinting was performed via layer-by-layer deposition of bioink strands with the Bioscaffolder system (SYS+ENG, Germany), combined with CAD/CAM software. The bioink included MC-MSCs precultured under static conditions or in a spinner flask bioreactor (BellCo, USA). Student's t-test was performed to assess statistical significance ($n=3$ or 5, $p<0.05$).

RESULTS AND DISCUSSION

GelMA/gellan gum loaded with up to 50 mg/mL MCs, was used as a printable, strand-forming bioink. MCs encapsulation increased the gel compressive modulus up to 2-fold. MSCs retained a spread morphology with well defined actin stress fibers and cell-cell contacts when expanded on the MCs surface and then suspended

in the hydrogel, (Fig.1A), whereas cells encapsulated in GelMA without MCs showed rounded morphology. Such control over cell shape and cytoskeletal organization in hydrogel matrices via addition of MCs has great potential in tuning cell bioactivity and extracellular matrix deposition⁴. In fact, MC-MSCs encapsulated in the gel supported osteogenic commitment of MSCs, inducing mineralized matrix deposition and improving osteocalcin secretion compared to MC-free controls. MC-MSCs complexes were viable after the gel printing and crosslinking. Bioinks loaded with MC-MSCs from spinner flask cultures permitted the fabrication of living constructs, with good shape fidelity, and with high concentration of cell-carrier complexes, which were homogeneously distributed (Fig.1B). Furthermore, a bilayered scaffold, representing an osteochondral graft, was printed with MC-laden gel as a subchondral bone layer, and a gel-only region recapitulating the cartilage zone (Fig. 1C).

Figure 1: (A) MC-MSCs used for bioprinting, after 4 h culture, (B) MC-cell distribution in the biofabricated construct and (C) MC-laden GelMA-based osteochondral graft.

CONCLUSION

MCs-laden GelMA/gellan gum was proven to be a promising composite material for biofabrication. MCs acted as a mechanical reinforcement for the soft gel. Encapsulation of MC-MSCs complexes -with improved cell adhesion and cell-cell contacts- was effective to improve osteogenic differentiation and to support bone matrix deposition. MCs culture is of great interest for MSCs expansion and scaling-up of bone-like tissues bioprinting. These are key findings to build advanced constructs for bone and zonal osteochondral regeneration.

INTRODUCTION

Low temperature calcium phosphate materials like cements have long attracted the attention in the biomedical field for their close resemblance both, in structure and composition to the mineral phase of bone. Cements can also be easily processed as scaffolds which make them excellent candidates in tissue engineering applications. One aspect though that scientists seek is to incorporate carbonate groups in the apatite lattice of these materials to improve their biological performance^{1,2}. The most common approach used to accomplish this goal relies in the incorporation of calcium carbonate in the formulation of cements. Unfortunately this often leads to unreacted calcium carbonate as second phase masking interpretation of the results. In this work we have developed a very fast, clean and reliable way of introducing carbonate groups by autoclave treatment of the cements in the presence of sodium hydrogen carbonate.

EXPERIMENTAL METHODS

Cement foams (CF) were prepared by mixing a solid phase consisting of 98% α -TCP and a 2% precipitated hydroxyapatite with a liquid phase consisting of 1% Tween 80[®] which, as surfactant, helped to introduce macroporosity. The foams were prepared with a liquid to powder ratio of 0.55 ml/g, injected into moulds (5x10 mm) and immersed in distilled water at 37°C for 10 days to complete setting. Carbonation of the foams was investigated using different methodologies: 1) by addition of NaHCO₃ in the setting media and allowing setting for 17 days; 2) by immersing an already set cement in NaHCO₃ followed by autoclave treatment for 30 min at 120°C and 1bar; and 3) by immersing a non-set cement in NaHCO₃ followed by autoclave treatment to achieve simultaneously setting and carbonate incorporation. To preserve the cohesion of the cements they were maintained for 8-15h in a humid atmosphere prior to immersion in water or the carbonate containing solution. All final products were characterized by X-ray diffraction, scanning electron microscopy, elemental analysis for total carbon determination and infrared spectroscopy.

RESULTS AND DISCUSSION

α -TCP undergoes a hydrolytic reaction by which it transforms into nano- or submicrometric calcium deficient hydroxyapatite (HA) crystals during setting. One can take advantage of this reaction to incorporate foreign ions such as carbonate. Figure 1 evidences the various degrees of carbonation achieved by the three different carbonation methods. As expected, carbonation of the pre-set material yielded lower carbonate contents as compared to the other routes

owing to the slow diffusion of carbonate in the already formed crystals. However, when carbonation took place during setting, carbonate uptake markedly increased up to approximately 15 wt%. The major difference between carbonating during cement setting at 37°C or in the autoclave was the time taken for the conversion of the α -TCP to carbonate-HA: from over two weeks it was reduced to an autoclave cycle of 30min. Thus, autoclaving not only provides a way for incorporating carbonate, but it also speeds conversion of α -TCP to HA. Any of the methods allow a fine tuning of the carbonate content as it can be observed from Fig. 1.

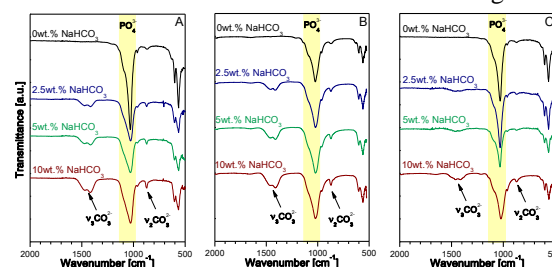

Figure1. IR spectra of CF in the various carbonation methods: during setting at 37°C (A); during setting in autoclave (B); carbonated after setting (C).

In terms of the nano/micro structure resulting from the various carbonation methods there are interesting differences as shown in Fig.2. The microstructure of the CF was preserved if carbonation was accomplished after cement setting (D) but it changed when carbonation and setting took place simultaneously (B, C). Smaller plate-like crystals were formed during carbonation at 37°C (B) as opposed to the larger crystals seen in the autoclave treatment (C).

Figure2. SEM images of: A) CF; B) CO₃²⁻ during CF setting; C) CF autoclaved for setting; and D) set CF carbonated in autoclave.

CONCLUSION

This work proves that it is feasible to fine tune the carbonate content of low- temperature HA foams in a reliable manner at different stages of cement setting.

Characterization and Biocompatibility of a Collagen/Hydroxyapatite-Microsphere Composite Scaffold for Bone Regeneration

Rahmat Cholas*, Sanosh Kunjalukkal Padmanabhan, Francesca Gervaso, Gayatri Udayan, Graziana Monaco, Alessandro Sannino and Antonio Licciulli

Department of Engineering for Innovation, University of Salento, Italy, rahmat.cholas@unisalento.it

INTRODUCTION

Bone is a composite organic-inorganic material with a complex multi-scale structure. Biomaterial scaffolds which are designed with a structural and chemical composition similar to native bone tissue have been shown to be promising for use as bone implants¹. Specifically, collagen (Col)/hydroxyapatite (HA) composite materials which closely resemble natural bone tissue possess good osteoconductivity and osteoinductivity and may provide the appropriate cellular microenvironment to facilitate bone regeneration. Importantly, the scale of the structural features of the material is an important consideration when designing a scaffold for bone growth, and prior work suggests that multi-scale structures, with defined features at the nano-, micro-, and macro-scales, contribute to the mechanical and biological properties of the material². In this study we incorporated HA microspheres (mHA) with well-defined nano-pores into collagen scaffolds containing a well-ordered interconnected micro- and macro-pore structure and evaluate the cytocompatibility. Attractive properties of this composite scaffold include the ability to load the microspheres for drug delivery and the controllability of the pore structure at various length scales.

EXPERIMENTAL METHODS

HA microsphere synthesis and characterization.

Microspheres were synthesized using a spray drying method. The slurry for spray drying was obtained by precipitating HA nano particle using $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ and H_3PO_4 precursors and maintaining a Ca/P molar ratio of 1.67. Transmission electron microscopy (TEM) analysis was carried out to investigate the particle size of the HA used for spray drying. The phase analysis, morphology and size of HA microspheres were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM) and particle size analyzer, respectively. The specific surface area and pore size analysis of the microspheres were determined by BET and BJH methods.

Composite scaffold fabrication and characterization.

Porous scaffolds were fabricated by freeze-drying a suspension of type I collagen with and without HA microspheres, followed by dehydrothermal crosslinking. The morphology of the scaffolds was studied using SEM. In order to evaluate the mechanical strength of the composite scaffolds, mechanical compression tests in PBS were performed on scaffolds with and without HA microspheres.

Cell culture and cytocompatibility. Scaffolds were seeded with the human osteosarcoma cell line, MG-63, and cultured for 1, 3, 7, and 15 days. Cytocompatibility was identified by the MTT assay and histological

staining. Statistical significance was determined using one-way ANOVA and Fisher's PLSD test.

RESULTS AND DISCUSSION

The XRD analysis of the microspheres revealed a pure HA phase. SEM demonstrated the microspheres to be uniformly rounded (Figure 1a) and particle size analysis gave distribution values D_{10} , D_{50} and D_{90} of 1, 6 and 13 microns, respectively. BJH analysis showed the microspheres to be mesoporous with an average pore diameter of 16 nm. SEM observations of Col/mHA scaffolds revealed HA microspheres embedded within a porous collagen matrix with a pore size ranging from a few microns up to 200 microns (Figure 1b), which was also observed by histological staining (Figure 1c). The mechanical strength (σ - ϵ initial slope) of the composite scaffolds was significantly higher than pure collagen scaffolds, indicating mHA do not disrupt the collagen fibre structure (5.53 ± 0.82 vs 3.27 ± 0.81 KPa). Cell proliferation measured by the MTT assay showed more than a 3-fold increase in cell number within the scaffolds after 15 days of culture for both pure collagen scaffolds and collagen-mHA composite scaffolds (no statistical difference with and without mHA, Figure 1d), suggesting that the integration of the mHA microspheres is compatible with MG-63 cell growth.

Figure 1.

CONCLUSION

A multi-scale collagen/HA-microsphere composite scaffold was fabricated with controllable structural features on the nano- micro- and macro-scale. The scaffold was found to support cell growth and may be a promising biomaterial for bone reconstruction as a non-load-bearing implant.

PEO Physicochemical Modification of Novel Low-modulus β -Ti Alloys Shows Comparable Cellular Behaviour to Commercial α - and $(\alpha+\beta)$ -Ti Alloys

Mehdi Golozar^{1*}, Constantin-Edi Tanase², Roger A. Brooks², and Serena M. Best¹

¹Cambridge Centre for Medical Materials, University of Cambridge, UK, mg628@cam.ac.uk

²Division of Trauma & Orthopaedic Surgery, Addenbrooke's Hospital, University of Cambridge, UK

INTRODUCTION

Surface modification of endosseous Ti implants at the nano-/micro-scale has been shown to enhance bone formation and encourage rapid osseointegration and biomechanical stability^{1,2,3}. Plasma Electrolytic Oxidation (PEO) creates a textured TiO₂ surface layer, suitable for orthopaedic applications. Among the three polymorphs of TiO₂ (anatase, rutile and brookite), anatase has been shown to enable rapid precipitation of HA in SBF⁴; hence, it is desirable to maximize the surface anatase content. Moreover, in comparison to α - and $(\alpha+\beta)$ -Ti alloys, β -Ti alloys have a modulus closer to that of natural bone, and thus potentially offer a lower stress shielding effect. This study explores the possibility of extending the application of PEO to novel low-modulus β -Ti alloys, while maintaining similar cellular activity as commercial α - and $(\alpha+\beta)$ -Ti alloys.

EXPERIMENTAL METHODS

PEO was conducted in a 10 kW KeroniteTM rig using the initial current density of 20 A·dm⁻² and 0.05 M Na₃PO₄ electrolyte. The electrolyte temperature was kept at 20±2°C. Coatings were produced on α -Ti, $(\alpha+\beta)$ -Ti6Al4V, β -Ti13Nb13Zr and β -Ti45Nb discs after 2, 5, 10, and 30 minutes. The physicochemical variations of the PEO coatings were characterised using SEM, XRD-Rietveld Refinement, Optical Interferometry (R_a and R_z), and Drop Shape Analysis. The influence of coatings on metabolic activity, proliferation and differentiation of human foetal osteoblasts was studied using alamarBlue, CyQuant and ALP, respectively. The effects on human foetal osteoblast mineralization (OsteoImage kit), collagen release (immunoblotting), and surface distribution of cells (immunofluorescence) were also investigated.

RESULTS AND DISCUSSION

The development of surface physicochemical features during PEO was found to be time dependent and caused primarily by micro-plasma discharges. The micro-plasma discharges and the resulting surface roughness, anatase content and hydrophilicity seemed to depend on the initial formation of an electrically insulating oxide layer. At longer processing times, the anatase/rutile ratios dropped, while hydrophilicity and roughness increased, Table 1. Uniform pore size distribution was observed for all four alloys, Figure 1(a-b). *In vitro* biological evaluation of the coatings showed similar osteoblast metabolic activity, proliferation and differentiation on all four alloys. Osteoblasts were evenly distributed on coating surfaces, Figure 1(c). Osteoblast mineralization appeared to be enhanced after 30 min, which may be associated with increased coating thickness, surface roughness and/or hydrophilicity.

"Table 1: Properties of PEO-coated Ti alloys"

Titanium Alloys	Modulus (GPa) ^{1,5}	Roughness, R_a [μ m]			
		2min	5min	10min	30min
$(\alpha+\beta)$ -Ti6Al4V	110-112	0.774	0.993	1.032	4.253
α -Ti	100	0.851	0.978	1.137	1.344
β -Ti13Nb13Zr	77-84	1.319	1.753	1.751	1.949
β -Ti45Nb	~62	0.453	1.086	1.831	2.188

"Figure 1: Surface topography of 10 min PEO-coated Ti45Nb ($R_a=1.78 \mu$ m and $R_z=17.72 \mu$ m), a-b. Osteoblasts are evenly distributed over the surface (Pha+DAPI after 3 days of human foetal osteoblast culture on such surface), c."

CONCLUSION

PEO was shown capable of producing rough anatase-rich TiO₂ films on α -, $(\alpha+\beta)$ -, and β -Ti alloys. The surface physicochemical properties (roughness, phase content and hydrophilicity) were found to depend on PEO processing time and substrate material. Regardless of the contrast in bulk mechanical properties (stiffness), metabolic activity, proliferation and differentiation of osteoblasts remained consistent for all four alloys. This suggests that PEO application can be extended to low-modulus β -Ti alloys offering a lower stress shielding effect, without compromising the biological activity.

tpasang@aut.ac.nz

INTRODUCTION

This paper presents a machining work performed on two biomaterials namely Cobalt-Chromium-Molybdenum (Co-Cr-Mo) and Titanium-Aluminium-Niobium (Ti-Al-Nb). These two alloys are known for applications on the dental area, and joint prostheses, respectively.

The objectives of this research are to study the milling performance of the above alloys, by measuring the forced required and by examining the milled surface as well as the chips produced.

EXPERIMENTAL METHODS

Lateral milling experiments¹, identical to milling on teeth, were conducted on two different alloys namely Cobaltan and TiAlNb (compositions in Table 1) using four types of drills made of tungsten carbide (WC). Three types of the drills were uncoated and the fourth type was coated with a diamond-like carbon (DLC) layer. The rotational speed used varied from 10,000 to 35,000 rpm with a feed rate fixed at 0.15 mm/second. Fig.1 shows the milling configuration and test mills.

Table 1. Nominal composition and hardness values

Alloy	Cr	Co	Mo	Ti	Al	Nb	Hv*
Co-Cr-Mo	65	29	6	-	-	-	365
Ti-Al-Nb	-	-	-	86	6	7	400

*Hv = Vicker's hardness

Cutting forces were measured and recorded during milling. The milling tests were carried out at room temperature without mill lubrication or cooling.

The surfaces of the drills, the workpieces and the chips were analyzed by scanning electron microscopy (SEM).

Figure 1. Schematic diagram showing lateral milling and the four types of mills used in this study,

RESULTS AND DISCUSSION

The cutting (milling) forces for Co-Cr-Mo alloy were generally higher at lower cutting speed than those required at higher cutting speed although the Type B (S21N) mill required approximately 60% lower force than the other three types of mills at 10,000 rpm

(Fig.2a). At cutting speeds above 15,000 rpm the forces were comparable, i.e. around 1N, with much less force required for one mill at 35,000 rpm. For Ti-Al-Nb, the cutting (milling) forces ranged from 0.5 to 2 N for all mills used (Fig. 2b).

Figure 2. Cutting force required during lateral milling at constant feed rate and a range of mill rotation speeds.

The appearance of the machined surfaces showed significant variations related to the extent to which metal chips retained in the mill flutes had frictionally re-welded onto the surfaces behind the mill. This was considered to be partly due to the high temperature of the machining process resulting from the absence of liquid coolant but was also associated with tool wear.

Figure 3. SEM images of machined surfaces.

CONCLUSIONS

The force required for high speed micro-milling of a cobalt alloy in the absence of coolant was relatively insensitive to speed and mill configuration at mill rotational speeds between 15,000 rpm and 25,000 rpm. For this alloy, relative cutting forces were affected by mill configuration at lower and higher rotational speeds. On a titanium alloy, cutting forces were relatively low at all speeds, with little influence of mill configuration at higher speeds. Metal chip re-welding affected the workpiece surface finish of both alloys.

ORAL PRESENTATIONS

The drive for simplicity in delivering cells to the clinic - clever cells and dumb scaffolds

Sheila MacNeil¹

¹Department of Materials Science & Engineering, Kroto Research Institute, University of Sheffield, UK
s.macneil@sheffield.ac.uk

INTRODUCTION

One of the challenges for the world of biomaterials and tissue engineering has been to what extent scaffolds need to be complex and mimic human physiology such as containing the collagenous extracellular matrix signalling motifs which promote cell binding and differentiation *in vivo*. Can synthetic scaffolds ever been good enough for tissue engineering purposes? How much complexity is necessary for clinical efficacy? Should we stick with natural decellularised scaffolds (for example for 3D tissue reconstruction for skin and oral mucosa) or can we make an altogether simpler synthetic alternative? There are pros and cons in working with natural tissues in that they can retain the native architecture, particularly basement membrane which helps give cells instructions. There are pluses in working with very simple synthetic scaffolds in terms of controllability, ease of sterilisation and regulatory issues. My group has been making tissue engineered materials for clinical use since early 1992 and has developed a good understanding of the pros and cons of both.

EXPERIMENTAL METHODS

We have delivered 3D tissue engineered skin to the clinic based on human donor skin which has been de-epithelialised and decellularised and then reconstituted with the patient's own keratinocytes and fibroblasts [1]. This methodology has also been used to deliver tissue engineered buccal mucosa to the clinic [2]. We have also developed simple 2D and 3D carriers for delivering keratinocytes to patients with extensive full thickness burns (developed as the product Myskin™) [3]. More recently this method has also been used to deliver other cells [4,5]. We have also developed 3D biodegradable scaffolds made of PLGA for delivering corneal limbal epithelial cells to the cornea in cases of limbal stem cell loss [6].

RESULTS AND DISCUSSION

Both natural materials and synthetic materials can deliver clinical benefit and our findings are that if one combines the right combination of cells in a very simple scaffold then the cells can achieve the appropriate phenotype *in vitro* for transplantation even with a "dumb" scaffold.

CONCLUSION

In developing cells and scaffolds to go to the clinic, it is always worth asking what is the least complex system that will work as the simpler the system, the less the problems in translating this to the clinic and in making it broadly applicable.

INTRODUCTION

The ability to manipulate cell behaviour is a cornerstone of cell biology. Since its inception, the driving paradigm in this discipline has been to control cell physiology and phenotype through the application of a range of “drug-like” compounds such as small molecules, hormones and growth factors.

In contrast, there is now compelling evidence that cellular phenotype is dependent on the extracellular surface topography and the spatial location of chemical signals at the sub-micron scale.¹⁻⁴ The use of designer micro- and nanofabricated surfaces to control cell behaviour therefore offers an intriguing alternative to the conventional approaches in cell biology.

However, research in this area has until recently been hampered by the difficulty in fabricating such nanostructured surfaces suitable for exploratory cell biology. The vast majority of standard nanofabrication methods are derived from the microelectronics industry, and are poorly suited for the generation of nanoscale patterns of relatively fragile biomolecules in sufficiently large areas for routine cell culture.

As an alternative, we and others have started to apply scanning probe nanolithography methods derived from atomic force microscopy (AFM) such as dip-pen nanolithography (DPN) and polymer pen lithography (PPL) for the fabrication of micro- and nanoscale biomolecular arrays.^{2, 5, 6} These methods are compatible with biomolecules, operate under ambient conditions and enable nanopatterning over large areas (cm²).

Here, we describe some of our work related to the development of methods for the fabrication of large-area biomolecular arrays, down to the resolution of a single protein molecule; and the application of such arrays to manipulating mesenchymal stem cell (MSC) differentiation.

EXPERIMENTAL METHODS

For the control of MSC differentiation, full experimental procedures have been reported elsewhere.² Briefly, PPL was used to deposit features of 16-mercaptohexadecanoic acid on gold surfaces in a range of spot feature sizes from 300–1200 nm in diameter. These features acted as a template for the adsorption of fibronectin, upon which the MSCs were cultured. The cells were analysed by a combination of immunofluorescence microscopy, quantitative RT-PCR and Western blotting of the proteins of interest.

For the single molecule protein arrays, the arrays of gold nanoparticles were fabricated by scanning probe block copolymer lithography (SPBCL), where were then surface treated according to previously reported procedures.⁵ These nanoparticles served as the template for the attachment of individual protein molecules. The protein activity was analysed by a colorimetric assays, or through the selective binding of nanoparticle labels and subsequent transmission electron microscopy.

RESULTS AND DISCUSSION

Using the large arrays of fibronectin printed by PPL, it was found that the MSCs were cultured on fibronectin patterns with a feature size of 300 nm a pitch of 1200 nm demonstrated a statistically significant increase in the expression levels of the osteogenic markers even in the absence of the standard osteogenic culture media.

In the case of SPBCL templating of proteins, it was found that when the gold nanoparticles were similar in size to the target protein (~ 4 nm for streptavidin, ~ 10 nm for antibodies), on average only one protein molecule was attached to each individual nanoparticle on the array. Furthermore, activity assays and electron microscopy analysis of the labelled proteins showed that the attached protein retain their biological activity.

Photochemical Functionalisation and Patterning of Diamond-Like-Carbon for Electronic Neural Interfaces

James Dugan and Frederik Claeysens

Department of Materials Science and Engineering, Kroto Research Institute, The University of Sheffield, UK.

J.Dugan@sheffield.ac.uk

INTRODUCTION

The development of electrodes for direct interface with the brain has the potential to greatly improve prostheses to aid victims of spinal injury or similar disablement. However, the development of such electrodes relies on careful engineering of the biological-electronic interface with control of scarring, cell phenotype and tissue organisation. Diamond-like-carbon (DLC) may be an ideal material for coating electrodes as it has flexible electrical properties, it is extremely stable *in vivo* and is already used as a coating for orthopaedic implants¹. Chemical modification is essential, however, to control and promote adhesion, differentiation and organisation of neurons and glia.

EXPERIMENTAL METHODS

DLC was coated on silicon by chemical vapour deposition. The surface chemistry of the DLC was modified by atom transfer radical polymerization (ATRP) in order to produce PEG-coated non-cell-adhesive surfaces. The surfaces were then further modified photochemically with charged monomers in order to promote cell adhesion and neuronal differentiation in a controlled fashion. Several techniques were also employed for surface patterning including the use of shadow masks, direct-write photopolymerisation of charged monomers and pulsed laser ablation of non-adhesive polymer coatings.

The modified DLC surfaces were characterised by AFM, XPS and Raman spectroscopy and for protein adsorption by immunofluorescence. The potential for use in neural-electronic interfaces was explored by culture and differentiation of primary neural progenitors.

RESULTS AND DISCUSSION

Freshly hydrogenated DLC and ATRP PEG-functionalized DLC were found to be non-adhesive to cells. By modification with surface initiated polyacrylic acid (PAA), hydrophilicity and cell adhesion were promoted. Neural progenitors adhered to the modified surfaces and a multipotent phenotype was maintained until withdrawal of growth factors. Spontaneous differentiation occurred on the modified surfaces with both neuronal and glial differentiation observed. Patterned tracks were prepared by masked polymerisation of charged monomers and promoted spatial organisation of neuronal cells. Spatial control of

cell adhesion was also achieved by pulsed laser ablation of ATRP PEG surfaces to reveal adhesive regions that supported protein adsorption and cell adhesion.

Fig. 1. Immunofluorescence micrographs of neuroprogenitors before (a, b) and after (c, d) spontaneous differentiation on glass (a) and polyacrylic acid coated surfaces (b, c, d). Cells were stained for nestin (red), β III-tubulin (green, c) and GFAP (green, d). Scale bars in a and b are 150 μ m. Scale bars in c and d are 80 μ m.

CONCLUSION

The surface chemistry of DLC was modified and patterned by facile photochemical methods. Such approaches allow for the tuning of biological properties and the rational design of the electrode-brain interface. Further studies on the differentiation of stem cells and the development of controlled patterning protocols will be carried out.

Impact Testing of Skin: Overcoming the Stratum Corneum Barrier for Microneedle Application

Kikelomo Moronkeji^{1*}, Simon Todd², Ahmed Elsheikh¹ and Riaz Akhtar¹

^{1*}School of Engineering, University of Liverpool, UK, K.Moronkeji@liverpool.ac.uk

²Renephra Ltd, Manchester, UK

INTRODUCTION

Due to limitations with conventional hypodermic needles, microneedles have been developed over a number of years to painlessly deliver drugs and vaccines through the skin¹. Microneedles are sub-millimetre arrays typically fabricated from polymers or metal which aim to penetrate the stratum corneum and directly access the underlying epidermis². However, it remains a major challenge to reproducibly penetrate the stratum corneum due to its inherent elasticity and other factors that affect the mechanical properties of the stratum corneum such as patient age. Previous studies have suggested that application speed and force influence penetration of stratum corneum with microneedles³, however there is little quantitative data in the literature. This study aimed to quantify the optimal insertion speed and force of Polyether ether ketone (PEEK) oblique microneedle arrays into skin.

EXPERIMENTAL METHODS

9 x 9 arrays of PEEK microneedles (Fig. 1) were utilised to penetrate neonatal porcine skin in vitro. Neonatal porcine skin has a comparable mechanical properties to human skin⁴. A dropped weight impact testing rig was developed to allow microneedle application to be varied as a function of velocities in excess of 2 m/s, with the total load of the drop mass measured by a force transducer being 0.4 N.

Fig. 1 SEM image of PEEK oblique microneedle arrays

RESULTS AND DISCUSSION

Impact speed significantly influenced the quality and consistency of microneedle penetration. Methylene blue and histological staining (H&E) were used to determine penetration. Successful penetration of the stratum corneum occurred at 3–5 m/s (Figs. 2 and 3), with no evidence of penetration at lower speeds – this is 1000 times⁵ the penetration speed required for hypodermic needles. The histology images at different regions on a single sample of skin show the breached profile follows the microneedle outline (Fig. 3) and the size of the tear in the epidermis was found to correlate with the size of the microneedle. Further, a series of gelatine gels (67%, 80%, 88% and 96% water content) were used to act as an underlying substrate for skin. The speed at

which successful penetration occurred significantly decreased at higher water contents.

Fig. 2 Velocity-time plot of impact test on skin (back region) at 5 m/s and 0.4 N

Fig. 3 Histology images of microneedle breach of the epidermis

CONCLUSIONS

Our findings suggests that for successful penetration of the stratum corneum far higher velocities are required than associated with conventional hypodermic needles and reduced penetration speed with increasing gel water content.

Exploring the Cell-Nanoneedle Interface

Ciro Chiappini^{1,3}, Jonathan O. Martinez², Enrica De Rosa², Paola Campagnolo¹, Ennio Tasciotti², Molly M. Stevens^{1,3*}

¹Department of Materials, Imperial College London, UK

²Department of Nanomedicine, Methodist Houston Research Institute, USA

³Department of Bioengineering and Institute of Biomedical Engineering, Imperial College London, UK
c.chiappini@imperial.ac.uk

INTRODUCTION

Nanoneedles are attracting increasing interest as a facile, high-throughput, minimally invasive strategy for intracellular investigation due to their low-cost, versatility and ease of use. Nanoneedles *in-vitro* have investigated the propagation of action potentials within excitable cells¹, as well as mediated the intracellular delivery of membrane-impermeant biomolecules such as peptides and nucleic acids². Despite these initial successes at probing the intracellular compartment, little is known of how nanoneedles interface with cells. Conflicting evidence exists as to whether the nanoneedles effectively cross the plasmalemma or they simply induce an increase in its permeability^{2,3}. In this study we aim to investigate the ability of porous silicon nanoneedles to cross the plasma membrane by observing their ability to deliver nanoparticles to the cytosol. At the same time we investigate the evolution of the cell-nanoneedle interface over time.

EXPERIMENTAL METHODS

Nanoneedles are fabricated combining photolithography, metal assisted chemical etching and reactive ion etching of a single crystal silicon substrate. The resulting nanoneedles are 55% porous with a pore size in the range of 15 nm. The nanoneedles are loaded with hydrophilic quantum dots from solution and interfaced with cells either by seeding HeLa cells over the nanoneedles or by pressing the nanoneedles over HeLa cells in culture. The samples are analysed by confocal microscopy and by dual beam focussed ion beam scanning electron microscopy.

RESULTS AND DISCUSSION

We have developed an array vertically aligned biodegradable nanoneedles that originate from our recent systematic investigation of metal assisted chemical etch. The nanoneedles were vertically supported over a silicon substrate, had a tip diameter smaller than 100 nm, 15 nm pores with 55% porosity, and a length of 3 microns (Figure 1). When seeding cells over the nanoneedles we observed that the needles had penetrated across the cell membrane within 1h (Figure 2). Up until 8h following seeding the cells descended along the nanoneedles, partly internalizing them. For the entire time, the needles localized within the cell cytosol but did not cross the nuclear envelope. The nanoneedles were able to deliver cell-impermeant quantum dots directly to the cytosol within 30 minutes from interfacing. The interfacing with nanoneedles did not induce any change in cell viability or proliferation, compared to controls grown on flat silicon substrates.

Figure 1 Scanning electron micrograph showing a vertical array of porous silicon nanoneedles with less than 100 nm tip and 3 μm length. Scale bar 2 μm.

The nanoneedles fully degraded both inside and outside the cell within a 27h timeframe, as supported by SEM and inductively coupled plasma – atomic emission spectroscopy.

Figure 2 Nanoneedles penetrate the cell cytosol over time. Left FIB-SEM image showing nanoneedles penetrating within a cell 1h following seeding. Right, FIB-SEM imaging showing a nanoneedle penetrating within a cell 8h following seeding, inducing deformation of the cell nucleus. Scale bar 2 μm.

CONCLUSION

We demonstrated the fabrication of biodegradable nanoneedles that can rapidly cross the cell membrane to deliver cell-impermeant nanoparticles to the cytosol with minimal inherent toxicity for the cell. The nanoneedles degrade progressively over the course of 72 h.

Strategies to Enhance the Cellular Response to Bioactive Surfaces

L. Rutledge¹, L. Randolph², I. Mutreja¹, B. Meenan,¹ A. Boyd¹

¹NIBEC, University of Ulster, United Kingdom, Rutledge-L1@email.ulster.ac.uk, ²Grenoble IPN, France.

INTRODUCTION

According to the National Joint Registry^[1], since 2011 there has been a rise of 7.4% in the number of hip and knee total joint replacements procedures carried out within the U.K. The current method of carrying out these procedures using hydroxyapatite (HA) are not ideal, as the HA coating is often prone to deficiency, resulting in unacceptably high revision rates for younger patients. In order to address this, and meet demand, this project seeks to renew impetus for the development of multifunctional, HA surfaces, e.g. Strontium or Silicon doped HA, which can augment the chemical and topographical surface properties of the orthopaedic biomaterial, making a more favourable physiological environment, which in turn will drive biological response and induce more rapid osteointegration. It is envisioned that this strategy will enhance the bone-biomaterial interface, improving the orthopaedic implant stability and long term survival, therefore enhancing the clinical outcome for the patient.

EXPERIMENTAL METHODS

A range of Calcium Phosphate (Ca-P) coatings were deposited onto medical grade titanium alloys (Ti-6Al-4V) using radio frequency (RF) Magnetron Sputtering. Coatings were produced from both pure HA and Sr doped HA (Sr-HA) starting powders (5-13% wt/wt). The starting target materials and the resultant coatings (as-received, thermally processed) were characterised using analytical techniques including X-ray diffraction (XRD), Fourier Transform Infrared (FTIR), Atomic Force Microscopy (AFM) and X-ray photoelectron spectroscopy (XPS). *In vitro* methods (PicoGreen® Assay) were used to look at the early osteoblast in response to the different coatings.

RESULTS AND DISCUSSION

The XRD and FTIR results show that the purity, crystallinity and stoichiometry of HA and Sr-HA (5% and 13%) starting powders were as expected, with the XRD data confirming that the HA materials conformed to the International Centre for Diffraction Data (ICDD) File (09-0432) for pure HA. FTIR and XRD results for the as-deposited HA and Sr-HA derived coatings indicate that they are amorphous and dehydroxylated. Upon annealing to 500°C, the FTIR data highlights that the HA coatings had all the expected OH⁻ and PO₄³⁻ bands, with a high degree of hydroxylation. In comparison, the Sr-HA coatings were dehydroxylated even after annealing, with dehydroxylation increasing with increasing Sr content. The XRD results for these materials indicated that after annealing all the coatings had well defined crystalline peaks, (Fig. 1.) However, the diffraction peaks shifted to lower 2θ values with increasing Sr content. XPS data (Fig.2) shows that when Sr is added to HA, Sr peaks appeared at 275eV (Sr3p) and 134eV (Sr3d).

Fig. 1. XRD results (a) HA Coating, (b) 5% Sr-HA coating and (c) 13% Sr-HA coating

Fig. 2. XPS data showing 5% HA-Sr coating

Fig. 3. AFM results for (a) titanium coated substrate, (b) HA coating, (c) 5% Sr-HA coating and (d) 13% Sr-HA coating

No Sr peaks were observed in the pure HA coatings. The XPS results highlighted that the Ca/P ratio decreased from 1.79 for HA to around 1.5 for the Sr-HA surfaces. Also, the Atomic Concentration (%) of Sr in the coatings increases from 1.21% to 3.47% for the 5% and 13% Sr-HA derived materials, respectively. The AFM data (Fig. 3) highlighted that the surface roughness (R_a) of the coatings increased with increasing Sr content. In particular, the R_a increases from 11.8 ± 1.6 nm to 16.2 ± 1.6 nm for the 5% and 13% derived Sr-HA coatings, respectively. All of these results indicate that increasing Sr content in the coatings was due to the Sr ions substituting for the Ca(II) ions causing significant disruption of the lattice. This is corroborated through the greater surface feature irregularity seen in the Sr-HA samples. *In vitro* studies show that the Sr-doped material show enhanced levels of cell attachment up to 72 hours.

CONCLUSION

RF Magnetron Sputtering provides a route to adding Sr to Ca-P coatings with process control. The results show that the coatings produced are similar to HA and are modified accordingly with the addition of different levels of Sr. The preliminary *in vitro* studies indicate that the Sr doped samples show enhanced levels of cell attachment at early time-points (24 and 72 hours), highlighting the potential benefit of adding Sr into such HA coatings. These results are preliminary and need to be expanded. In particular, understanding the potential of these surfaces to promote the differentiation of Mesenchymal Stem Cells, would be important as it would provide a route to developing enhanced surfaces, improving the clinical outcome for patients. Furthermore, it would be useful to study the effects of multi-ion doped coatings in this regard, as opposed to just single ion-doped materials, as further enhancements in surface properties may be possible.

The Effect of Extrinsic Tooth Bleaching Agents on Restorative Dental Materials: A Review

Paul Hatton

Bioengineering & Health Technologies Research Group, School of Clinical Dentistry, University of Sheffield, Claremont Crescent, Sheffield S10 1EX, UK. paul.hatton@sheffield.ac.uk

INTRODUCTION

Tooth bleaching has increased markedly in popularity in the past two decades, coupled to a rapid increase in the availability of both in-office and over-the-counter products that claim to improve the whiteness of teeth. The vast majority of bleaching systems are based on the delivery of hydrogen peroxide, a powerful oxidising agent that is known to be capable of causing tissue damage. Numerous studies of the potential effects of hydrogen peroxide on tissues have therefore been reported to date [1,2]. Effects on dental materials have not been investigated as thoroughly, despite the potential for hydrogen peroxide to cause damage. The aim of this paper was therefore to review data related to the interaction of hydrogen peroxide with restorative dental materials, and determine whether or not this interaction represents a risk to health. This paper will include consideration of experimental studies conducted in Sheffield.

EXPERIMENTAL METHODS

In experimental work, commercial spherical dental amalgams (Tytin® or Sybralloy®, Kerr, UK) were investigated in the form of discs (10 mm x 2 mm) that were exposed to either carbamide peroxide (a hydrogen peroxide generating system), hydrogen peroxide directly, or a range of control materials including distilled water, for 24 h at 37 °C. Ion release was determined using inductively coupled plasma-mass spectrometry (ICP-MS). Where reported, surface roughness was determined using a Talysurf (Mitutoyo Corporation, Japan), while specimen surfaces were investigated using scanning electron microscopy [3,4]. The data from these studies and other work conducted in Sheffield was reviewed alongside other relevant scientific publications.

RESULTS AND DISCUSSION

Several studies reported that hydrogen peroxide treatments were capable of increasing metal ion release from dental amalgam in a dose dependent manner. For example, Table 1 shows that mercury release from Tytin® was increased significantly by two different

[Hydrogen Peroxide] % (w/v)	Mean [Hg] (µg/l)	± Standard Deviation
0	3	1
3	316	75
30	1428	883

Table 1. Release of mercury (Hg) from Tytin® amalgam discs after 24 h exposure to different concentrations of hydrogen peroxide. Adapted from Al-Salehi *et al.* 2007 [3].

concentrations of hydrogen peroxide. No significant change in roughness was associated with these treatments [3]. The evidence that tooth bleaching systems interact with restorative materials is now compelling, and it is recommended here that clinicians protect restorations during these interventions in the same way that they protect soft tissues. With respect to over-the-counter products, there is clearly an even greater risk that consumers will not protect either soft tissues or materials. Despite these concerns, injuries or adverse health effects related to hydrogen peroxide have not been reported widely [5]. In comparison, clinical studies claimed that exposure to relatively high concentrations of carbamide peroxide (up to 16%, the equivalent of 5.3% hydrogen peroxide) was relatively safe and effective [6,7].

CONCLUSION

It was concluded that hydrogen peroxide, whether applied directly or generated by carbamide peroxide, interacted with restorative dental materials. These interactions were concentration dependent, they were potentially damaging to the biomaterial itself (primarily at the surface), and some of the events were potentially harmful to the health of the patient. Further research is undoubtedly needed to inform clinicians, regulators and the public so that informed decisions may be made related to the licensing and use of tooth bleaching systems. Given the increased availability of commercial systems, including chemicals of uncertain provenance than may be purchased easily via the Internet for home use, the need for further research is pressing.

f.decogan@bham.ac.uk

INTRODUCTION

The current management of microbial infection in injured tissues is by the systemic administration of antibiotic drugs. These are designed to eliminate pathogens while leaving the patient unharmed. This method is of limited efficacy as systemic antibiotics are not targeted to the site of infection and will often have poor penetration to areas around wounds and implants. The widespread use of prophylactic antibiotics has also led to increasing microbial resistance.

Naturally occurring defence proteins (Defensins) are found in all tissues and comprise a major part of the innate immune system.¹ These proteins are active against a wide range of microbes, fungi and viruses, are of great research interest as they have high antibacterial efficiency and are less likely to promote bacterial resistance. Unlike standard antibiotics, the Defensins target the microbial cell membrane, so, microbes must redesign their cell membrane to acquire resistance.

We are developing synthetic Defensin-related peptides as broad spectrum antibiotic surface coatings for a range of uses. The use of Defensins as equipment and device coatings will prevent infection of wound sites thereby protecting patients during their treatment pathway.

EXPERIMENTAL METHODS

Defensin-related peptides were synthesised using standard solid phase peptide synthesis and Fmoc chemistry. The final product was purified by HPLC and characterised by mass spectrometry. Peptides were attached to hydroxyapatite and titanium surfaces by electrostatic interaction by incubating the peptide with the material for 30 minutes at room temperature.

For covalent attachment hydroxyapatite surfaces were functionalised to incorporate thiol groups onto the surface of the titanium. Antimicrobial peptides were then functionalised onto the surface using maleimide crosslinkers. Titanium surfaces were functionalised by nitriding the titanium to give free amine groups on the surface. The antimicrobial peptides were then grafted to the surface using peptide coupling.

The antimicrobial activity of the synthetic Defensins was evaluated using the Antimicrobial Minimum Inhibitory Concentration (MIC) tests carried out using standard lab strains of *E. Coli*, *P. Aeruginosa* and *S. Aureaus*. The peptides were also tested against clinical isolates from eyes, general wounds, burn wounds and bone infections. The antimicrobial activity of the peptides while bound to the hydroxyapatite and titanium

surface by incubating Defensin coated blocks in bacteria cultures for 24 hours and monitoring solution phase bacteria growth plus biofilm and surface growth on the material.

RESULTS AND DISCUSSION

Two peptide sequences, RRIYGRGYIRR designed to mimic α defensins and RRRRRR-GALAG-RRRRRR-GALAG designed to mimic β defensins, were both shown to have broad spectrum antibacterial activity with MIC values of 3.9 μ g/mL – 1.25mg/mL. The peptides were similarly active when covalently and electrostatically bound to the titanium surface, prevented biofilm formation and sterilised the surrounding solution (Figure).

Figure Growth of MRSA on untreated and peptide treated surfaces.

CONCLUSION

We have designed and synthesised active antimicrobial peptides that can be electrostatically and covalently bound onto surfaces. We have shown that they are active in solution and when surface bound, preventing biofilm formation. This makes the peptide coatings a desirable surface modification for biomaterial and tissue engineered surfaces to prevent patient infections.

Development of decellularised conjunctiva for ocular surface reconstruction

Shivani Kasbekar¹, Rosalind Stewart¹, Stephen Kaye¹, Rachel Williams¹, and Paul Rooney²

¹Department of Eye and Vision Science, University of Liverpool, UK

^{2*}Research and Development, NHS Blood and Transplant, Liverpool, UK, s.kasbekar@liverpool.ac.uk

INTRODUCTION

A key advantage of decellularised tissue over allografts is that it is non-immunogenic and may provide an ideal scaffold for recellularisation with autologous cells. Conjunctival grafts are required to treat a range of ocular surface diseases and decellularised conjunctiva may prove to be a useful biomaterial in these applications. This study aimed developed a decellularisation process for conjunctival tissue and characterise its properties.

EXPERIMENTAL METHODS

Decellularisation was undertaken using a protocol described for dermis adapted by changing the detergent buffer in which varying concentrations of Sodium dodecyl sulfate (SDS) were used.^[1] DNA was quantified through isolation (DNAeasy, Invitrogen, UK) and fluorometric quantification using PicoGreen (Invitrogen, UK). In addition, a quantitative collagen denaturation assay was performed, histology with DAPI, H&E and Van Gieson's, and contact cytotoxicity by Giemsa staining using a conjunctival cell line (HCjE-Gi) and primary human fibroblasts. Bulbar conjunctiva from four human cadaveric donors was used for analysis in this study. SPSS was used to analyse data; ANOVA and student-t tests utilised where appropriate.

RESULTS AND DISCUSSION

Decellularisation of conjunctiva was achieved using an adapted process for decellularisation of dermis and was successful at all SDS concentrations over 0.05%, $p < 0.0001$ (figure 1). This was reproducible in triplicates from three further donors ($p < 0.0001$). Conjunctival epithelial cells and human fibroblasts were found growing adjacent to and within the decellularised tissue on contact cytotoxicity testing (figure 2). There was no evidence of significant collagen denaturation as a result of decellularisation (student's t test $p = 0.14$, $p = 0.42$, $p = 0.84$ for quantified hydroxyproline in cellular compared with decellularised tissue using tissues from 3 donors in triplicate).

Table 1

Samples	Number of tissue samples	Mean DNA content ng/mg (+/- 2SD)
Cellular control	3	42.3 (7.4)
Donor 1 decellularised	3	0.47 (0.14)
Donor 2 decellularised	3	0.36 (0.08)
Donor 3 decellularised	3	0.33 (0.07)

This table displays DNA ng/mg of conjunctival tissues from three separate donors, with triplicates analysed in each group. ANOVA $p < 0.0001$.

Figure 1

ANOVA $P < 0.0001$, DNA content $< 99\%$ decellularised versus cellular tissue (triplicate samples in each group); error bars display $\pm 2SD$

Figure 2

— 200µm Decellularised tissues are on the left hand side of both pictures a)HCjE-Gi cells b)primary human fibroblasts

The results of this study demonstrate that decellularisation of human conjunctiva can be effectively achieved using a modified protocol for dermis using an SDS concentration of 0.05% and is reproducible in several donors conjunctival tissue. The resulting tissues are not cytotoxic, the collagen is not significantly denatured and the tissue ultrastructure (examined by histology) is preserved whilst cellular material appears removed.

CONCLUSION

Decellularised human conjunctiva can be derived using our protocols in which the tissue architecture including collagen is preserved. This may prove to be an ideal tissue derived scaffold for the expansion of conjunctival epithelium to produce novel grafts for ocular surface reconstruction.

INTRODUCTION

Collagen is the most abundant building block of connective tissues¹ and has been widely applied for the design of biomimetic materials, *e.g.* for wound dressings and scaffolds for regenerative medicine. However, collagen materials often exhibit restricted material properties, *e.g.* high swelling and poor elasticity, in physiological conditions, resulting in challenging customisation of mechanical properties.² To address this challenge, an interdisciplinary approach was chosen in which crosslinking chemistry was used for the direct build-up of triple-helical collagen hydrogels.³ Together with molecular investigations on the network architecture and protein organisation, hydrated mechanical properties were closely characterised from the nano- up to the macro-scale.

EXPERIMENTAL METHODS

In-house isolated type I collagen was reacted with vinyl monomers of varied backbone rigidity and characterised via 2,4,6-Trinitrobenzene Sulfonic Acid (TNBS) colorimetric assay and ¹H-NMR. Full gel formation was accomplished following UV activation (Spectroline, 346 nm, 9 mW/cm²) of collagen precursors. Hydrogels were imaged and mechanically tested via AFM under ultrapure water (MFP-3D, Asylum Research Corp). A V-shaped silicon nitride cantilever (Hydra6V series, AppNano, Santa Clara, USA) was used with a spring constant ~0.3 N·m⁻¹ and tip radius of 15 nm. Elastic modulus was extracted from arrays of nanoindentation up to a load of 20 nN using Hertzian based theory, while imaging of the gels was performed using either contact or tapping mode. Together with AFM, bulk compression measurements were carried out on hydrogel discs (ø 0.8 cm) with a compression rate of 3 mm·min⁻¹ (Instron 5544 UTM).

RESULTS AND DISCUSSION

All hydrogels exhibited elastic moduli in the range of 10-400 kPa, whilst being highly swollen in the test conditions (water uptake > 700 wt.%). Variations in network architecture at the molecular level (Figure 1 A) dictated the mechanical behaviour of the hydrogels at both nano- and macroscopic scales, with the molecular stiffness of employed cross-linkers playing a major role. AFM elastic moduli correlated with the results obtained with bulk compression measurements. Hydrogels described nearly-elastic behaviour during the force-volume AFM measurements; minimal hysteresis (~attojoule) was observed between the approach and

retraction curves (Figure 1 B), likely due to the presence of the covalent network at the molecular level. AFM imaging elucidated the protein organisation of functionalised collagen molecules at the gel surface, depending on the cross-linker employed.

Figure 1. (A): Comparison of AFM elastic moduli in hydrogels functionalised with either glycidyl methacrylate (GMA) or 4-vinylbenzyl chloride (4VBC) with varied degree of collagen functionalisation (*F*). (B): Exemplary AFM force-indentation curve on collagen hydrogel.

CONCLUSION

Tunable collagen hydrogels were successfully synthesised from photo-active precursors and investigated from the molecular to the macroscopic scale. Remarkable swelling ratio and elastic modulus were observed in fully hydrated samples, depending on the collagen functionalisation introduced at the molecular level. AFM was successfully applied in hydrated conditions and yielded elastic moduli values comparable to the bulk values, whilst giving information on the fibril forming ability of functionalised collagen. In light of their remarkable swelling and mechanical properties, these collagen hydrogels are highly relevant to applications in cell biology and biotechnology as well as having great potential for clinical applications in wound care and regenerative medicine.

Mechanical and Cytotoxic Evaluation of a Novel Hydrogel with Potential Application as a Corneal Bandage

Andrew Gallagher^{1,2}, Don Wellings¹ and Rachel Williams²

¹Spheritech Ltd, Runcorn, UK.

²Department of Eye and Vision Science, University of Liverpool, UK. andy@liverpool.ac.uk

INTRODUCTION

A novel hydrogel biomaterial developed in-house at Spheritech Ltd (Proliferate™ Gel) was identified as having desirable properties associated with corneal bandages. These include; a high water content, excellent transparency and a modifiable surface chemistry. This study aimed to modify the mechanical properties of Proliferate™ Gel to achieve comparable properties to established contact lens materials. Some of these materials were used as a benchmark for four different Proliferate™ Gel polymers.

The cytocompatibility of Proliferate™ Gel towards a human corneal epithelium cell line (HCE-T) was also established. This study lays the framework for a more extensive investigation of Proliferate™ Gel as a corneal bandage.

EXPERIMENTAL METHODS

The hydrogel material used in this study was composed of poly-L-lysine and suberic acid using a carbodiimide-NHS cross-linking technique. Alterations in the level of cross-linking and the density of the polymer produced the different variants of Proliferate™ Gel. Percentage water content of Proliferate™ Gel was determined following ISO standard: 18369:4:2006. Mechanical properties of the variants were measured using a Linkam TST350 tensile tester. Stress, strain and Young's modulus were determined. The cytotoxicity of Proliferate Gel towards the HCE-T cell line was determined using a CCK-8 cytotoxicity kit following the manufacturer's protocol. Cellular morphology was imaged using a NIKON Eclipse TI-E inverted microscope.

RESULTS AND DISCUSSION

Material	% H ₂ O content	Young's Modulus (MPa)
HEMA/MAA	70%	0.77 (+/- 0.11)
Proliferate™ Gel Su6013 (60% cross-linked, 0.077g/ml polymer density)	67%	0.73 (+/- 0.12)
Proliferate™ Gel Su6014 (60% cross-linked, 0.071g/ml polymer density)	69%	0.50 (+/- 0.11)
VP/MMA	70%	0.49 (+/- 0.09)
Proliferate™ Gel Su6515 (65% cross-linked, 0.066g/ml polymer density)	71%	0.46 (+/- 0.08)
HEMA/VP	55%	0.36 (+/- 0.07)
Proliferate™ Gel Su6015 (60% cross-linked, 0.066g/ml polymer density)	70%	0.31 (+/- 0.04)

Table 1: Young's modulus data for common contact lens material compared to Proliferate™ Gel variants¹.

Proliferate™ Gel variants have the highest water content but still retain mechanical properties within the range of the commercial contact lens materials (table 1). In fact whilst the water content

of all the Proliferate™ Gel samples remain constant the Young's modulus values cover the range of those included in table 1.

Figure 1: Growth Curve for HCE-T Cells Cultured in Standard Media Pre-incubated with Proliferate™ Gel Su6014 in Comparison to Cells Cultured in Standard Media without Pre-incubation

The 8 day growth curve of HCE-T cells cultured in standard media compared to those cultured in media pre-incubated with Proliferate™ Gel Su6014 demonstrated there was no significant difference between the cell growth which suggests that Proliferate™ Gel Su6014 does not affect HCE-T cell survival and proliferation compared to the control (figure 1). This data suggests that any leachables from proliferate™ Gel Su6014 are non-cytotoxic towards the HCE-T cell line.

When the HCE-T cells were seeded in direct contact with the hydrogel very few cells attached to the surface and those that remained retained a

spherical morphology after 48 h (figure 2). Cells cultured on tissue culture plastic directly underneath Proliferate™ Gel Su6014 appear to have a typical cobblestone shape after 48 h as expected for this cell type (figure 3). These observations suggest that Proliferate™ Gel Su6014 is highly hydrophilic which inhibits cell attachment but is

non-cytotoxic to the corneal epithelium. Further evidence of this will be investigated in the near future.

CONCLUSION

This study has found that Proliferate™ Gel can be tailored to have mechanical properties similar to commercial contact lens materials. This coupled with the cytocompatibility of the material towards HCE-T cells merits further investigation of Proliferate™ Gel as a potential corneal bandage material.

Linking antimicrobial peptides with the surface of metallic implants

Zuzanna Trzcińska^{1*}, Anna Peacock² and Artemis Stamboulis¹

¹ Biomaterials Group, School of Metallurgy and Materials, University of Birmingham, United Kingdom,
zxt166@bham.ac.uk

² School of Chemistry, University of Birmingham, Edgbaston, Birmingham, United Kingdom

INTRODUCTION

Infections associated with bone replacement surgeries are one of the main causes of the early rejection of a prosthetic implant. The constant emergence of the antibiotic resistant bacteria strains calls for the use of different bactericidal solutions. Antimicrobial peptides (AMPs) have emerged as antibiotic substitute candidates.¹ AMPs are a part of innate immunity of all organisms and bacteria have not developed effective resistance towards them. Linking AMPs with the implant surface could lead to decrease of the infection related implant rejections.

Currently used implant materials do not allow for the stable conjugation of the antimicrobial biomolecules without use of harsh chemicals.² Peptide aptamers² or adhesive polymeric³ coatings formed by the dip-coating method could provide a surface chemistry functionalization which would link inorganic surfaces with AMPs.

EXPERIMENTAL METHODS

Ti6Al4V plates were grinded with SiC 400 grinding paper, followed by ultrasonic cleaning in acetone and deionised water.

AMPs and AMPs sequences conjugated with peptide aptamers (AMP-pas) were synthesized by Solid Phase Peptide Synthesis and were labelled with carboxyfluorescein dye (FAM). The purities and molecular weights of synthesized products were confirmed by High Pressure Liquid Chromatography (HPLC) and Mass Spectrometry (MS), respectively. AMP-pas were coated on the surface of Ti6Al4V via the dip-coating method and were used the same day.

The coating of Ti6Al4V plates with the adhesive polymer took place simultaneously with its polymerisation via dip-coating. AMPs were then conjugated with the polymeric thin layer.

Scanning Electron Microscopy (SEM) was used to image the surface of coated Ti6Al4V plates and Atomic Force Microscopy was used to compare the structure of the coatings.

Fluorescence Microscopy was performed at 495 nm to visualise and compare the amount of AMPs on the surface. The comparison was done based on the fluorescence intensities of the coated surface.

The stabilities of the AMPs on the surface were performed by immersion of the coated plates in simulated body fluid (SBF). Then they were analysed via fluorescence studies in terms of fluorescence intensity change, where the decrease in fluorescence is directly correlated to the amount of molecules being released.

RESULTS AND DISCUSSION

MS and HPLC have confirmed the molecular weight and the purity of the synthesised peptides which was >90%.

The SEM imaging of the adhesive polymer coating showed bead-like structures on the surface of Ti6Al4V (Figure 1), and the increase of roughness was confirmed by AFM. Fluorescence microscopy showed a uniform layer of AMP-pas (Figure 2a) and AMPs adhesive polymer coating on the surface of Ti6Al4V (Figure 2b).

Figure 1: SEM image showing polymeric coating (scale = 5 μ m)

Figure 2: Fluorescence imaging of the coated surfaces a) AMP-pas (left), b) AMP-polymeric coating (right) (scale = 100 μ m).

The stability of peptides in SBF showed that 64% of the initial AMP-pas molecules are being released from the surface after the first hour while AMPs conjugated on the polymeric surface remain stable and attached for 720 hours or more (Table 1).

Table 1: Fraction of AMP bounded on the Ti6Al4V surface over time (n = 3)

	0.5 h	1 h	6 h	120 h	720 h
AMP-polymer	0.96 \pm 0.04	0.67 \pm 0.02	0.67 \pm 0.04	0.60 \pm 0.06	0.54 \pm 0.06
AMP-pas	0.47 \pm 0.03	0.36 \pm 0.05	0.11 \pm 0.02	0.05 \pm 0.05	0.01 \pm 0.02

CONCLUSIONS

Peptide aptamers and polymeric adhesives produce a linkage between the Ti6Al4V surface and the AMP molecule. The conjugation of the AMPs to the polymeric adhesive creates much more stable structure than the one made with the peptide aptamer and because of this this structure has a potential to have more efficient antibacterial property than the one where the peptide aptamers are being used.

Characterising the Micro- and Nano-mechanical Properties of Ageing and Diseased Soft Tissues

Riaz Akhtar

Centre for Materials and Structures, School of Engineering, University of Liverpool, UK, r.akhtar@liverpool.ac.uk

The mechanical properties of soft, elastic-fibre rich connective tissues such as skin and arteries are known to change with age and with disease states such as diabetes e.g. arteries become stiffer, a major risk factor for the subsequent development of strokes, aortic aneurysms, and heart failure. Normal function of these tissues is critically dependent on the biomechanical properties of two main microstructural components of the extracellular matrix; stiff, fibrillar collagens, and resilient elastic fibres. However, very little is known about the micromechanical properties of soft tissues. This is caused by the disparity between the length scale probed using traditional mechanical testing methods ($10^{-3} - 10^{-1}$ m) and that at which key biological tissue components are organized ($10^{-6} - 10^{-4}$ m). The variation in soft tissue stiffness as a function of length scale is shown in Figure 1.

Figure 1 Length scale and elastic properties of soft tissues and their structural components. Superimposed

are measurements of the elastic moduli of aorta (from literature) and extracellular components at macroscopic, microscopic, and molecular length scales. A: single collagen fibrils, B: fibrillar collagen, C: fibrillin microfibrils, D: elastin, E: ferret aorta components²⁵, F: porcine aorta components, G: human radial artery, H: rat aorta, J: human aorta [1]

Most studies in the literature focus on macro-scale changes within these tissues. Knowledge of tissue properties at the micro- and nano- scale is of great importance to better understand the effects of ageing and disease on the properties of tissue¹, and to better understand the interactions of tissues with biomaterials at these length scales.

This talk will largely focus on changes with age and disease in large arteries which we have characterised with novel materials science techniques such as scanning acoustic microscopy (SAM) and nanoindentation that allow us to localise mechanical property changes at the microstructural scale. The talk will also touch upon nanomechanical measurements of soft tissues with atomic force microscopy (AFM). These data are compared with the in vivo and macroscopic response of the vessel.

Nanotubular Titania topography combined with amorphous calcium phosphate chemistry induces direct osteoblastic differentiation in mesenchymal stem cells

Robert McLister, Mura McCafferty, George Burke, Brian J. Meenan

Biomaterials and tissue Engineering Group, NIBEC, University of Ulster, Northern Ireland.

mc_lister-r@email.ulster.ac.uk

INTRODUCTION

Calcium phosphate (CaP) biomaterials, such as hydroxyapatite (HA), are recognised as an important class of bioactive compounds capable of inducing cellular attachment, proliferation and differentiation. Previous research has indicated that sputter deposited amorphous HA coatings have osteoconductive properties that can be advantageous in this regard (1). However, the non-crystalline form of CaP is highly soluble in aqueous cell culture media. Controlling the dissolution of the CaP surface layer is therefore necessary to ensure a bioactive response in long term culture. In this work, the response of mesenchymal stem cells (MSCs) to sputtered (amorphous) CaP coatings deposited onto titanium substrates with various nanoscale topographies has been determined. The role that the specific forms of nanotopography can play in controlling CaP dissolution has been determined. The *in vitro* response of MSCs to the amorphous CaP coatings over 21 days has compared to that for thermally annealed crystalline CaP coatings to further establish the role that solubilised CaP from the coating may have on MSC differentiation.

EXPERIMENTAL METHODS

RF magnetron sputtering from HA powder targets was used to deposit CaP coatings onto Titania Nanotube (TiNT) surfaces created by electrochemical anodisation of titanium coupons at 80V for 30 minutes in a solution of ethylene glycol with 0.3%wt NH₄F and 3%wt DI H₂O. Polycrystalline titania surfaces were prepared by sputtering from metal targets onto the titanium coupons. Batches of samples were annealed at 500°C to increase their relative crystallinity. Dissolution studies were undertaken by immersion in 2ml of DMEM at 37°C for 7 days. *In vitro* cell studies were carried out using mesenchymal stem cells at passage 5. Pico green and alkaline phosphatase (ALP) assays were applied at days 1, 3, 7 and 7, 14, 21 to determine cell viability and osteoblastic differentiation, respectively. Immunocytochemistry was used to identify the presence of bone related proteins at day 21 with bovine serum albumin (BSA) as a primary antibody and rabbit Polyclonal anti-Alkaline phosphatase as the corresponding secondary antibody. Samples were washed in PBS to remove any residual antibody present and then were counterstained with 4',6-diamidino-2-phenylindole (DAPI) for 2 minutes. Once mounting media was added samples were sealed with a glass cover slide and varnish. A Quanta 200 Dual Ion Beam SEM was used to image the different substrate topographies. Fluorescent images were acquired using an LSM 5 Pascal Confocal Laser Scanning Microscope (CLSM).

RESULTS AND DISCUSSION

Figure 1 indicates the topography of the TiNT surface with Figure 2 showing the surface after deposition of a CaP sputter coating. After 7 days exposure to aqueous culture media, FTIR and XPS analysis showed amorphous CaP was still present on the surface.

Figure 1. (Top left) TiNT 80V.

Figure 2. (Top right) TiNT 80V HA after 7 days dissolution.

Figure 3. (Bottom Left). DAPI (blue) and ALP (red) staining of day 21 MSC study on TiNT amorphous CaP.

Pico green assay data showed significant cell viability on all surfaces. ALP protein expression indicated that differentiation to an osteoblastic lineage occurred for MSCs cultured for 21 days on the TiNT surface coated with CaP. As shown in Figure 3, confocal microscopy of stained MSCs provides evidence for the osteoblastic character of the cultured MSC cells.

CONCLUSIONS

This work indicates the potential to induce stem cell differentiation to an osteoblastic lineage using a combination of nanotubular topography and amorphous CaP. Importantly, the ability to control the dissolution of amorphous CaP thin film coatings via nanotubular substrate topography is confirmed.

Microwave-assisted Synthesis of Calcium Phosphate Nanobiomaterials with Controlled Morphology

P.J.T Reardon^{1,2}, J. Huang¹, J. Tang^{2*}

¹ Department of Mechanical Engineering, UCL, London

^{2*} Department of Chemical Engineering, UCL, London Philip.reardon.09@ucl.ac.uk

INTRODUCTION

The performance of calcium phosphate (CaP) biomaterials depends greatly on morphology and size. For example, CaP nanoparticles can provide enhanced bioactivity.¹ Wire-like CaP can be used as biomaterial reinforcement due to excellent mechanical properties.² Recently porous CaP nanomaterials have shown high loading and favourable release properties for drug delivery.³ The use of microwave dielectric heating for chemical synthesis allows material production with altered morphologies, increased yields, narrow size distribution, and considerably reduced synthesis times. Therefore, this energy efficient 'green' process is used in the current study, to prepare biodegradable calcium phosphate nanomaterials with varied size, morphology and textural properties.

EXPERIMENTAL METHODS

Briefly, ethanol or ethanol/water solutions containing either $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ or H_3PO_4 were prepared and mixed at room temperature and pressure, then irradiated in a microwave solvothermal process (using a MARS, CEM). Material characterisation was performed using XRD, FESEM, TEM and N_2 adsorption analysis as previously reported.^{3,4}

RESULTS AND DISCUSSION

Figure 1 TEM micrographs of CaP (a) nanorods (60°C), (b) nanoplates (200°C).

CaP nanomaterials with controlled morphology have been synthesised using a microwave assisted process without the use of any toxic surfactants. The effect of solvent composition, mixing methodology, reagent stoichiometric ratio, synthesis temperature and synthesis time was systemically investigated. Single phase nanoplates and nanorods of monetite with controllable pores are produced by varying reaction temperature (Figure 1). Dimensionality (figure 2) and bicalcium phosphate composition (hydroxyapatite (HA)/monetite, Figure 3) were manipulated by changing the ratio of the $\text{H}_2\text{O}/\text{EtOH}$ solvent mixture. Three dimensional particles with minute amounts of HA were produced when a $\text{H}_2\text{O}/\text{EtOH}$ volumetric ratio of 20/80 was used (Figure 2a). Conversely, high aspect ratio (ca. 54) nanowires containing ca. 38 wt% HA were obtained with a 60/40 $\text{H}_2\text{O}/\text{EtOH}$ volumetric ratio (Figure 5b). Importantly, the quantity of HA in the high

Figure 2 SEM micrographs of CaP: (a) microparticles ($\text{H}_2\text{O}/\text{EtOH} = 20/80$), (b) nanofibers ($\text{H}_2\text{O}/\text{EtOH} = 80/20$).

aspect ratio nanowires/needles was also controlled by varying the stoichiometric ratio of the reactants, demonstrating that 1D materials with close to 100% HA can be achieved when the Ca/P ratio is increased to 1.67.⁴ The influence of particle morphology on the loading efficiency of therapeutic agents was also studied. Interestingly, for all standard proteins the loading on CaP was found to be the highest for the nanoplate materials.

Figure 3 XRD patterns of materials synthesised using different $\text{H}_2\text{O}/\text{EtOH}$ volumetric ratios of: (a) 20/80, (b) 40/60, (c) 60/40, (d) 80/20.

CONCLUSION

The findings highlight that reaction parameters can be varied in tandem with microwave irradiation to tailor the morphology and composition of calcium phosphate materials, which are of very high importance in developing excellent materials suitable for bone tissue engineering and drug delivery.

A Dual Porosity Construct for Osteochondral Modelling and Repair

Alexander A. Popov^{1*}, George Roberts², David M. Grant², Colin A. Scotchford², and Virginie Sottile¹

¹ Wolfson Centre for Stem Cells Tissue Engineering & Modelling, CBS, University of Nottingham, UK

² Bioengineering Group, Faculty of Engineering, University of Nottingham, UK

* mzxaap@nottingham.ac.uk

INTRODUCTION

Regenerative therapeutic solutions are required to address the increasing prevalence of bone and cartilage diseases within the population. Limitations of existing treatments, such as bone graft reconstructions or biomaterial implants, suggest that osteochondral tissue constructs with the ability to support differentiation of mesenchymal stem cells (MSCs) into both osteoblast & chondrocyte lineages is desirable^{1,2}. The current project aims to overcome issues arising from the divergent differentiation requirements for each lineage by providing scaffolds with spatially resolved environments, each supportive of one of these cell lineages. The work reported here describes the porogen and cross-linker optimisation for the production of bi-layered chitosan scaffolds containing two distinct pore sizes. Scaffold characterisation was carried out before cell seeding and 3D culture in a perfusion bioreactor.

EXPERIMENTAL METHODS

Porous scaffolds were produced using a freeze-gelation method from a 4% chitosan solution mixed with polycaprolactone (PCL) porogen and cross-linked using either 0.5% glutaraldehyde or 0.3% genipin solutions. Porogen microspheres were produced by an emulsion method. Porogen particles and scaffold porosity were evaluated using scanning electron microscopy (SEM) and micro-computed tomography (MicroCT). Cytocompatibility was assessed after seeding of human mesenchymal stem cells (hMSC) onto fibronectin-treated scaffolds and culture in a perfusion bioreactor for up to 3 weeks.

RESULTS

Dual porosity scaffolds were produced and analysed by MicroCT, confirming different porosity and pore size distribution for bottom, middle and top sections of scaffolds made with PCL microspheres (Table 1).

	Bottom	Middle	Top
% Porosity	74	73	73
Pore size (μm) \pm SD	287 \pm 10.5	232 \pm 17.5	196 \pm 5.5

Large (300-425 μm) pores were designed to promote osteogenic differentiation of hMSCs and smaller, (180-300 μm) pores to support chondrogenesis. SEM analysis of the scaffolds illustrated the graded pore size distribution (Fig.1), and the absence of delamination between layers.

Figure 1 SEM images of PCL porogen microspheres (A) and resulting bi-layered chitosan scaffolds (B).

Scaffolds cross-linked with genipin displayed more uniform pore morphology than ones made with glutaraldehyde. Scaffolds were then seeded with hMSCs and cultured both in culture dishes and in a perfusion bioreactor for up to 21 days. Cell viability (Fig. 2) and differentiation were assessed at various time-points to measure osteochondral lineage maturation *in situ*.

Figure 2 Metabolic activity of hMSC seeded on chitosan scaffolds (A). Perfusion bioreactor system used to culture cellularised scaffolds (B).

DISCUSSION AND CONCLUSION

A novel dual porosity chitosan scaffold was produced for osteochondral modelling. Results show that the emulsion-produced PCL microspheres permitted control over pore characteristics in the scaffolds. Subsequently, hMSC seeding methods were evaluated for optimal cell infiltration into the scaffold core to populate the construct. Scaffolds cross-linked with genipin allowed higher cell metabolic activity than glutaraldehyde, to a level comparable to tissue culture plastic. MSC differentiation analysed over 3 weeks highlighted the influence of scaffold structure on cell compatibility in 3D.

INTRODUCTION

Surgical reconstruction of functional and aesthetic defects, particularly following ablative cancer surgery, is often compromised by the limited and the associated donor site morbidity¹. A compromised vascular bed is a major obstacle for a successful uptake of a micro-vascular flap.

EXPERIMENTAL METHODS

This study presents a comprehensive radiological and histological analysis protocol to evaluate bone regeneration within a pedicled muscle flap for the reconstruction of a mandibular defect. A critical size defect (20 mm × 15 mm) was created in the mandible of ten experimental rabbits. The masseter muscle was adapted to fill the surgical defect, a combination of Calcium Sulphate/Hydroxyapatite cement (CERAMENTTM [SPINAL SUPPORT]), BMP-7 and rabbit mesenchymal stromal cells (rMSCs) were injected inside the muscle tissue². Plain Radiographic assessment was carried out on the day of surgery and at 4, 8, and 12 weeks postoperatively. At 12 weeks, the animals were sacrificed and cone beam computerized tomography (CBCT) scanning, micro-computed tomography (μ -CT), and histological assessment were performed.

RESULTS AND DISCUSSION

Clinically, a clear layer of bone tissue could be identified closely adherent to the border of the defected area. Sporadic radio-opaque areas within the defect were detected radiographically. In comparison with the opposite control side, the estimated quantitative scoring of the radio-opacity was $46.6\% \pm 15$, the mean value for the volumetric assessment of the radio-opaque areas was $63.4\% \pm 20$. The micro-CT analysis revealed a thinner trabecular pattern of the regenerated bone with more condensed trabeculae than the average number/mm³ of the surrounding bone. Histological assessment showed areas of bone formation and remnant of residual bone cement were observed throughout the muscle and connective tissue surrounding CeramentTM. Bone displayed a high degree of remodeling with an intricate network of woven bone within Cerament. Quantitative histomorphometry assessment reported percentage of area of bone regeneration, residual cement and soft tissue were $41.3\% \pm 14.9$, $27.9 \pm 8.3\%$ and $32.3 \pm 11.3\%$ respectively. The mineral apposition rate (MAR) was $1.29 \mu\text{m}/\text{day}$ which indicate higher rate of mineral deposition with respect to the non-operated side.

Figure 1: Decalcified histological section for area of the defect, showing the regenerated bone in top image, area of bone interface is filled with woven bone (boxes), scale bar=2 mm, A&B scale bar= 600 and 300 μm , P, L, B and An indicate proximal, lingual, buccal and Anterior wall of the defect.

Nevertheless, complete conversion of the muscle into bone and full reconstruction of the defect was not achieved. This is partially due to the physical nature of the injected cement that prevented the diffusion of the material at a micro level between the fibres of the muscle tissue.

CONCLUSION

The study provided the proof of the concept that bone formation could be induced within a pedicled facial muscle flap using an injectable biomimetic-scaffold which has clear potential applications. Further development and refinements of this approach are required before clinical use in maxillofacial bone reconstruction.

The effect of a RF/DC magnetron sputtered coating on the dissolution behaviour and osteoblast response to an Mg-Y-RE alloy

²Magnesium Elektron®, Manchester, UK

(email: natasha.bhuiyan@student.manchester.ac.uk)

INTRODUCTION

Magnesium alloys have shown promise as a new generation of biodegradable metals capable of supporting bone growth and regeneration. Whilst their mechanical properties are better suited to bone placement than Ti or Co-Cr alloys, the corrosion rate of Mg alloys is often too high, leading to a loss in mechanical integrity before the tissue has had sufficient time to heal¹. To overcome this limitation, we used a RF/DC (Radio Frequency/Direct Current) magnetron sputtering technique to fabricate a coating on a biomedical Mg-Y-RE (magnesium-yttrium-rare earth alloy) from the Elektron SynerMag® range, which has already demonstrated excellent corrosion resistance in simulated body fluid (SBF). In this study, we characterised the chemical and phase composition of the coating, as well as its effect on the dissolution behaviour and osteoblast response to SynerMag®.

EXPERIMENTAL METHODS

Material preparation: SynerMag® was manufactured by Magnesium Elektron® in accordance with Elektron SynerMag® technology. Ti, TCP (tissue culture plastic) and glass coverslips were used as controls. **SBF preparation:** A solution of SBF was prepared according to Kokobu's method². **Coating fabrication:** Magnetron sputtering was carried out by Eminite®, Nottingham, UK using a commercial vapour deposition system. In the system, a DC pulsed bias voltage of -25V was applied to the samples whilst RF power at a density of 3.8Wcm⁻² was simultaneously applied to a hydroxyapatite target. This was used to deposit a 300nm thick coating on the samples. **Heat treatment:** Samples were heated at a rate of 5°C/min in wet Ar for 12hrs at 570°C, then cooled to room temperature. **Coating characterisation:** FTIR (Fourier Transform Infra-Red) and XRD (X-Ray Diffraction). **Dissolution study:** Samples were immersed in SBF for 7 days at 37°C and analysed using SEM (Scanning Electron Microscopy), EDX (Energy Dispersive X-ray) and ICP-AES (Inductively Coupled Plasma- Atomic Emission Spectroscopy). **Cell culture:** Human osteoblasts (HOb, Promocell, Germany) were seeded at 50 000 cells/cm². **Proliferation and cell spreading:** PicoGreen®, Live-dead assay® (both Invitrogen, UK) and ImageJ. **Mineralisation:** BMP-2 ELISA (R&D systems, UK), alkaline phosphatase (ALP) (SigmaFast™ p-Nitrophenyl phosphate), Osteocalcin ELISA (OC) (Invitrogen, UK). **Statistical analysis:** Two-way ANOVA with Bonferroni post-test.

RESULTS AND DISCUSSION

Characterisation of the coating after heat treatment revealed hydroxyapatite phases that had undergone both carbonate substitution and dehydroxylation into β -tricalcium phosphate and β -dicalcium pyrophosphate.

XRD also detected a highly crystalline Mg₂Ca phase that may have formed as a result of Mg diffusion into the coating during heat treatment.

In the dissolution study, spherical crystals composed of interlocking plates were observed on the coated samples after 7 days immersion in SBF (Figure 1a/b). EDX analysis of these crystals showed these were composed of high levels of calcium, oxygen and phosphorus. Both the morphology and composition of these crystals are characteristic of octacalcium phosphate (OCP), which is considered a pre-cursor to apatite formation. ICP-AES analysis of Mg²⁺ release from bare and coated SynerMag® over 7 days, showed the coating improved the overall dissolution resistance of SynerMag®.

HOb proliferation studies conducted over 21 days, revealed significantly greater cell numbers and surface spreading on coated SynerMag® than bare SynerMag®. In addition, the coating appeared to stimulate mineralisation, as BMP-2 secretion, ALP activity and OC secretion were significantly higher on coated SynerMag® than bare SynerMag® and the Ti and TCP controls.

Figure 1 (a) OCP formation on coated SynerMag® after 7 days immersion in SBF (b) magnification of OCP crystals

CONCLUSION

Our findings demonstrate the RF/DC magnetron sputtered coating improves the initial dissolution rate of SynerMag® and also promotes the deposition and growth of the apatite pre-cursor, OCP, in SBF. When cultured with osteoblasts, the coating improved osteoblast adhesion and also, stimulated BMP-2 secretion, ALP activity and OC secretion during the first 7 days.

The Innovabone project focuses on developing a novel biomimetic scaffold for bone repair applications¹. Using the 2PP process, a scaffold with a highly uniform structure and pore size has been developed. The proliferation and differentiation potential of MSCs on these scaffolds have been characterised as a part of the Innovabone project.

INTRODUCTION

The Innovabone project is a collaborative EU project that aims to develop a 2-step biomimetic product that consists of a bioactive scaffold and a bioactive self-setting gel, which will provide a microenvironment that promotes bone repair. Using a 2PP (two photon polymerisation) method, scaffolds consisting of different lactic acid (LA) and caprolactone (CL) ratios were produced. As a part of the wider study, the paper presents biocompatibility testing performed on identical scaffolds produced by 2PP but with different LA:CL ratios. Cell proliferation and osteogenic differentiation have been quantified to characterise the response of progenitor cells to this novel material.

EXPERIMENTAL METHODS

Scaffold Production – Scaffolds were provided by IBA based on a 2PP process². An ethyleneglycol based CL-LA degradable copolymer was end-capped with photo-reactive methacrylation groups by stannous catalysed ring-opening polymerisation. Three different LA:CL ratios were investigated as well as differences in molecular weight. Samples were coded LCM3, -4 & -6.

Cell Culture – human mesenchymal stem cells (MSCs)³ were seeded at a concentration of 1×10^6 cells per scaffold and cultured in DMEM supplemented with 10% foetal calf serum, 1% L-Glutamine, 1% non-essential amino acids, 1% penicillin/streptomycin, 0.1 μ M dexamethasone, 50 μ M ascorbic acid phosphate, and 10 mM β -glycerophosphate at 37°C and 5% CO₂.

Alkaline Phosphatase (ALP) (SigmaFAST) - was performed according to the manufacturer's instructions.

Alizarin Red – 1% alizarin red was added to samples and incubated for 20 minutes before wells were washed with PBS and stain was extracted using 100 μ l destain (20% methanol, 10% acetic acid, 70% distilled water). Quantification was at 405nm absorbance.

RESULTS AND DISCUSSION

The ALP activity and mineralisation of cells of the scaffolds is shown in figure 1. After 21 days there was no significant difference between the ALP activity on the different scaffolds ($p > 0.05$), but at earlier time points LCM3 had a significantly quicker increase in ALP activity than LCM6 ($p < 0.05$). This was also

demonstrated in the mineralisation of cells as the alizarin red staining on LCM6 scaffolds was only 69% of that on the LCM3 scaffolds. This may be due to the increased CL component in LCM3 compared to LCM6, which creates a more hydrophilic scaffold and promotes better cell attachment and colonisation of the scaffold.

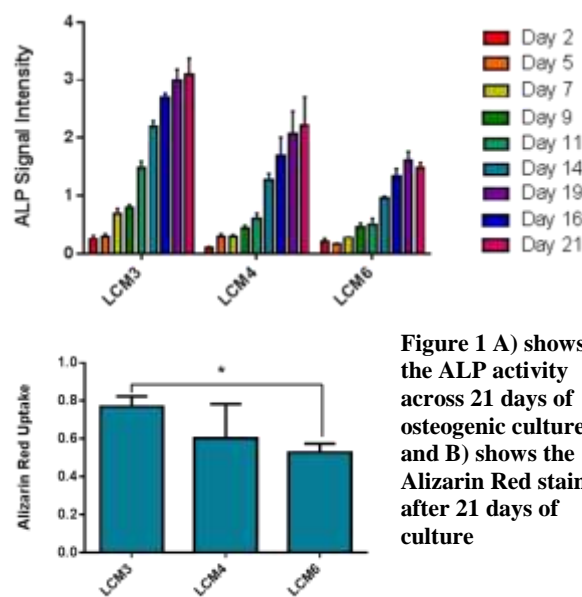

Figure 1 A) shows the ALP activity across 21 days of osteogenic culture and B) shows the Alizarin Red stain after 21 days of culture

PrestoBlue and Neutral Red assays were also performed at the same time intervals but no significant difference ($p > 0.05$) in the proliferation was observed between the scaffolds when seeded with the same starting concentration of cells.

Preliminary mechanical testing data has also shown these scaffolds to have desirable mechanical properties for bone repair applications.

CONCLUSION

All three types of scaffold were capable of supporting cell proliferation and osteogenic differentiation of MSCs over 21 days and are promising candidates for bone repair applications.

Investigation into the Ability to Accurately Mimic Natural Extracellular Matrix Using Artificial Electrospun Scaffolds

Kirstie Andrews^{1*}

^{1*}School of Engineering, Manchester Metropolitan University, UK K.Andrews@mmu.ac.uk

INTRODUCTION

The field of tissue engineering is constantly seeking to create scaffolds that reproduce the structure, properties and functionality of the tissue they are replacing. Research has determined that the behaviour of cells within these tissue structures is induced by the nature of the extracellular matrix. This natural structure (nano-, micro- and macro-scale) significantly influences the cellular migration, growth and phenotype. This fibrous architecture, particularly the exact organisation of the collagen, also plays a significant role in the biomechanical functioning of the tissue¹.

Many research groups are investigating the ability to artificially replicate this matrix; electrospinning is one technique capable of producing such structures. It allows a high degree of control over the process, and ultimately the scaffold structures and properties, with these directly inducing predictable cellular behaviour for a range of cell types and long-term culture periods². There is much debate over the use of aligned or random electrospun fibres, and their optimum arrangement and structure for particular tissue applications.

It is well documented that electrospinning can reproduce the range and scale of extracellular matrix structure and properties; however, the exact mimicry or uniformity of the architecture itself has not been investigated. Therefore, the aim of this research was to compare a range of aligned and non-aligned electrospun scaffolds with natural extracellular matrix, and to assess the similarity with the 3-D architecture and structural organisation of the fibres.

EXPERIMENTAL METHODS

Artificial Scaffolds
